To summarize the results of tests mentioned in this article and the experience of important roads in different parts of the country, it has been demonstrated good practice to reclaim cast iron car wheels with flat spots up to $3\frac{1}{2}$ in. long, provided the wheel has not made too great a mileage. The economy of the practice also depends on finding enough wheels to keep the grinder busy the full working day. Twenty-four pairs of new cast iron passenger car wheels can be ground in an eight-hour day and actual experience has demonstrated that these wheels should unquestionably be ground before use to insure a round, smooth tread, concentric with the journal. Extension of the grinding practice to new freight car wheels depends on whether the decreased flange wear, due to heavy wheels of equal diameter, would make it pay to grind mated wheels of the same taper size. That it is possible to grind steel car wheels, has been demonstrated beyond a question of doubt, but in actual practice it is probable that the grinding method can be more profitably used in the case of a cast steel wheel rather than a wheel with wrought steel tires. The manifest advantages of grinding car wheels in general have been appreciated and taken advantage of by leading trunk line railroads, and it is reasonable to believe that many smaller roads could benefit by the practice.

EXHAUST PIPE VALVE

Some months ago the Ann Arbor Railroad put into use an exhaust pipe actuated by fluid pressure, as shown in the illustration, and at the present time this railroad is having two locomotives built by the American Locomotive Company at their Dunkirk works that will be equipped with exhaust pipes of this design.

By referring to the illustrations of this device it will be seen that when the throttle valve is open steam is supplied to the connection, furnishing pressure required for the operation of the exhaust pipe valve. When vacuum relief valves are used air is admitted to the cylinder in the usual way, and no gases or cinders are drawn into the valve chamber from the smoke box. When vacuum relief valves are not used, and while the reverse lever is in the direction of movement of the locomotive, the cylinders are converted into vacuum pumps, which action works as a vacuum brake tending to retard the movement of the locomotive.

When relief valves are used and the reverse lever is placed in the opposite direction to the movement of the locomotive, the cylinders act as air compressors and the air reservoir may

be charged automatically with compressed air without the possibility of drawing any fine particles from the smoke box that might be considered detrimental to the air-brake mechanism. If the locomotive is handled dead in a train a separate connection is provided to the passage leading to the exhaust pipe valve, which may be connected to the brake system so that when charged the exhaust valve will be held off its seat

Arrangement of Pipe Connecting to Exhaust Stand

and the locomotive may be moved in either direction without difficulty.

This exhaust pipe valve is the invention of J. E. Osmer, superintendent motive power of the Ann Arbor Railroad, who has applied for patents covering the device. It is claimed that its use will result in a considerable saving in valve oil

Exhaust Stand With Valve

and a reduction in wear on valve rings, cylinder packing, piston rod packing and valve chamber bushings.

It is further stated that this exhaust pipe valve is particularly applicable to locomotives operating over heavy grades, where they are required to drift for long periods, causing the steam passages to become clogged with carbon and particles from the smoke box.

RAILROADS NEED MODERN MACHINE TOOLS

More Critical and Scientific Attention Must Be Given to the Upkeep of Cars and Locomotives

BY ROY V. WRIGHT
Editor, Railway Mechanical Engineer

Nobody Knows How Old They Are

THERE is no question about the seriousness of the transportation problem. Production is today greatly restricted because of the lack of adequate transportation facilities, coupled with the fact that the existing equipment is not being used with the greatest possible efficiency.

There are very good reasons for the situation in which the railroads now find themselves. In the first place, for the early part of the year up to the time of the outlaw strike, the roads handled more traffic than ever before in a corresponding period. More traffic is being offered to them now than ever before. In the second place, the roads found it necessary during the war to work their facilities and equipment to the very limit, and because of this and the lack of labor and material they naturally were unable to maintain their properties in the best condition. In the third place, there was very great uncertainty until the last moment as to just when the roads would be handed back to their owners and under what conditions. It was, therefore, of course, impossible for the managements to make the necessary contracts for the new equipment and facilities which are so greatly needed at this time. Indeed, even today they are more or less at sea as to how to finance themselves except for a few of the more prosperous roads. The Pennsylvania, with its splendid property, had to pay 7½ per cent on its \$50,000,000 bond issue, and yet this sum covers only a small part of its needs. Congress has provided a revolving fund which is not at all adequate so far as meeting the present needs of the railroads is concerned, and which cannot be made use of by the weaker roads because they are unable to furnish the right kind of security.

Fortunately, Congress and the public at large are thoroughly aware of the necessity of restoring the credit of the roads so that they will be in a position to finance themselves in the future. The extent to which credit will finally be restored will depend upon how fully the enlarged and reorganized Interstate Commerce Commission will discharge its responsibilities in seeing that the roads are given adequate rates and that the Transportation Act is interpreted in such a way as to develop rather than restrict the activities of the roads.

Even those roads which have ordered equipment are being embarrassed because they went into the market so late that

the other industries beat them to it, and in many instances they will have difficulty in getting early deliveries unless some sort of priority arrangements can be agreed upon. What good will it do the industries if they secure material which is needed by the railroads, and which, if assigned to the railroads, would enable them to increase their capacity so that they could handle a larger part of the output of the industries.

So much for the problem in the large.

Better Use of the Equipment

There are many ways in which better use can be made of the equipment and facilities which the railroads now have. Shippers can cooperate to a very much greater extent than they are now doing in the prompt loading and unloading of cars. Splendid cooperation was given during the war, but since the signing of the armistice much less interest has been taken by many of the shippers. It is now more than ever necessary that the cars be loaded to their full capacity and that they be loaded and unloaded as quickly as possible. The Interstate Commerce Commission will undoubtedly take steps to inaugurate practices which will be helpful in this direction, but it will also be necessary to secure and retain the hearty and cordial interest of the shippers.

The railroad managements must do their full part in getting better use from the facilities and in increasing the efficiency of operation. With the present labor conditions this will be a most difficult task. The men believe that they have not been treated rightly as to compensation, and are more or less impatient with what they believe to be the slow progress on the part of the Labor Board which was provided by the Transportation Act. Naturally they are not doing their best work. On the other hand, they must undoubtedly be awakening gradually to a realization of the fact that the slackening up of their efforts is an economic waste, and that it is forcing living costs higher and higher. The managements must not only win them over and get them to see the problem in the right light as related to the good of the country as a whole (and therefore themselves), but they must adopt an aggressive program to train and develop the new and inefficient men that they have had to employ to replace those skilled men that have been taken away from them by the industries which could afford, or felt they could afford, to pay much more for the services of these men than could the railroads.

*An address before the National Machine Tool Builders' Association at Atlantic City, N. J., May 20, 1920.

Cars and Locomotives Must Be Kept Fit

Railroad managements learned a most severe lesson when they tried to handle the tremendous increase in traffic after our country entered the war. They learned that no road could work efficiently or anywhere near its capacity unless the cars and locomotives were maintained in first-class operating condition. Under-maintenance and weak equipment mean breakdowns on the road, delays to traffic, damage to freight, and abnormal increases in the cost of operation. The thing that today is necessary more than anything else is that the roads should concentrate upon the care and maintenance of their cars and locomotives in order to get the very best possible returns from such labor and the small amount of money which is now available. This means that the weak spots must be located and strengthened one by one in order that the effectiveness of the transportation machine as a whole may be developed to the highest possible point.

Here is where we get down to the necessity of making a most critical analysis of the machine tools and equipment in all of the shops and engine houses on every road. The financial resources of the roads at this time are such that it will be foolish and ridiculous to expend in a haphazard way any money for equipment or facilities. Every cent must be scientifically placed where it will do the greatest possible amount of good.

What Machine Tools Are Needed Today?

It is impossible to make any accurate general statement as to the present condition of the machine tools on the railroads. With the assistance of the Railroad Administration, some of the roads on which conditions were particularly bad during the war were enabled to add a considerable number of new tools; other roads whose needs were not so pressing have had to discontinue their regular programs of improvement and their equipment is today considerably below what would have been its normal condition had it not been for the war.

Frank McManamy, assistant director, division of operation, United States Railroad Administration, in speaking before the New England Railroad Club six months before the end of government control said: "The use of out-of-date tools and machinery in railroad shops—although never satisfactory—may have been in the interests of economy at the rates paid for labor before the war, but under the rates now paid the use of inefficient machinery is not only unsatisfactory but decidedly expensive. I shall not specifically refer to conditions in the different shops at the time the railroads were taken over by the government, but it is a quite well-known fact that many of them, together with their equipment, were at that time and are today almost hopelessly out of date in the matter of buildings and equipment, and that the methods which this lack of facilities make necessary are such that no manufacturing industry operated on a competitive basis could exist under. In fact, it has been stated, and with considerable justice, that \$10,000,000 spent for shops and shop machinery prior to 1917 would have made it unnecessary for the government to have assumed control of the railroads. Whether or not this statement is true, it is a fact that one of the principal reasons—if not the principal reason—for taking over the railroads was the condition of locomotives and cars in certain sections of the country which, together with insufficient terminal facilities and the effort of many shippers to use the cars as storehouses, caused such a congestion that nothing short of centralized control with complete authority could have met the situation."

Some railway mechanical departments have always had a keen appreciation of the value of keeping the machine tool and other shop facilities up-to-date and in first-class condition, and have been able to secure the approval of their managements to such programs. Other roads, because of finan-

cial conditions or lack of vision on the part of their managements, or a combination of both of these factors, have struggled along with old inadequate equipment, and whether they realize it or not have had to pay a mighty high price for so doing.

I know of one important road which has always given careful attention to its machine tools and has replaced old tools or added to the equipment whenever it appeared to be wise to do so. This road has the reputation of maintaining its cars and locomotives in the best possible condition, and such statistics as are available would appear to justify this course by the lower cost of operation and the better use which is being obtained from the equipment. On the other hand, I know of another large road which has purchased practically no machine tools for ten years. There are not a few shops in the country that have a large number of tools which can best be described by the use of the words "ancient" or "antique."

In general it is safe to say that there are very few roads that are not today in need of a considerable number of new tools, while many of the roads ought, in the interests of efficiency, to make very heavy expenditures for machine tools and shop equipment. The *Railway Age* in an article in its January 2, 1920, issue showed as a result of an extensive and careful study that to provide for the normal growth of the railroads and to bring the equipment into proper shape at least \$54,000,000 should be expended for shop machinery and tools within the next three years.

Selection of New Tools

Too large a percentage of the railway mechanical departments have in the past failed to make any thorough or scientific analysis as a basis upon which to order their shop tools and equipment. It is true that a number of them have had experts in charge of the machine tool and shop equipment, but even in equipping new shops no attempt, except in a very few isolated cases, has been made to make a thorough and detailed analysis of all of the requirements. The late L. R. Pomeroy showed how this should be done in a study which he made in connection with the equipment of the Scranton, Pa., shops of the Delaware, Lackawanna & Western. This included a listing of each operation for each piece of work in order to build four new Consolidation locomotives each month, and to make eight light repairs and thirty general repairs. The analysis included the number of pieces of each class of work which would have to be performed each month, the type and size of machine tool required for each operation, together with the average time per piece and the total days' work per month for each type of machine tool. This study, which included the machine shop and boiler shop, covered several hundred different operations, and by means of it it was possible to decide just what kind and exactly how many tools should be installed.

There are those who strenuously object to tackling the problem in this way because they insist that locomotive and car repair work differs materially from the manufacture of new work and that the repair of each locomotive presents a different combination of operations. This argument has been worked overtime and railway shop managements have got to get down to brass tacks and recognize that in dealing with the law of averages they can approximate very closely the demands that will be made on the shop each day or week. It is quite possible that the equipment at Scranton, when it was made to conform to Mr. Pomeroy's recommendations, may have needed some adjustment and rearrangement, and yet it is safe to say that it was far more satisfactory than if it had not been based on so careful and painstaking an analysis. It was possible to get away with rough and ready methods of selection in the past, but the changed conditions will require close and accurate attention to such details in the future.

Weak Spots Automatically Located

Assuming that a railway repair shop plant is already fully equipped and in operation, there is a splendid way in which its weak points in equipment and organization may be automatically located. For many years men of vision in the railroad mechanical department have insisted that shop production could be increased and certain marked economies effected by the inauguration of a shop schedule system which would in effect schedule the exact handling of each individual part in the operations of dismantling, repairing and reassembling the locomotives, so that the progress of the work as a whole would go forward uniformly and rapidly. The locomotive would be kept out of service a minimum time and any tendency to delay in the carrying on and completion of the various operations could be quickly located and remedied. In fact, it makes the shop superintendent or general foreman a real manager of the shop and automatically throws a large part of the routine work on the subordinates. One of its great advantages is that it automatically locates any weak spots in the organization and focuses attention upon them. It can be readily seen how this might result in the development of extremely forceful arguments as to why new and improved machinery is needed to replace the older tools, which, from the standpoint of production, are becoming obsolete.

It is a sad tribute to the lack of vision on the part of shop managements that it has taken so many years to awaken them to the possibilities of the shop scheduling system. Within the past year or two, however, it has been installed in a considerable number of railway shops and it is probably not too much to say that in the very near future it will be used generally in all of the larger shops at least. Such a system, supplemented by a capable machine tool and shop equipment expert, will readily locate those places where the railroads can invest their money to the best possible advantage in building up the weak spots and toning up the effectiveness of the locomotive and car repair facilities.

It is interesting to note that one important railroad system has recently started carefully to analyze the condition of each machine tool in its large shops, including among other things data as to the kind of work for which it is used, the percentage of time the machine is in use, the changes which will be necessary to increase the output 15 or 20 per cent. and recommendations as to whether the machines should be overhauled, improved, scrapped or retired to a smaller and less important shop.

On another road the mechanical department has been very successful in securing appropriations for new machine tools because the shop authorities in asking for new tools must support their requests with an analysis of how the work is being done by the old tools and just how it will be redistributed and what savings will be made when the proposed new tools are installed.

One of the great difficulties in the way of getting approval for the purchase of new tools or equipment is that under any conditions, and particularly under the present financial conditions, the executive officers must have placed before them strong, convincing arguments as to the returns which will be made from the new investment. Only in this way can a wise decision be made as to the order of precedence of the many items which come before them for consideration. The machine tool builder in trying to secure railway business should have a keen appreciation of this fact and should, wherever possible, assist the shop authorities, or those who will decide upon the purchase of the tool, to develop concrete facts as to the savings which will be effected by the installation of the new machine. In the past there has been too much rough estimating or guess work in deciding what new equipment was needed, and the average mechanical department officer has not realized the importance of backing up his requests with a clear and forceful analysis of the savings

which would be effected by the purchase of the new tools and equipment.

Where New Machine Tools Are Needed

In general, what are the weak spots in railway machine tool equipment today and where is the greatest need for new tools?

With the high wages, scarcity of labor, great increase in the cost of rolling stock, and the extreme difficulty in getting new equipment the idle time of every car and locomotive must be cut to a minimum. The weakest spot in the railway mechanical department is its engine house or engine terminal facilities. Engine houses have been outgrown because of the rapid development in the number, size and capacity of locomotives.

One mechanical department officer has characterized a roundhouse as "a dark hole with a wall around it." Mechanics have had to work under the most discouraging and difficult conditions as to light, heat, ventilation and facilities. Meanwhile, the locomotives have been growing larger and larger, and the size of parts has developed so rapidly that the workmen have found it almost impossible and very expensive to handle them with the limited facilities at their disposal. Then, too, in the interests of greater efficiency and economy on the road, various devices have been added to the locomotives which have complicated the task of caring for them. The federal boiler inspection, which was later extended to cover the entire locomotive, has added greatly to the need for additional locomotive terminal facilities and conveniences. It is quite generally recognized that the effectiveness of the locomotives could be very greatly increased on most of the roads by a thorough overhauling and even rebuilding of most of the locomotive terminals.

Incidentally, very few of the engine houses have had an adequate equipment of machine tools; such tools as they have had in most cases were passed down to them when they were discarded by the repair shops. In many instances these have been absolutely unsatisfactory for the reason that most of the tools which can be used to advantage at an engine house must be simple, rugged and accurate and yet must readily handle a wide range of work. The older, lighter tools with a narrow range of adaptability have in many cases been unsuitable for the engine house. It is a good sound investment, both from the standpoint of performing the work and of getting better service from the locomotives, to have an adequate machine tool equipment at at least the important engine houses, thus relieving the repair shops of the lighter repairs which in most cases interfere greatly with the scheduling of the heavier repair work. It is significant that a large part of the tools now being ordered by the railroads are for use in engine house work.

In looking into the needs of the repair shop proper, we find that it is true that a few of the tools which may be classed as "ancient" were so well built that by an overhauling and the application of an individual motor they may give good service for some classes of work. Here again a careful study is necessary in which proper weight must be given to each of the several factors involved. Obviously, it will be foolish to make any great expenditure on the rebuilding of an old tool if when the work is all done the machine lacks important features of modern tools in the way of strength and convenience of operation. While it would be unfair to say that the older tools as a class should be entirely discarded, it is true that there are today many tools in railroad shops throughout this country which, in the interests of production and efficiency, should be discarded and sold for junk; it is not even advisable in many cases to think of trying to use them in less important shops or in engine houses.

In one large shop which is fairly well equipped with modern tools it was recently estimated on the basis of a detailed

study that about 5 per cent of the tools were obsolete. This shop, however, represents very much better than average conditions.

It may be argued that the roads cannot afford to buy new tools to replace the older ones. This is not true in many cases, for the roads are wasting more money by keeping the old tools in service than if they were to "take the bull by the horns" and get rid of them. There are any number of tools in the railroad shops of this country that are more than fifty years old, and many that were installed in the "sixties." How any mechanical department can justify the continued use of these tools is a question which it is difficult to answer.

It is important when a road is contemplating the purchase of locomotives that it consider at the same time the additional facilities which will be required to care for the new power. The shortsightedness of overlooking this was clearly shown three years ago when the roads under great stress awakened suddenly to the fact they had steadily been adding to the number and size of their locomotives for years without making a corresponding increase in the facilities for taking care of them. Not a few roads are today years behind in their machine tool and shop equipment. This must be made up.

Many special tools are needed in the shop today to provide for the larger car and locomotive parts which have been introduced in recent years. In discussing some of these special tools a mechanical department superintendent is responsible for the statement that: "We are performing many operations on old tools which should be done on modern tools at a saving in time amounting to 75 per cent at least."

A number of roads have found it profitable to establish central manufacturing plants to produce certain parts, wholly or partially finished, which could be shipped to the repair shops and engine houses. The possibility of savings are great. Not only is the manufacturing cost very considerably reduced because of the use of special machinery and quantity production, but the operations of the repair shop and engine house are not hampered by needless work. This development has created a demand for certain automatic, semi-automatic and production tools, and the indications are that the practice will be very considerably extended.

In looking over the special departments, a great need will be found in many boiler shops for adequate punching and shearing machines and bending rolls and flanging machines sufficiently powerful to handle quickly the heavy sheets which are used in modern locomotive boilers. The need of more powerful drill presses for some classes of boiler shop work is also apparent.

Many blacksmith shops are hampered by the lack of sufficient power-driven hammers as well as suitable presses for making steel car repairs, and forging machines of sufficient capacity to make parts which are now being formed on the anvil.

How Manufacturers Can Help

Machine tool builders, particularly those making types of tools specially adapted to railroad use, have given remarkable cooperation to railroad shop managements, not only in developing the special tools but in demonstrating them and in helping in many cases to plan for the arrangement of the necessary accessories in order to get the best use out of the tools. This has been appreciated.

Railroad officers have also been keenly appreciative of the concrete data which the machine tool builders have put forth in their publicity campaigns, showing exactly how different classes of work are done on their machines and accompanied, where possible, by time studies. This has helped the railroad men to bring the advantages of the machine tools in question before their managements in such a way as to have their requisitions approved.

There have been some criticisms of railroad shops because of their not having ordered more of the very high capacity

machine tools. As one mechanical superintendent put it in discussing the problem: "The entire question of production is fully as much a question of shop management and mechanical engineering as it is of shop tools." Some mechanical department officers, for instance, have decided that it is better to smooth forge a side rod and machine only the ends than to provide a high powered machine to finish the entire rod. The machine tool builders can be helpful in assisting to work out problems of this sort.

There is another way in which the machine tool builders can co-operate with the railways. Director General of Railroads Hines, just before he retired from that position, made this statement before the National Press Club at Washington, D. C.:

"I regard the next two years as a peculiarly critical period. The opportunities for the development of discontent are very great. The increases in rates cannot inspire enthusiasm, and service is bound to be unsatisfactory, especially until a large amount of equipment can be constructed. Yet both these factors ought to be regarded as necessary incidents of the times in which we live." And again, "The prospects of success will be promising if there can be an attitude of patient support on the part of the public and a proper disposition on the part of the corporate agencies and labor agencies to cooperate with each other and with the commission."

The prosperity of the country and of your business depends on the success of the transportation machine. Will you do your part by cooperation, influence and patience to help put it on its feet?

LUBRICATION OF SOFT METAL BEARINGS*

BY W. K. FRANK

Friction is the name given to the force which opposes motion and is, therefore, ever present between the journal and the bearing. It is found in all manner of mechanical devices and, strangely enough, is one of our most valuable and at the same time most destructive forces. Without friction, brakes would lose their value and nuts would never be used on bolts. Trains would of necessity run on tracks provided with gear teeth, and we could not walk as we do now but would be compelled to find other means of locomotion. Friction, however, is not desirable in bearings. Although much experimental work has been done on this subject, the laws of friction are as yet but little understood.

The surfaces of all materials which appear smooth are in fact made up of microscopic hills and valleys. When two surfaces in contact are moved relatively to each other, the clashing of the points creates a force which opposes motion. Wear results from this action and the energy expended is converted into heat.

Fluids, as well as solids, show friction, and this has been described as the force encountered in rolling the particles of the fluid against one another. The laws of friction in fluids and solids are quite different, and these have been summarized as follows: For solids, dry or slightly lubricated, frictional resistance is proportional to the load; it is independent of the extent of the rubbing surfaces; except at very low speeds it decreases as the velocity increases.

In liquids the frictional resistance is independent of the load; is directly dependent on the extent of the rubbing surfaces; and increases as the velocity increases.

The function of the lubricant in bearings is to separate the surfaces by a film so that metallic contact does not occur. If such a separation does take place the friction resulting will

*Second article abstracted from a paper presented before the Engineers Society of Western Pennsylvania.

follow the laws for fluids. It has been well established by Tower that under conditions of perfect lubrication the journal is actually fluid borne, and in this case the laws of fluid friction may be applied. He showed that when a bearing is plentifully supplied with lubricant the friction depends very little on the load or the character of the surfaces, but is dependent on the extent of the surfaces, the velocity and the character of the lubricant.

Tower's experiments were made with the load and bearing above a journal, the lower part of which was immersed in a bath of oil. He found that the journal carried the oil between the surfaces and formed a film between them. One of the most interesting points of his experiments was noted quite accidentally. In the course of his work he had occasion to drill an oil hole at the top of the bearing and found that the oil flowed freely from it. He attached a pressure-gage at this point and determined that a pressure of over 200 lb. per square inch was developed, although his load was only 100 lb. per square inch of projected area. Later experiments showed that the pressure of the film at the top was greatly in excess of that at the sides and that it was greater on the discharge side than on the entering side. The thickness of the film has been determined as between 0.0013 and 0.0029 in.

However, in most applications such ideal conditions are not reached, and usually on starting the surfaces are in contact and subject to the laws of friction for solids. Lubrication is often interrupted or imperfect, by reason of improper distribution, and friction does not follow exactly the laws either of solids or of liquids, but is intermediate between them. This is the type of intermediate friction encountered in bearings with which the present paper deals, and it is necessarily an indefinite quantity depending on all of the named variables. It will be seen that the matter of the character and supply of lubricant, as well as the nature of the surfaces, will be important factors in determining the friction and wear of the surfaces.

Since lubrication is so vital in the matter of friction and wear, prime consideration should be given to it in bearing design. Every effort should be made to create a film, although it is not always practicable nor desirable to provide bath, flood or forced lubrication. Various methods for supplying the lubricant are in use. Drop feed lubrication, which is the simplest form, requires only a hole in the bearing through which the oil is introduced. Unfortunately, this hole is often placed at the point of greatest pressure, so that no opportunity is allowed for the establishment of a film. Introduction at the point of minimum pressure would probably reduce both wear and friction.

Saturated pad lubrication is employed in some cases, the most common example of which is the railroad car bearing. The bearing covers only the upper third of the journal and waste, saturated with oil, is pressed against it from below.

Ring or chain lubrication is used on many line-shaft bearings and on the bearings of electrical equipment. Chains or rings are provided of a diameter considerably larger than the journal and resting on it, and these run in grooves in the bearing and through a reservoir of oil. Good results have been obtained by this method, and it is claimed by some authorities that conditions closely approaching perfect lubrication are reached.

Flooded lubrication consists of pumping the oil or carrying it by gravity in large volume to the bearing and delivering it at practically no pressure. Perfect films are often obtained, and the added advantage of dissipating the heat of friction brings it into use with large high-duty bearings. Forced lubrication is used in a limited number of cases. Oil is pumped to the points of maximum pressure and a perfect film is maintained. The pressure of delivery at the bearing must, therefore, be above the pressure of the film, and ranges from 15 lb. per sq. in. to 600 lb. per sq. in.

Grease lubrication is applied principally to heavy, slow-moving machinery. Considerable friction is encountered from the lubricant itself, but under heavy pressures the "body" of the grease prevents abrasion by the tenacity with which it clings to the respective surfaces and separates them.

Oil grooves are resorted to in many bearings in an endeavor to secure a film. However, when the film is once formed the grooves are a distinct hindrance to its maintenance. Grooves should, in general, not lead into the region of maximum pressures, as in this case they may actually lead the oil away from instead of towards the place where it is most needed. Grooves should preferably be placed in the region of minimum pressures and should run parallel to the axis of the shaft. Care should be taken to round the edges of the grooves to minimize the danger of injuring the film.

In bearings subjected to heavy loads the oil or grease may be entirely squeezed from between the surfaces when motion ceases. Grooves to the pressure points will provide convenient reservoirs of grease for starting and thus prevent abrasion, and this is the only case where such grooves should be countenanced. Errors in locating grooves may be avoided, to a great extent, by keeping in mind the desirability of securing films.

Another factor in securing proper lubrication is clearance between the bearing and the journal. Where the bearing covers only a portion of the journal, the latter can be made smaller in diameter, thus providing clearance at the minimum pressure sides. This is often further increased by planing away additional metal from these sides. The amount of clearance desirable will vary with the velocity of the journal and the nature of the lubricant, but in general it can be said that too much clearance will decrease the opportunity for the formation of a film. The error, however, is often made on the other side—that is, too little clearance is provided. It should be remembered that the bearing is often rigidly held, so that with a temperature rise expansion of both bearing and journal tend to decrease the space between them.

Clearance should be provided between bearing and container, whenever possible, to allow free expansion. Without this, expansion of the back of the bearing may cause pinching off of the lubricant at the sides and what are apparently perfectly fitted bearings, when cool, may be in fact very badly fitted when they become warm.

Dissipation of heat from the bearing is a matter which is often overlooked. The heat of friction is usually carried away by radiation, but in some cases cooling is accomplished by currents of air, oil or water. Water cooling is often employed, but in some cases this is not practicable and the bearing is called upon to run at high temperatures.

Bearing design is sometimes checked up by the product of pressure, in pounds per square inch of projected area and velocity in feet per minute. Various values have been assigned, ranging from 24,000 to 1,720,000. One manufacturer of heavy machinery limits this value to 60,000 for ordinary lubrication, while 1,100,000 seems to be good practice for locomotive main crank pins.

As will be seen from some of the precautions in design, the bearing that has the best lubrication will last longest, other things being equal. Grit and dirt will often start scoring, and it may be of interest, in passing, to note that this remedy is sometimes used in curing hot boxes. Bearings are occasionally so tightly fitted that little lubricant can enter between the surfaces. Minute oil grooves may then be secured by introducing a small quantity of powdered emery, which makes circumferential scratches on both the journal and bearing surface. Care should then be used in clearing the emery from the lubricant, as abrasion to a serious extent may be caused. Clean bearings, well lubricated and kept in alignment, should give little trouble when properly designed.

RAILWAY EQUIPMENT IN SOUTH AMERICA*

Difficult Operating Conditions in Peru Have Led to the Development of Unusual Features

BY J. P. RISQUE

LIKE the old mariner who is said to have been able to detect the class and relative importance of a distant schooner by "the cut of her jib," a practical locomotive man inclines his opinion of a road in the direction of his impressions of its rolling stock. The track may be exceptional, the terminal facilities elaborate, but, as a staunch maintainer of his department's claim that "locomotives are the only things that really earn any money on a railroad" he will reduce his impressions to terms that are expressed in figures that relate to the prime mover. Naturally, those impressions will be tempered somewhat by the showing that is made in the road's cad department—otherwise the alleged truth of his slogan could not even have the importance that the other departments grudgingly allow it.

To this individual the size, type and class of power on a line, as well as the cars, their upkeep and apparent condition is the outward sign of the spirit of progress or its absence. He will just as naturally look for superheaters, feedwater heaters and other modern improvements that create economy and shorten time that doesn't produce, as he looks for sugar in his coffee. Their general omission is to him an index of the management's mental process toward the cost of the haul.

As the average American railroader's knowledge of the lines outside of his own country, and particularly of those in South America, is meagre, the reports that reach him from time to time from tired travelers in those parts to the effect that "the cinders from a wheezy old wood burner at the head end of the train, set fire to the clothes of the passengers in the coaches behind," have not perceptibly increased his interest in either the railroader or his equipment in those lands. This scant understanding of the extent and importance of some of the real transportation achievements on the continent to the south of us has, in a measure, deprived him of the benefits of some of the lessons they hold, chief

among which is the lesson of thoroughness in every thing that is done.

British Equipment Predominates

A student of locomotive design who is more or less familiar with the principal characteristics of British practice would become impressed with the dominance of the latter

Cross-Compound Consolidation on the Southern of Peru Equipped With Dalzell Feedwater Heater

types, particularly in certain sections. That this condition is logical is attested by the fact that about 65 per cent of the roads are owned and controlled by British capital and operated by British nationals. And on other roads, operated by the governments of the respective countries or by other non-British owners, the type referred to is largely represented, due partly to the influence exerted by the performance

*This is the first of a series of articles by Mr. Risque, who has recently returned from a trip through South America as an editorial representative of the *Railway Mechanical Engineer*.

of those types and partly to the American builders' ancient indifference to the unexpected possibilities. Thus, in a trip of inspection over some of South America's principal lines, an observer would come to look upon the appearance of any great number of American built locomotives—and particularly of American design—as an exception, not a rule.

Descending the West coast the first important railways encountered are the various government owned short lines of Colombia, the nucleus of what will probably be, some-day, a unified system. Further south is the narrow gage Guayaquil & Quito line operated by an American company between the two points named, in Ecuador. As neither of the aforementioned roads present significant differences in equipment or manner of operation, at least on a scale comparable with that which follows, a description of them is omitted.

The Railways of Peru

Among the very interesting contributions to the exception previously mentioned, is the equipment on the lines in Peru, controlled by the Peruvian Corporation, a British institution throughout, whose directorate resides in London. An American railroader would feel perfectly at home here, for

The General Manager's Private Car, Built Complete at the Arequipa Shops

with the exception of a few light side tank suburban locomotives of British design, the entire equipment is of American manufacture and style. For convenience in this description the corporation's holdings can be said to be located in three districts. The first comprises some lines operated north of Callao—unrelated short feeders from mines or sugar plantations, to the coast. The central of Peru, running northwest from Callao to a point on the roof of the world, called Oroyo, thence southwest a short distance to Huancayo, makes up the second section; and the Southern of Peru from Mollendo, inward to Lake Titicaca to Cuzco in one direction and La Paz in another, carrying its freight and passengers across the lake in its own steamers, composes the third section.

Aside from the shortness of the trains which are limited to four cars by the average lengths of 21 switch backs traversed in the run of 247 miles from sea level to an altitude of 15,665 ft.—all in seven hours—there is little to be mentioned as the equipment is American throughout. As words are inadequate to describe the scenery on this ride it will suffice to say that if this asset could be capitalized this road would emerge from the position of an obscure carrier of supplies from the Port of Callao to Lima and the mining camps in the skies above it, to the richest passenger carrier in the world, compared with which the present receipts from copper carried down the hill would be insignificant. This section is more a study for the locating engineer than a student of operation, many of the former of whom it is said can with difficulty conceive of the brain that planned it, much less comprehend the determination of the celebrated

engineer who put it through. It is the engineering wonder of South America.

The third section referred to—the lines known as the Southern Railways of Peru—while somewhat less picturesque, offer many items of interest to a practical railroader. Here, too, will be found locomotives and cars and other interesting devices of American types and manufacture in the motive power department, where, during the war the chief mechanical engineer of the system, H. E. Dalzell,

Standard 30-ton Box Car Built at Arequipa Shops

adequately proved the truth of the old assertion that "necessity is the mother of invention." For materials were scarce and some indispensables were unobtainable at any price. And as this period of distress seems to have so efficiently "put them on their own," they have been at it ever since. As a consequence much of the previous dependence on outside manufacturers has given place to home-made equipment, of which there is a variety.

Modern Equipment on the Southern of Peru

At the Arequipa shops, the principal repair headquarters for the line, the road turns out castings up to five tons, casts, assembles and applies complete superheater units among which are sets running successfully with the original slide valves aided by a special lubricating system. There has

Feedwater Heater Designed and Built by Motive Power Department at Arequipa Shops

been designed and manufactured complete by the chief mechanical engineer at this point a feedwater heater which has been applied to a 4-8-0 two-cylinder compound freight engine whose operating records showed an economy of seven per cent before the installation. The engineer on this particular locomotive in his competition for the monthly "fuel economy prize" has been handicapped 10 per cent over

his fellows—but he always gets away with the money! As a consequence, the chief mechanical engineer is busy with materials for equipment of the remaining engines. The heater is mounted in front of the stack; the feed pump, the steam end of which is an old Westinghouse 9-in. cylinder, is mounted upon the right hand running board. The exhaust nozzle was reduced seven per cent for the purpose and a branch pipe carries a portion of the exhaust through a pipe in the top of the smoke box, over into the top of the drum of the heater. With water in the tender at 63 deg. F. and the pump running at 15 strokes per minute, the feed-water temperature is raised 140 deg. and passes under the check valve into the boiler at 203 deg. Results from the operation of this engine, No. 57, show that during five months' running repairs to the heater cost \$5.10, while the engine hauled 178-ton trains up-grade against 160 tons hauled by those of the same type and size not so equipped. The kilos of coal per kilometer show 9.2 per cent economy in favor of the heater; kilos of coal per ton-kilometer re-

Feed Pump for Dalzell Feedwater Heater

veal an economy of 18.2 per cent. The actual saving in coal is 2.09 kilos per kilometer. As these engines are making 30,000 kilometers a year the total saving is about 62 tons a year, which at the prices paid for coal in these parts (56.77 soles per ton) is equivalent to approximately \$1,775.

All front ends have been standardized, electric headlights are used on most of the passenger engines and orders for additional sets are being put through from time to time. All the corporation's cars are manufactured complete at the Arequipa shops and the only parts imported for the trucks are rolled steel wheels, chilled cast iron having been found impracticable owing to brake shoe friction and consequent excessive heat which cracked them. Seventy-one 30-ton box cars

have been turned out at the Arequipa shops as well as twenty-three 50-ft. first-class passenger coaches, the latter electrically lighted from locomotive headlight dynamos. The plant is now preparing for the construction of two 60-ft., six-compartment sleeping cars and a 60-ft. diner, and a possible purchase of four locomotives was said to be under consideration. In and around the roundhouse and repair shops as well as coach building shops at Arequipa there is an air of effectiveness that is produced with an outlay that is meagre. The observer with his eye peeled for the reasons

Truck Made Complete at Arequipa, Except Schoen Steel Wheels

will find that in the absence of steam for the blacksmith shop hammers (the works are run by electricity purchased from the local city power plant) compressed air from a motor-driven compressor is used. This air, piped around the place keeps the drop yard's 10-ton locomotive crane, as well as the air tools busy—of which there appear a variety. Three sets of Lincoln arc welders and an oxy-acetylene outfit are in use and there was in process of assembling, for use at outside points, a portable outfit comprised of a four-cylinder gasoline motor truck engine, belted to a dynamo and arc welding set.

Difficult Operating Conditions in the Andes

Grades and curves are the principal handicaps to the hauling problems on this mountain road. The coal consumption on the grade has been reduced by the use of superheaters, some of which are in use and others being put

Wear on Axle End and Journal Box Caused by 90-Meter Curves

cn as fast as engines are shopped, as well as by the use of the feedwater heaters described. Ten tons less dead weight in tenders is effected by cutting down the tender water space. Ninety-meter radius curves, with which the line is plentifully supplied, have played havoc with axles, cutting off the collars at the ends, making short work of brasses and boring out the inside faces of journal boxes where the hub of the wheel exerts its force in the end thrust.

A cure for this difficulty was found in the chief mechan-

ical engineer's design of a special journal box lid which has a lug cast on its inside face, on the surface of which is cast a bed of anti-friction metal about $\frac{3}{4}$ in. thick. The lid is held down on the box by two $\frac{7}{8}$ -in. bolts and raised letters on the lid admonish all concerned to "always keep the nuts screwed down." This device is being applied to all rolling stock gradually and is automatically prolonging the life of journals, boxes and brasses.

Old axles are reclaimed in the blacksmith shop by heating the ends, upsetting them and welding on a lug. A horizontal ram hung from the steel girders of the shop roof is operated by a cable attached to a clutch; the shifting of a lever swings the ram and the reinforced axle is then turned down in a lathe. One man and two helpers turn out reclaimed axles at the rate of five in seven hours.

Section of Dalzell Journal Box

Contrary to the general impression, the Southern, like most all of the South American lines, has had its struggles with the fuel problem. Coal has been costly and difficult to obtain. Previous to the outbreak of the war briquettes from Wales formed about 57 per cent of the supply at a cost of about \$50 a ton at Mollendo. Since the war Fairmont, Pocahontas and Vancouver coal has been used. The mechanical department is now preparing to convert all power to oil and it is expected that by the end of 1920 Peruvian oil will be used universally on the system.

Water conditions are said to be fair all along the line with the exception of bad conditions on the Mollendo-Arequipa divisions, which are supplied by a pipe line from Arequipa all the way. Plans are under consideration by

Coal Car Built at Arequipa Shops. Note the Door Fasteners

the management for improving this condition in some manner, either by the installation of individual water softening plants or a single unit at Arequipa.

All passenger trains are equipped with Westinghouse air brakes which combine straight air and automatic features. Freight trains are hand braked exclusively owing to the existence of a large number of old cars to which it has

been deemed impractical to apply air brakes. For the same reason, link and pin couplers are found, old bodies being of insufficient strength to support the draft gears. As new equipment is built it is expected that the line will gradually outgrow the present forced limitations and will become standardized throughout.

Included in the interesting variety of equipment found on this railway are two Hudson supersix motor cars, equipped with flanged steel wheels with brakes on all wheels for the entertainment of tourists who are willing to pay the price for the novelty of a fast ride over the Andes. A testimonial of their worth and continued patronage is evidenced by the care with which they are maintained and their availability at a moment's notice. The operating results for these two cars show that they make 31 kilometers to a gallon of gasoline.

The Electrified Division

The electric division, running from a point called Alto, within nine kilometers of the terminal in La Paz, is constructed along a sheer cliff and the descent is 1,500 ft. with $6\frac{1}{4}$ per cent grade. Its operation required a choice between Shay type locomotives and electricity and the latter was chosen as the most acceptable solution of the problem. The power house is located slightly above the city of La Paz

Two 2-Ton Electric Locomotives on the La Paz-Alto Section

at an elevation of 13,000 feet and contains two Boleneder type Deisel engines which are capable of the development or 400 b.hp. at sea level. These engines are direct coupled to two 180 kilowatt, 550 volt General Electric generators running at 165 r.p.m. There are also two 400 hp. producer gas engines belted to two 150 kw. generators for emergency use. A 1,160 ampere hour capacity Tudor battery is run in parallel with the above plant and is charged and discharged through an automatic reversible booster. The line is of ordinary .0000 grooved copper wire, supplemented by ample feeders tapped into the trolley wire at intervals of every half kilometer. The motive power on this division includes two 20-ton, 550 volt D.C. electric locomotives of the type illustrated, four 4-wheel trolleys and four 4-motor combination baggage and express cars.

Equipment on the Lake Division

Puno on the west and Guaqui at the east end of Lake Titicaca, both being terminals on the division from Juliaca to La Paz, are adequately equipped for quick transfer of freight from cars to ships and vice-versa by means of batteries of four 5-ton steam cranes on runways. The loading record at Puno is 750 tons per vessel, in one day. Passengers descending the west coast, en route to La Paz, generally

arrive at the lake in the evening, and cross the lake during the night, but the picturesqueness of the scene is available to early risers the next morning.

The corporation operates four steel steamers on the lake.

erated daily between Mollendo and Arequipa as well as a minimum freight service of two daily trains of 175 tons maximum up-grade, each way. Three passenger trains a week of six cars each and chair cars twice a week make the

Coaling Steamer Inca at the Puno Wharf

The largest ship in the fleet is the Inca, a 750-ton capacity cargo boat, built to British Admiralty specifications with twin screws, forced draught and superheater equipment and having accommodations for 70 first class passengers. This boat is generally used in the service between Puno and Guaqui, direct. The Coya is a 450-ton capacity boat, also with twin screws and a first class passenger accommodation of 74 and likewise makes direct runs. The Yavari, a 165-ton capacity ship is used as a coasting vessel, making about twelve local calls around the lake, discharging imported supplies from Mollendo and picking up wool, potatoes and other native products. Under the direction of the chief mechanical engineer of the line, this ship was recently entirely reconstructed and lengthened and the original steam engines were replaced by a 320 hp. Bolender internal combustion engine

run from Arequipa to Puno. Four or five sections of freights of 175 tons each are sent up to the highest point called Pellones, beyond Arequipa, where the accumulated loads are hauled by one locomotive to Juliaca whence the loads are distributed for Puno and Cuzco.

BOILER CORROSION

In a paper on the Protection of Boilers from Corrosion, abstracted in *The Engineer*, E. Hoehn, engineer-in-chief to the Swiss Association of Steam Boiler Owners, of Zurich, describes experiments made by the association during the years 1915 to 1917 with a view to finding out the best means of preventing internal and external rusting. After dealing with relatively expensive methods, it passes on to the consideration of the use of protective coatings of various kinds. Some are proprietary compounds and some are not, but the two which appear to give the best results are cement and a mixture of 75 parts by weight of distilled gas tar and graphite. The cement has the advantage that it can be applied without any special precaution, while cases have occurred of men being overcome by the fumes of tar when treating the inside of boilers.

The discussion on the employment of cement is exceptionally interesting and is supported by a number of experiments made for the association both in a laboratory and in boilers in actual use. It appears that a thickness of about 0.02 in. is sufficient, and that if the wash is brushed on to a cold boiler and given 24 hours at least to set, it will adhere very strongly to the surface—even if it be slightly rusted to begin with—and that the higher the boiler temperature the harder the coating will become.

Of the mixture of tar and graphite Mr. Hoehn says that it is of the highest importance that only distilled tar should be used, as crude tar contains destructive acids. A wash of cement on the colder parts of boilers at least is no new thing, but it is doubtful whether it will stand the frequent changes of temperature and pressure and the consequent movements of the plates. The tar-graphite mixture is no doubt flexible and might not fail in the same way, but would it endure on the hotter surfaces? Such questions as these can only be adequately answered by prolonged tests under working conditions.

One of the 400 b. hp. Diesel Engines Working at 13,000 ft. Above Sea Level, Supplying Power to the 10 km. Electric Division

for burning Peruvian oil. The fourth boat is the tug Yapura which carries 100 tons of cargo with two steel lighters of 120 and 200 tons capacity, respectively, which latter were built complete at the Arequipa plant.

Practically all of the line's freight has its origin at the Pacific port of Mollendo, thus resolving the road's hauling problem into one of an up-hill struggle from sea level to an elevation of 14,000 feet, varied only occasionally by stretches of level pampa. Five and six car passenger trains are op-

THE INSPECTION OF FREIGHT EQUIPMENT*

Maintenance of Trucks, Lubrication and Packing of Journal Boxes, Defects of Wheels and Axles

BY L. K. SILLCOX

Master Car Builder, Chicago, Milwaukee & St. Paul

ONE of the most important items to be considered to insure the cool running of journals is intelligent, systematic and periodical attention to the packing in boxes on equipment in service. Briefly, this should consist in lightly loosening up the packing with the packing iron to avoid the hardened and glazed condition which results when packing has remained too long in direct contact with the journal. This is not to be interpreted to mean that trains in service are to have the packing poked up more often than once in every five hundred to one thousand miles run, as otherwise it will result in it becoming all cut to pieces through continual jabbing and mechanical wear and tear. In explanation, trains on coast line runs may have the packing loosened up so as to come in contact with the journal or turned over with the standard packing iron at Aberdeen and Deer Lodge, as well as at originating terminals. It is the intention to change the packing in journal boxes under cars once a year, and as the date is clearly stenciled on the sides of the car showing when removal was last made, it will be necessary for car inspectors to follow this closely, and in case this is not being given the attention required they are to notify their immediate superior of the fact. Car inspectors and others are cautioned to examine the end of the journals at the centering hole to see whether they present a dry condition; if so, it is almost a certain indication that something is wrong and the brass should be removed and examined.

Wheels should be inspected to discover those having cracks, seams, flat spots, loose on axles, broken flange, chipped flange, worn flange, shelled out, tread worn, chill worn or worn beyond the condemning limit.

Lids on journal boxes should be lifted to make inspection of sponging, journal bearings and journal bearing wedges to see that they are in proper condition and journals not cut. Journal bearings and wedges should be in proper position in the box and the sponging in place well to the back of the box and up under the journal. Box lids should fit well in

place and be properly secured to exclude dirt and dust. Under no circumstances are journal box lids to be left open for any considerable time or when trains pull out for the run. A supply of the various kinds of oil box covers must always be kept at hand and inspection stations must be fully equipped with some kind of cover or lid, at least, so that each box before it leaves for movement on the line will be supplied. In case of foreign cars, where no possible pattern, either wood or metal, is obtainable, a piece of wood or old galvanized roofing should be employed.

No part of the body or truck frame or attachments shall be less than $2\frac{1}{2}$ in. above the top of the rail.

Preparation of Journal Box Packing

The standard instructions covering the preparation of journal box packing provide that the waste be carefully pulled apart and a known weight placed in the preparation vats, adding sufficient oil to completely submerge the waste (for 50 lb. of waste this will be 60 gal. of oil). The waste and oil should be allowed to stand for 48 hours; drawing off the excess oil (in above case this would be 35 gal.), leaving just a sufficient quantity to maintain the ratio of four pints of oil to each pound of dry waste. The work should be performed in a room at a temperature of about 70 deg. As the oil continues to drain, it should be drawn off from the bottom of the vat and poured back over the top of the waste, thus maintaining the proportion of four to one until all packing is used, and having the packing always ready for service. In tanks of two or more compartments, one can be used as storage for prepared packing, while the other is being used for the saturation of fresh packing.

The man in charge of the oil room should be thoroughly instructed to drain off the oil that settles in the bottom of storage tanks and to pour it back over the packing several times daily. By these instructions, it should be understood that when the oil is poured over the packing it must be equally distributed to cover the entire surface of the packing contained in the storage tank. The oil rooms should be kept

*Sixth of a series of articles on this subject by Mr. Sillcox. Copyright, 1920, by the Simmons-Boardman Publishing Company.

clean and free from dust and other foreign matter at all times, and no dry waste or wiping towels allowed to be carelessly thrown in or mixed with the packing.

In addition to these tanks, it is necessary to have a metal container to hold rolls that have been made up of dry waste which have afterwards been submerged in oil. These are rolls to be used without carrying much oil, or in other words, moderately dry, in order to have them ready to apply to boxes at all times. The standard dimensions of these rolls is $2\frac{1}{2}$ in. in diameter and about 11 in. in length. These rolls assist in better excluding the dirt in the back of boxes as well as holding the oil in the box.

A standard dope bucket should be used for handling prepared packing and nothing else. After a train of cars has been gone over by the yard or shop packer, all packing remaining in the bucket should be placed back in the storage tank until it is necessary to go over the next train of cars.

A standard packing iron should be adopted with a sharp end, and the forked end of this packing iron should be maintained in its original condition at all times, as continual use wears down this end. The packing iron should also have a lug about 12 in. from the handhold, which is used to open box lids. A suitable pulling hook is required for each packer on the shop tracks as well as in the train yards. A box packer's outfit should consist of the following standard equipment: Dope bucket, packing iron and pulling hook.

Method of Packing Journal Boxes

The packer should first place the prepared roll in the mouth of the box, using care to center the roll, then with the packing iron it should be shoved back evenly under the journal, so that it is in the proper position when it reaches the extreme back of the box. The packing should be picked up by hand and placed across the entire mouth of the box. This is absolutely necessary in order to keep the packing evenly distributed in the operation of placing it in the box. This method insures an even distribution while being placed in the box, due to feeding the packing in a continuous strand under the journal (not on the sides), until the box is completely packed to the center line of the journal, straight down from the inside face of the collar. Balance of box to be packed loosely with portions of prepared packing and to be separate from that back of the collar of journal. This is to prevent packing under the journal from working forward and away from rear end of box.

When wheels are applied the journals should be thoroughly cleaned, the bearing surface of the brasses coated with oil and a dust guard inserted. No waste, either dry or saturated, should be used in oiling the journal bearing, this to avoid any particle of waste or foreign substance remaining on the journal bearing when it is applied. A film of clean oil should be provided by pouring it from a can. Tight-fitting dust guards should be applied in all cases when wheels or journal boxes are applied. Where new journal boxes or integral truck sides are applied, the interior of the boxes should be free from scale and sand or any other foreign substance.

When the movement of cars is reversed while enroute it is found that the packing works to the rising side of the journal in a great many instances and will remain in that position in the reverse movement if not adjusted, causing journals to heat, as packing in this position will not feed oil to the journal. When box lids are found difficult to open, assistance should be obtained. In no case must a box be jacked up in the yards or shops without first removing all the packing. When a car is found with a hot box or a mark indicating a hot box, a careful inspection must be made to ascertain the cause of heating. If the journal is smooth, apply a new brass and repack with prepared packing. If the journal is rough, a new pair of wheels must be applied. Under no

circumstances must a journal which has been heated be reapplied to a car unless it is in a perfectly smooth condition. A journal which has been heated sufficiently to discolor it must never be reapplied unless it is known to be perfectly safe to run.

Journal boxes of freight equipment cars must have the packing removed, the bearing examined and the boxes repacked as the cars receive classified repairs if the stenciling indicates that they have not been repacked within nine months. When newly packed or repacked, they must be stenciled as to the date and place where the work is done.

Care is to be taken to see that all new journal bearing wedges have a crown of almost $1/16$ in., and this should be maintained in order to guarantee good results in service. Wedges having the crowned top surface worn flat and smooth for a length from front to back of more than 4 in. should be removed and replaced with new wedges where practicable.

Journal bearings for 5 in. by 9 in. and $5\frac{1}{2}$ in. by 10 in. journals must not be employed in renewals unless at least $1\frac{3}{16}$ in. thick over all at the center. Journals not in service must be coated to prevent rusting. Care must be exercised in loading wheels for shipment and placing on storage tracks to prevent the flanges from coming in contact with the journals.

Truck conditions contribute very materially to the cause of journals heating on freight cars, as for example, the absence of nuts from column bolts and box bolts. Where the nut is missing from the column bolt, invariably the arch bar springs up, throwing the weight on the journal box and putting the box out of line. Where box bolt nuts are missing on trucks passing over low joints and crossovers, it has the tendency to allow the journal bearing to become unseated from the journal and bearing, also causing journal bearings to become broken. Cars with the arch bars worn at the column and box bolt holes, allow the box to cant inward causing the journal bearing to ride partially on the side of the journal. This defect of worn bolt holes is due primarily to nuts missing from bolts or nuts not drawn home, which allows the bolts to keep working upward and downward and also turning when the car is in motion.

Axles

In determining whether axles are worn beyond reasonable or safe limits to continue in service, it is well to bear in mind that the proper maximum limits generally accepted in removing them are (1) if the *fillets* at the back end of journals show less than $1/8$ in. radius on axles of 40,000 lb. capacity ($3\frac{3}{4}$ in. by 7 in. journal), less than $5/16$ in. radius on axles of 50,000 lb. capacity (4 in. by 7 in. journal) and 60,000 lb. capacity ($4\frac{1}{4}$ in. by 8 in. journal), and less than $3/8$ in. radius in axles of greater capacity; (2) if the *journal length* is increased $1/2$ in. over the standard original length when new; (3) if the *collar* is broken off or worn to $1/4$ in. in thickness or less.

When second-hand axles are applied to cars, the diameter or wheel seats and centers must not be less than the following:

A. R. A. Standard Design.

Nominal Capacity.	Limit Minimum Diameter for Wheel Seat.	Limit Minimum Diameter for Center of Axle.
140,000 lb. (6 in. by 11 in. journal).....	$7\frac{3}{8}$ in.	$6\frac{1}{2}$ in.
100,000 lb. ($5\frac{1}{2}$ in. by 10 in. journal).....	$6\frac{3}{4}$ in.	$5\frac{3}{4}$ in.
80,000 lb. (5 in. by 9 in. journal).....	$6\frac{1}{4}$ in.	$5\frac{1}{4}$ in.
60,000 lb. ($4\frac{3}{4}$ in. by 8 in. journal).....	$5\frac{1}{2}$ in.	$4\frac{1}{2}$ in. ..
40,000 lb. ($3\frac{3}{4}$ in. by 7 in. journal).....	$4\frac{3}{8}$ in.	$4\frac{1}{8}$ in.

Non-A. R. A. Standard Designs.

Nominal Capacity.	Limit Minimum Diameter for Wheel Seat.	Limit Minimum Diameter for Center of Axle.
70,000 lb. ($4\frac{1}{2}$ in. by 8 in. journal).....	$5\frac{5}{8}$ in.	$4\frac{7}{8}$ in.
60,000 lb. ($4\frac{1}{4}$ in. by 8 in. journal).....	5 in.	$4\frac{3}{8}$ in.
50,000 lb. (4 in. by 7 in. journal).....	$4\frac{3}{4}$ in.	$4\frac{1}{8}$ in.
40,000 lb. ($3\frac{3}{4}$ in. by 7 in. journal).....	$4\frac{5}{8}$ in.	$3\frac{7}{8}$ in.

A. R. A. standard axles must be used in replacing A. R. A. axles subject to condemning limits for such axles.

A. R. A. standard axles may be used to replace non-A. R. A. standard axles of like capacity when overall lengths conform to A. R. A. standard lengths, at the expense of the car owner, except that in case of delivering line defects the charge against owner shall be confined to the difference in value between the non-A. R. A. standard axle removed and the A. R. A. standard axle applied. Non-A. R. A. standard axles may be used to replace non-A. R. A. standard axles in kind until October 1, 1920, subject to condemning limits for such axles.

A. R. A. standard 60,000 lb. capacity axles, with wheel seats less than the condemning limit for such axle, but above the condemning limit for non-A. R. A. standard axles, may be replaced in kind, or may be used until October 1, 1920, to replace a non-A. R. A. standard 60,000 lb. capacity axle when the latter is of A. R. A. standard length.

When axles are removed from service on account of wheels having owner's defects, if the diameter of the journal is not at least $\frac{1}{8}$ in. greater than the limiting diameter shown, or if the journal is more than $\frac{3}{8}$ in. longer than the standard length, or the collar is less than $\frac{5}{16}$ in. thick, the axle shall be considered as scrap and so credited.

Rusted journals awaiting application to equipment may be cleaned off with sand paper; a file or emery paper should not be used. Journals should be calipered to see if they are worn hollow or tapered, also, if desired, a steel straight edge may be employed. If the difference between the diameter of the same journal measured at any two points is $\frac{1}{32}$ in. or more the journal must be turned.

Axles must be closely inspected for seams, cracks or flaws. Seamy journals may be returned to service if the seams can be removed by turning within the required limits. Cracked or flawed axles should be tested by painting the doubtful parts with white lead paint, and then holding a flatter on the end of the journal and striking it with a sledge; oil working through the paint will indicate flaws. Axles exhibiting cracks or flaws, or showing signs of excessive overheating or below limits in any respect, must be scrapped. Brake rods and brake chains riding on axles must be avoided.

Defects of Wheels

Wheels are not generally safe for movement with the following defects: Slid flat cast iron, cast steel, wrought steel or steel tired wheels, if the flat spots are more than $2\frac{1}{2}$ in. in length, or, if there are two or more adjoining spots each 2 in. or over in length.

Shelled out: wheels with defective treads on account of cracks or shelled-out spots $2\frac{1}{2}$ in. or over, or so numerous as to endanger the safety of the wheel.

Brake burn: wheels having defective treads on account of cracks or shelling out due to heating.

When the worn spot is $2\frac{1}{2}$ in. or over in length. Care must be taken to distinguish this defect from flat spots caused by sliding wheels.

Seams—Seams in wheels $\frac{1}{2}$ in. long or over at a distance of $\frac{1}{2}$ in. or less from the throat of the flange, or seams three or more inches long, if such seams are within the limits of $3\frac{1}{4}$ in. from the throat of the flange on the tread of the wheel.

Broken or Chipped Rim or Tread—Broken or chipped rim or tread, if the tread measured from the flange at a point $\frac{5}{8}$ in. above the rim or tread is less than $3\frac{3}{4}$ in. in width, or if the bearing face of the tread or rim which may engage the top and exposed face of the rail is more than $3\frac{1}{4}$ in. wide.

Cracked or Broken Flange or Chipped Flange—Cracked or broken flange, or chipped flange, if it exceeds $1\frac{1}{2}$ in. in length and $\frac{1}{2}$ in. in width.

Wheel Loose or Out of Gage—Wheels are out of gage if less than 5 ft. 4 in. over the outside edges of the rim or 4 ft. $5\frac{1}{4}$ in. between the inside edges of the rim.

Worn Flanges—Cast iron or cast steel wheels under cars of less than 80,000 lb. capacity, with flanges having flat vertical surfaces extending 1 in. or more from the tread, or flanges $15/16$ in. thick or less, gaged at a point $\frac{3}{8}$ in. above the tread. Wheels under cars of 80,000 lb. capacity or over, with flanges having flat vertical surfaces extending $\frac{7}{8}$ in. or more from the tread, or flanges 1 in. thick or less, gaged at a point $\frac{3}{8}$ in. above the tread. In the case of wrought steel or steel tired wheels, flanges having flat vertical surfaces extending 1 in. or more from the tread, or flanges $15/16$ in. thick or less.

Bursting Wheels—If the wheel is cracked from the wheel fit, outward by pressure from the axle it should be immediately removed from service.

Type of Wheel to Be Used—Cars intended to be equipped with wrought-steel, cast steel or steel tired wheels, and so stenciled, if found with cast iron wheels, must be changed to the proper standard and at junction points particular care must be used by inspectors on equipment coming from connections and proper record and billing made.

Tread Worn Hollow—Tread worn hollow $\frac{3}{8}$ in. or more for a distance of 3 in. is not safe to run and the wheel should be removed from service.

Speaking in a general way regarding the various defects, especially those encountered in connection with cast iron wheels, the following comments are made as information: So far as flat sliding is concerned, the particular point to be noted in cast iron wheels is that the length of the flat spot is generally definite in appearance: the borders of the flat spot are clearly defined and are not pounded out in service, but a characteristic noise is produced which is well recognized and which calls for removal of the wheel under certain conditions. The intensity of the blow on the rail for a flat spot up to $2\frac{1}{2}$ in. long is not very great. The severity of the blow increases as the spot increases, until a maximum is reached at a certain speed, after which a decrease is shown. The critical speed is dependent upon the length of the flat spot. The longer the spot, the higher the speed at which the maximum blow is delivered. Conditions in a steel wheel are somewhat different because of the quality of the material which allows the boundary of the flat spot to be pounded out and lengthened until finally an eccentric wheel is produced instead of the short restricted spot as in the case of the chilled iron wheel. The long rounded spots do not produce a distinctive noise, and, therefore, are not noticed and often wheels remain in service until a very considerable eccentricity is developed, constituting a serious element of danger, especially in cold weather when the track is ice-bound. The only chance for a chilled iron wheel to develop eccentricity is when worn through the chill. The causes for flat spots in the chilled iron wheel are numerous, and if careful attention is given this matter a very material reduction in their number can be secured. It is generally known that from two to three times as many flat spots develop in the winter months as during the summer months in the colder climates.

The next item of great importance is the subject of broken flanges. The office of the flange is to direct the truck, and, therefore, one flange or the other is in almost constant contact with the rail and subject to rubbing or grinding under considerable pressure. This is especially true when traversing a curve where the flange pressure amounts to 10,000 to 20,000 lb. under ordinary operating conditions and impacts may, of course, momentarily double these amounts. This continuous grinding in the absence of lubrication, results in flange wear.

Seamy wheels, or a seam in the throat, is responsible for a considerable number of broken flanges. There are two classes of seams, one of which develops below the surface of the metal and is known as a blue fracture; the second occurring in wheels of low chill, which is of a progressive

type, starting in small cracks in the throat which eventually unite into a line representing a crack through the chill, which may progress through the grey iron and result in a broken flange. This type of seam can be eliminated by avoiding extremely low chill in the manufacture of wheels. The blue fracture cannot be detected until the surface metal (usually about $\frac{1}{8}$ in. thick), is broken through, disclosing the seam below. This type is a foundry defect and can be avoided by pouring iron of the proper temperature in casting the wheel. The cause for these seams, as already stated, is that the iron when poured into the mold first fills the lower part of the hub and then travels through the bottom plate and brackets, filling up the flange. The section of the mold forming the flange is thin and the upper part is formed by the metal chiller. It will be readily seen that the metal in the flange would be cooled somewhat by passing over the cold sand of the mold and coming in contact with the chiller. This metal is also not stirred or mixed by the subsequent metal entering the mold, as it flows on top of that which forms the flange. It is evident that the metal in the flange has already set solid and has started to contract, while the metal above the throat is still in a pasty condition, with the exception of a thin layer of surface metal which was quickly cooled by contact with the chiller. The more rapid cooling and contraction of the metal in the flange, as compared with that of the tread, tends to cause a separation, or seam. This is only true, however, where the iron when poured was not of a sufficiently high temperature to set homogeneously throughout the tread and flange section.

Brake Burning—The question of brake burnt wheels has already been mentioned. In brake burnt wheels, the tread is broken up in fine hair lines running parallel to each other across the tread of the wheel, generally covering a considerable portion of the circumference.

In extreme cases the cracks may open considerably, even though no metal is broken away; this is brought about by the rapid heating and cooling of the tread over the area covered by the brake shoe.

In freight service brake burnt wheels are developed in great numbers in sections of the country where heavy grades are most frequent and where the tonnage per effective brake is greatest. On heavy grades the brakes are applied to control the speed and therefore the action may be prolonged indefinitely. Under such conditions there is very little danger of sliding the wheels, hence the entire circumference becomes intensely heated, and when the heat becomes excessive and is generated in a sufficiently short period of time, it will cause the metal to break up into fine heat cracks, which have already been described.

In most trains there are a number of cars in which the brakes are ineffective or cut-out. The effect of this is to increase the tonnage to be controlled by the remaining cars having effective brakes, and even under these unfavorable conditions there is not much danger of burning the treads of the wheels if the brake shoes are in proper position; but for various reasons the brake beam is not always central and one shoe may overlap the rim while the other crowds the flange.

The pressure on the shoe is not changed on account of its position, hence, when the bearing area is reduced the pressure and the resulting heat per square inch are increased in the same proportion as the bearing area is decreased. This accounts for the number of brake burnt rims and also for cracked flanges when the shoe bears heavily on the flange.

This condition is also quite likely to crack the plate of the wheel on account of the expansion at the rim while the tread of the wheel near the flange is cold, which produces a strong leverage, throwing the front plate into tension to such an extent as to sometimes cause the metal of the front plate to fracture for a distance long enough to reduce the pressure.

When a chilled iron wheel has become brake burnt and is kept in service, the subsequent pounding disintegrates the metal which drops out little by little and results in a condition called "comby from brake burn." This leaves the metal in a ragged condition, as the plane of cleavage is radial or perpendicular to the tread, and small particles of metal break off more or less irregularly.

In this connection, it is well to mention slid burnt wheels. When a wheel slides, an intense heat is generated almost instantaneously, and the metal is rapidly worn away, leaving a flat spot, often showing a fine network of hair cracks around the area of the flattened surface. This condition usually appears in spots about two inches long, either singly or at various parts of the same wheel. If the slid flat spot is not large enough to require removal and the wheel remains in service, the metal which has been disintegrated by the heat may break up and drop out, resulting in a condition known as "comby from sliding."

Shelled Out Wheels—The term "shelled out" refers to spots on the wheel where the metal has dropped out from the tread in such a way that a raised spot is left in the center, with a cavity more or less circular around it. In this case, in addition to the radial lines of cleavage, there appears a holding element of the particles making the wheel parallel to the surface of the tread, and, therefore, the bottom of the defect is more or less smooth, somewhat resembling an oyster shell.

The cause of shell outs does not seem to be as self-evident as that of comby wheels. The conditions which exist and give rise to shell outs will, therefore, be described in detail. The maximum air brake pressure is adjusted for the light weight of the car, hence wheels are not as likely to slide under loaded cars. Sliding often occurs just before a train comes to a standstill. This is occasioned by the greater efficiency of the brake shoe as the speed of the train decreases. The greatest frictional resistance between the wheel and the brake shoe occurs just as the wheel is about to stop revolving and often at this point exceeds the frictional resistance between the wheel and rail, in which case the wheel begins to slide. After the wheel once begins to slide, the friction between the wheel and the rail is very much lessened and sliding will continue until the brake pressure is reduced.

When the sliding is over a distance of only a few feet before the car comes to rest, the term "skidding" is applied and a small skidded spot the size of the area of the wheel in contact with the rail is produced. A flat spot no larger than the contact area shown is not sufficient to cause the removal of the wheel, but the subsequent blows received in regular service very often result in the metal breaking or shelling cut around the surface of this contact area, forming a shelled out spot.

During the time the wheel is sliding, all the mechanical energy represented in the resistance to motion is transferred into heat through the agency of friction; and as mechanical energy and heat are mutually convertible, the exact amount of heat generated can be easily calculated and it is a matter of common observation that often the melting point is reached.

Cracked Plates—The question of cracked plates is another matter deserving serious attention. The primary cause of cracked plate wheels is an expansion stress, due to sudden heating of the tread while the plates are cold. When the brakes are applied continuously, a rapid expansion takes place in the metal of the tread which produces a strong tensile stress on the plates. Usually the heating is more severe toward the rim, and, therefore, there is a greater stress on the front plate than on the back plate.

In addition to the temperature stresses, the flange pressure reacts on the plates, producing a tensile or pulling stress on the front plate, and a compression on the back plate, hence the combination of stresses on the back plate

tends to equalize each other. Too much care cannot be exercised by inspectors to locate cracked plate wheels, as they are a source of tremendous danger in service.

Worn Through Chill—The defect known as worn through chill cannot often be discerned by the appearance of the tread and manner in which it is worn. If worn irregularly, that is, deeper at some places than at others, or if worn flat, it is evident that it has worn through the chill. Wheels seldom wear through the chill all around the tread at the same time; therefore, when a wheel is worn evenly, no matter how deeply, or shows the shape of the rail all the way around (commonly termed "railworm"), and has no appearance of being worn flat at any place, there is a good reason to question whether it has worn through the chill. This can be determined by polishing the tread with emery cloth, breaking off the flange with a sledge, denting the tread with a chisel, or breaking the wheel. When the first method is used, if a few small black dots of graphite can be seen, the wheel is just starting to wear through the chill. If the graphite shows plainly, it is well worn through the chill.

A method in vogue with some railroads is to dent the tread with a chisel, and if the chisel makes a deep mark without blunting its edge, the wheel undoubtedly is worn through the chill.

Tread Worn Hollow—The amount a wheel shall be worn in the tread to warrant its removal from service is left largely to the judgment of the car inspector. The idea is that wheels should be removed when worn sufficiently to permit the rim to project far enough below the top of the rail to render it liable to breakage when passing over frogs, or when the flange becomes so high that its end is likely to strike the bottom of flange ways. When wheels are worn excessively hollow, damage is done to the track at frogs and crossings on account of the overhanging rims and the high flange, which causes excessive pounding, resulting in rapid deterioration of the track at these points and often breaking off track bolts. It is the practice in track work to allow a minimum of $\frac{5}{8}$ in. for flange clearance at the bottom of flange-ways in frogs, crossings, guard rails, etc. This allows for the tread to wear down $\frac{5}{8}$ in. before the flange would strike the frog and crossing fillings on new rails. It is customary in the heavier rail sections to allow more than $\frac{5}{8}$ in. below the end of the flange. This is a matter which needs attention locally to meet the daily requirements of service.

The minimum amount a wheel shall be worn hollow is not specified for freight service, but is generally conceded to be $\frac{3}{16}$ in. Some railroads recommend that wheels be allowed to wear down $\frac{3}{8}$ in. before condemning them, unless worn through the chill.

Worn hollow is the legitimate condition of worn out wheels. In the lighter capacity cars, the percentage of wheels removed for this cause is large, while in the heavier capacity cars flange wear is greater and also all of the heat defects are in greater evidence, hence the percentage of worn tread wheels is reduced. Wheels which crowd the rail on one side or the other should be very carefully observed. Complete sets of suitable wheel gages with complete instructions are sent to any station on the system making request for them.

Guarantee on Cast Iron Wheels—It is occasionally necessary to purchase wheels from outside concerns. This material is purchased under the guarantee shown in the table below, and where renewals are made within the period

stated due to manufacturer's responsibility, claim must be made for replacement, all cases being fully written up to the master car builder and the wheels held for disposition. Wheels manufactured in the railroad company's foundry must be checked up just as severely and any failure in service reported in the same way and the wheels held for examination.

Wheels which fail to render this service on account of any defects in material or workmanship will be replaced free of cost to the railroad upon delivery of the defective wheels at the works. The wheel makers do not replace wheels which fail to render the guaranteed service on account of flange wear nor wheels removed *in pairs* on account of shelling out.

AN INTERESTING CHAPTER FROM AMERICAN RAILROAD HISTORY

"The Portable Boats of Early Railroad Practice" is the title of an article written by J. Snowden Bell and recently published by the Baldwin Locomotive Works in the form of a booklet included in the Records of Recent Construction (No. 97). The book describes what in the 30's was referred to as "the great transportation system" extending from Philadelphia to Harrisburg. This was principally a canal route connected by stretches of railway for which Mathias Baldwin constructed the early locomotives, and which later was absorbed by what is now the Pennsylvania railroad. The first pages relate the entertaining narrative of a pioneer who crossed the Alleghenys with the first portable boat and made his way down to the headwaters of the Mississippi. This boat was not designed as a portable affair, but was intended to be sold on his trip west when he reached the point at the foot of the mountains where rail transportation replaced the canal barge. It was found practicable, however, to cut the boat in sections, load it onto flat cars, and thus transport it over the mountains. This led to the construction of many sectional boats, the details of which, together with the cars specially constructed for this service, are well described and illustrated with some of the very early patent drawings covering these conveyances.

The Baldwin Locomotive Works deserve credit for giving wider circulation to a phase of American Railroad history that is fast slipping into obscurity, and are fortunate in securing the authorship of Mr. J. Snowden Bell. It is hoped the publication of this fascinating page from early American history will lead to greater publicity concerning American railroads in the making.

COST ACCOUNTING—THE KEY TO COST CONTROL

A Discussion of the Advantages of Cost Keeping with a Description of a Typical System

BY GEORGE W. ARMSTRONG

CONTROL of industrial operation requires a panorama, a perspective bird's-eye view of the multitudinous activities of that industry. Effective control requires more, it requires an intricate, digested knowledge of the details of those activities; requires a knowledge as to the equivalency of return for expenditures to successfully avoid the wastes which cannot otherwise be detected.

Railroad accounting is clearly defined by Interstate Commerce Commission regulations. This uniform classification of accounting, aside from any inherent merits or defects, serves the purpose for which it was designed. It furnishes, indeed, statistical data of the most valuable kind for the railroad executive in charge of the property, for the investor and for the regulating commissions. But the reports of railroad operation as a whole fail to throw light on the details of its productive activities.

Cost accounting is concerned with the details of these primary accounts in railroad operation. One of the prime functions of cost accounting is to enable the executive in immediate charge to know details promptly. Records of cost by themselves do not effect economy, it is only by their proper presentation in convenient and convincing form to the executives responsible, that these executives can correct inefficiencies, pointed out by these records, through improvement in organization, administration and in individual processes and methods. The degree of refinement in a cost accounting system should not exceed that required to secure this result, i. e., effective control. The essentials of any cost keeping system are:

That it accurately account for materials and supplies purchased and given out.

That it charge labor to the work on which it is employed.

That it furnish an accurate check and distribution of overhead expenses or burden.

That it record facts and conditions and provide for current interpretation of their significance.

This discussion will be confined to the Maintenance of Equipment but it is not inapplicable to the other branches of railroad operation. The Interstate Commerce Commission Statistics of Class I railroads for the year ending June 30, 1916 indicate the expenses for Maintenance of Equipment to bear the following ratios to total operating expenses:

Maintenance of Equipment—Steam locomotive repairs, 8.017 per cent; freight train car repairs, 8.18 per cent; passenger train repairs, 1.563 per cent; total, 17.760 per cent.

Transportation—Engine house expense—yard locomotives, .506 per cent; train locomotives, 1.642 per cent; total, 2.148 per cent. Aggregate total, 19.908 per cent.

The summary of statistics for Class I railroads as issued by the Interstate Commerce Commission to December 31, 1918, shows that the percentage of operating expense applied to maintenance of equipment in 1918 was 27.73 per cent instead of 17.76 per cent as given above for the year ending June 30, 1916. The details of division to steam locomotives, freight train and passenger train car repairs, and for engine house expenses were not available, but the increasing magnitude of this branch of operating expenses can be visualized by the comparison.

The Function of Cost Accounting

Cost accounting with respect to these operating expenses should embrace sufficient detail to reflect accurately the distribution of expenditures, to insure quick analysis of details and furnish cost data for expert analysis as close as possible

in point of time to the occurrence of the charge. Close relation between responsibility and cost is the active agency required for improving operation. Refinement of detail beyond what is necessary to provide data for effective control is not justified, but the absolutely necessary cost of control, whatever it may be, is worth the cost.

Results will not be secured from cost knowledge if confined solely to afterthought analysis. The cost agency should also embrace means to predict in advance results with respect to new needs based on past performances. Otherwise it will be impossible to avoid excessive expenditures in many instances for articles which can be more cheaply purchased. On a large trunk railroad recently, the need developed for a rather large number of pieces of a certain forging on Mikado type locomotives. An initial lot was made under the steam hammer, machined and applied. Analysis then developed that these parts cost from two to three times more for labor and material alone than better drop forged parts that could be purchased in the open market. Advance cost analysis would have determined this without the loss incurred in this instance. Similar examples can be duplicated daily in our railroad shop operation.

Cost accounting is needed in railroad operation today as never before. The prices of materials have increased, labor has doubled in cost, productive efficiency has lessened. The times demand that the trained finger of management maintain unbroken contact with the pulse of production.

Disproportionate relations existing between the labor and material components of shop operations compared with those existing in pre-war times may necessitate modifications in practices. Where under former conditions things could be produced economically, purchase may now be cheaper. Machine tools and shop facilities at one time adequate may have become utterly inadequate viewed in the light of present wages and restricted production. How can these questions be settled without the aid of an efficient cost accounting system?

Proving Economies

The superintendent of motive power of a large trunk line recently stated: "I am almost convinced that we should make everything possible for locomotive repairs at a central point, where we can install the best facilities and get the benefit of quantity production. Then we should make our repair shops simply dismantling and assembling shops, doing only what other work is necessary to repair worn parts." How are the roads to determine whether that should be their goal in the future, and whether it is productive of economies predicted, if not given the aid of an efficient cost accounting system?

It has been said figures do not lie. The corollary to this is that a true interpretation depends on accurate analysis. And if figures sometimes lie, they also talk. Many conditions are tolerated, inadequate and woefully inefficient facilities are maintained, practices are perpetuated because figures are not given their opportunity to talk. Cost knowledge is lacking to discern which is unprofitable, cost knowledge is not at hand to drive home to the railroad executive the true economy of improving conditions, facilities and practices.

E. J. Pearson, former Federal Manager, now President of the N. Y. N. H. & H. in the discussion of Mr. McManamy's

paper before the New England Railroad Club said: "There is no executive and no board of directors that knows about your old lathe . . . why at the Southville roundhouse . . . engines are being delayed and traffic is not handled, although they may know that traffic is not moving as it should. They don't know the particulars of your needs unless those who are on the firing line put the case in shape and submit it, and do it so concisely, clearly and effectively that it will compel consideration on its own merits.

"Every one financially interested in a railroad is interested in the service, but particularly in the dollars and cents that are left at the end of the month. . . .

"If improvements are advantageous and hence money makers, the cheapest thing that any railroad can do is to make them. If there is some improvement that will pay twenty-five per cent on its cost and money is worth six per cent, there is nineteen per cent of velvet right there. . . .

"I agree that improvements recommended by Mr. McManamy aggregate big if you get the right ones. There are many of these projects that are presented simply because they are a good thing and when analyzed are explained as being desirable, that somebody else has them, that they are modern, or for reasons equally intangible. Bankers do not finance on statements of that character, but they do understand clear, concise statements that prove you can make nineteen per cent velvet as a result of the undertaking. . . .

"The point I desire to bring home to all is the necessity of working out your case, proving it and of then presenting it understandingly. Reduce your proposition to the absolute necessity, the benefits, the savings and the advantages and put it in shape so that when it comes up to those who do not know the details of the mechanical business, but do understand net returns, and on whom in the final analysis we must depend to finance these needs, the situation is made clear to them."

A Plan of Cost Accounting Discussed

Bearing in mind the essentials of cost accounting and its crying need, it would be well to consider its method of accomplishment. The first question to be answered in determining upon a system is: What is cost accounting expected to accomplish on a railroad? Is it to secure a record of the exact cost of each shop operation, or to furnish an aid to production and a means of determining whether an equivalent return is secured for value expended? Obtaining a complete distribution of the time consumed by each workman on each operation will not solve the cost problem, but will result, the more complete and elaborate such distribution is, in getting further from the desired result. The only result will be a tremendous volume of detailed information practically impossible of digestion. This will neither serve as an aid to production nor a measure of equivalency.

Shop Distribution

The output unit for locomotive shop operation is the locomotive, but this for purposes of cost accounting is as much too unwieldy as the detailed distribution is too elaborate. For constructive analysis in directing operation, controlling and determining policies based on cost accounting facts, and for finding whether a proper equivalent is secured for money expended, labor and material distribution should be made to master classifications of work by key reference and locomotive number. A standard key, either using a mnemonic or figure reference used as a prefix to the locomotive number should be established. Provision should be made for checking labor distribution directly in the department and without imposing an additional burden on the foreman. Material orders should be issued by one or more men delegated primarily for that duty, thus insuring proper distribution as well as a check on the disbursement of material. The suggested divisions of charges would be

Engine Trucks.	Driving Boxes.
Cylinders and Guides.	Spring Riggings.
Pistons, Piston Rods and Cross-heads.	Wheels.
Valves.	Trailer Trucks.
Valve Gear.	Rods.
Power Reverse Gear.	Steam Pipes.
Front End.	Air Brake Work.
Flues.	Cabs.
Frames.	Cab Fittings.
Lubricators.	Stoker.
Injectors.	Superheater.
Electric Headlight.	Brick Arch.
Boiler.	Tender Frame.
Fire Box.	Tank.
Grates.	Tender Trucks.
Ash pans.	Draft Gear.

Given such a distribution of charges, a standard can be established based on experience which will serve as a measure of equivalency without the recording of details. However, sufficient detail should be recorded as to operations, so that the data can be employed at a future date for compiling unusual cost data or checking marked variations. As an aid to production, working on a day work basis, details of operations together with time consumed should be recorded only if currently associated with a standard time basis of comparison. The record of efficiency thus furnished will only be of value if followed up close to the event.

In many shops, labor conditions, aside from the additional factor of the expense and waste of time, will demand that records be secured with the least disturbance of shop management. The simple, sensible way to handle labor costs is that advocated by G. Charter Harrison,* i. e., "to set time standards for each operation and instead of recording the time spent by an operator on every job he performs during the day to compare his total time for the day with his production figured in terms of standard time. Under such a method all that is required in the form of time clocks is a regular in-an-out clock recording the actual time spent on the premises, and a record of the work which the man produces."

The accounting for the material used should follow closely the same lines as the distribution of labor charges. It should do more, however; it should involve the installation of a perpetual inventory system for handling storehouse material, which should be accurately checked at intervals with actual storehouse stock. Adjustments in storehouse balances should be made systematically throughout the year, instead of at the time of a fiscal annual inventory. Care should be taken to keep adjustments to a minimum, accounting as accurately as possible for disbursements currently.

Distributing Overhead

A separate account should be opened in the shop expense ledger for the indirect expense in each department, leaving only that portion of the indirect expense impossible to definitely locate to be generally applied upon the whole labor payroll of the shop. This results in an accurate check and distribution of the overhead, and is an effective means of minimizing indirect expenses. The indirect expense thus allocated to a department should be applied to the direct labor of that department.

Effective control is insured by definitely allocating expense by fixing responsibility along department lines. This fixes individual responsibility and gives the department executive the means of telling whether his costs are high or low, as his labor cost is forecast by the group distributions.

All distribution of labor should be made daily, by departments and distribution balanced with the labor payroll of the department. Material distribution can be cared for at less infrequent intervals.

Engine House Distribution

The problem of accounting for engine house expenses is a different problem from that of shop operation. The ideal possibly would be allocating of expense pertaining to each

*Industrial Management, Jan., 1920, p. 13.

individual engine for purposes of comparison as between classes of equipment and determining the particular engine of a class which is disproportionately expensive because of some fault in repair or construction. However, dependable figures as to individual engines cannot be secured except at a cost not warranted by the value of the results. It would require a force at each terminal to check each workman on and off each job, and it would not serve any more useful purpose than could be accomplished in a simpler way.

Engine house expense should be distributed as to labor and material to major divisions of maintenance work, in addition to the terminal operations, for example:

- | | |
|-----------------|-----------------|
| Front Ends. | Spring Rigging. |
| Cylinders. | Wheels. |
| Valves. | Cab Work. |
| Valve Gears. | Stoker. |
| Air Brake Work. | Superheaters. |
| Rods. | Tanks. |
| Boiler. | Brick Arches. |

Subdivisions as refined as those employed in shop operation are not required but sufficient subdivisions should be made to give useful checking groups as between terminals as well as judging the efficiency of the particular terminal at any time. These subdivisions would follow closely the

assignment of workmen, and so would involve a minimum possibility for error, even if the workman was depended upon for time-card distribution.

An approximately accurate analysis of costs for different classes of power could be secured from these subdivided

costs by equating them on the tractive power mile basis or ton mile basis for the division.

Having considered the abstract needs for cost accounting, and a theory as to application, it might in conclusion be interesting to analyze a system embodying many of the essential features which is in actual use on the Baltimore and Ohio Railroad at their Mont Clare, Baltimore, Md., shops.

Cost Accounting Concretely Applied

This description relates to the shop order system used for following all foundry, forge shop, spring shop and manu-

Work Order for Individual Departments

facturing machine shop work, in fact everything except the work directly applied to the dismantling and repair of locomotives and cars, which is charged in total to individual locomotives, and passenger train and freight train car repairs, which are handled in the usual manner. A great portion of the material required for locomotive and car repairs, however, is finished for stock and consequently represents a material charge, reducing to a minimum the labor charge distributed as a blanket charge to locomotive, passenger or freight car repairs.

Shop Order Department

All individual shop orders are originated in the storekeepers' office on form 2426, original and duplicate, and

sent to the office of the assistant to the shop superintendent who is in charge of the shop order office. Monthly shop orders are used for certain regular work, i. e., brass foundry, iron foundry, spring repairs other than locomotives undergoing repairs at the shop, bolt forgings, steel car repair parts flanged, shop machinery and tools, etc. For these classes of work a regular shop order number is definitely

countant's office, properly marked, denoting the closing of the shop order.

When form 2426 is received, form 1059-C is made out to the foremen of the various departments. This card gives all

Master Record Card

fixed, which in reality becomes an account number. The shop order number assigned by the storekeeper is keyed to denote the month in which it is issued. This is denoted by the ten thousand group in which the number occurs, thus 10,067 is a shop order issued in January, 30,152 a March shop order, and so on.

On receipt of the material request form 2426 by the shop

information necessary to finish and deliver the work. In the event of several departments being involved, each foreman receives a copy marked over "foreman," original or

Form for Transfer of Material

number, quantity order, date issued and requisition number is entered on the master record card, form 2435-B.

After the receipt of form 1059-C, as the foreman requires material for the finishing of the shop order he issues form 1124-B on the shop order department, which then originate form 2311 on the storehouse and material is delivered by motor truck dispatch. A record is kept on a mimeographed form of shop order material distribution sheet assigning a serial number with suffix number for each material order issued. Thus is insured an accurate account of all material used in completing the shop order, as well as giving the accounting bureau a check, because if the last material order received bears suffix 20 and numbers 12 and 16 are missing they must be looked up before the shop order is closed.

In connection with the use of form 2311 it is interesting to know that these are safeguarded as if they were checks

payable to the bearer. The number stamped at the top of form 2311 in the general foreman's office identifies the issuing foreman to whom this number is assigned. The signature used in conjunction with the identifying number must correspond with the authorized signature filed in the storehouse.

Each transfer of material from one department to another, or to the storehouse is made by means of form 1061, which must accompany each transfer and be signed in the department receiving the material, returned to the issuing department and sent from there to the shop order department. When form 1061 is received for finished material delivered to the storehouse, it is immediately recorded on the master card form 2435-B. In this way, the shop order department is continually appraised of the status of all shop orders relative to material ordered for work in progress, the status and location of work in progress and the amount of work completed to date. The foreman also keeps a daily record

Foundry Master Record

on the back of form 1059-C, so that he is also in possession of information showing the status of the shop order, until it is completed when he returns it to the shop order department signed and dated.

Forgings and foundry output are handled on monthly shop orders as previously indicated. Forgings, bolts, springs and steel car parts are ordered by the storehouse twice a month, special stock oftener. As soon as the order is received it is entered on master card form 1059-A and form 1059-B issued to the foreman. A serial number is stamped on the end of form 1059-A used for filing and ready ref-

erence. This serial number also appears on form 1059-B and form 1061, as issued.

The foundry work is also handled on permanent yearly shop orders. Each morning the storehouse advises the shop order office of castings required. Immediately form 1085 is issued on the foundry and also entered on the foundry master card. A copy of form 1085 is also kept on file in the

Work Order for Monthly Shop Orders

shop order office for convenient ready reference. These cards are kept filed by weeks and unfilled cards are set back each week, so that not only do they serve the purpose of showing what is due, but also how long due. This aids in expediting the oldest orders.

The foundry is the only department where form 1061 is not used, the record of work completed here being taken from the inspector's daily record of castings delivered to the storehouse casting platform.

Accounting Department

When form 2426 is received by the accounting department, a master record card form 1195 is made out indicating not only the essential material references but also the department references.

Each day's labor distribution is taken from the service cards form 2453 Rev. being entered by departments onto mimeographed distribution sheets. As the distribution is taken off, the service card number is noted as well as the

hours and amount. Each distribution sheet is then balanced against the total hours and the amounts extended noted in pencil on the top of the service cards. Of course, it is often impossible to secure an absolute balance but the variation is kept to a minimum. The daily distributed labor charges are then entered on form 1195 back under the respective de-

on the respective master record cards form 1195 before filing.

At the end of each month the shop expense (denoted ME) is figured and entered on the card form 1195. This is determined by taking the prorated total of unclassified shop expenses based on the previous month's labor charge for maintenance of equipment and shop orders to fix their respective divisions of the shop expense. The proportionate shop expense thus arrived at is distributed on the basis of the actual labor charge in the proper month.

Twice during the month and at the end of the month, a list of individual shop orders closed is sent to the storekeeper giving quantities, description of material and charge. All unfinished shop orders are balanced and totaled at the end of the month for clearing on the shop report.

The experience of this one road bears out the belief that cost knowledge is essential to control shop operation. The total of \$1,094,825,873 for maintenance of equipment expenses for the Class I railroad during the year ending December 31, 1918, emphasizes the possibilities of even slight improvements, 1 per cent saving being \$10,948,258. Cost knowledge which can only come through cost accounting and cost analysis is one of the most important agencies

road operation is due to the same cause? An awakened cost consciousness on the part of management is the one great hope for bettered operation; for that awakening will lead straight and inevitably to improved facilities, organization and equipment.

AMERICAN WELDING SOCIETY HOLDS FIRST ANNUAL MEETING

The American Welding Society held its first annual convention in the Engineering Societies Building, 33 West 39th street, New York, on Thursday, April 22. The morning session was devoted to society business and announcement was made of the election of officers. J. H. Deppler was elected president, J. W. Owens was elected vice-president for two years, and D. B. Rushmore was elected vice-president for one year.

A plan of action for the American Bureau of Welding for the coming year was discussed at the afternoon session. It was proposed to reduce the representation of the American Welding Society in the American Bureau of Welding. A committee was authorized to lay down a scheme of organization and to prepare a program for the coming year.

Comfort A. Adams, chairman of the bureau, spoke briefly on the subject of welded joints for pressure vessels. A point of particular interest was brought out in this in connection concerning the use of different kinds of welding machines. Mr. Adams showed that within the limits of arc length consistent with good practice in electric welding, it made no difference whether the machine used was a constant current, constant heat or constant unit heat machine.

Mr. Adams' statement was in effect as follows: In the case of the constant heat machine the current is decreased as the arc is lengthened. The constant current machine maintains a constant current for any length of arc within the limits of the machine. In the case of the constant unit heat machine the current increases as the arc is lengthened. Owing to the fact that the arc spreads out and covers a greater area as it is lengthened it is necessary to increase the current to maintain a constant heat per unit area. Theoretically this would be the ideal machine, but within the limits of arc length consistent with good practice, the variation of current is practically a negligible quantity.

The objective of the bureau's activities will be to determine how a good weld can be assured. Methods will be sought for testing the quality of a weld after it is made and for determining the best way of eliminating locked up stresses in long welds. At present the greatest hope lies in controlling the conditions under which the work is done. This will greatly reduce the amount of nitrogen in the weld. Heat treatment is beneficial in that it tends to break up the combined nitrogen.

The afternoon session was concluded by an announcement that a number of manufacturing companies have offered to assist the bureau with its research work. Much of this work is in a partially finished condition.

Speed of Metal Arc Welding

At the evening session, three papers were presented and discussed. The first paper presented was "The Speed of Metal Arc Welding," by William Spraragen, of the department of electrical engineering of the University of Washington. On account of the absence of Mr. Spraragen, who had been called away to the Pacific coast, the paper was read by E. A. Miller. In substance the more important portions of the paper are covered in the following statements:

The welding operator is a most important factor in successful arc welding and, of course, the more skillful the operator the more and the better work will be turned out. It is very desirable to be able to compute the rate at which arc welding may be accomplished, but the complexity of the different elements entering into it are such that it is very difficult to calculate the time required to produce certain kinds of joints. For inside work, 1.8 lb. of metal deposited per hour is a reasonable estimate, but when the work is performed outdoors there appears to be a reduction in the amount of metal deposited so that the average appears to be

1.2 lb. of metal deposited per hour for outdoor work. This reduction in the amount of metal deposited is probably due to the cooling action of the air.

With reference to the type of welding apparatus used, whether it be alternating current apparatus or direct current apparatus, it is estimated that where first class welding operators are employed there is no difference in the speed between the two kinds of equipment.

In a few words of explanation the retiring president, Comfort A. Adams, explained that the paper on the speed of arc welding was based upon conclusions arrived at by tests made by the General Electric Company in welding up some 10½ tons of welding material. This work was done just prior to the signing of the armistice and while the work had been cut up into coupons, ready for testing, the tests have not been made up to the present time.

Automatic Arc Welding

The second subject for the evening was "Automatic Arc Welding Machines," by H. L. Unland, of the Power & Mining Engineering Department of the General Electric Company. Mr. Unland stated that the automatic control of arc welding was not new. He said that the automatic arc welding machine had been developed for the reason that it was desirable in turning out large quantities of duplicate parts to make this operation as nearly mechanical as possible. As a precedent he mentioned that years ago the General Electric Company had developed a similar machine for a gas cutting process which was used in the making of small gears, wheels, etc. Operators, cutting by hand, frequently ran over the line; these factors influenced the company to take up the question of mechanical feed and a satisfactory cutting torch was eventually produced. At that time it was found that the gas consumption was reduced to one-third and that the speed was increased four or five times over hand work.

The development of the automatic arc welding machine is merely an extension of the same principles into another field and for sections that are being turned out continuously the mechanical feed is the proper thing to use. Mr. Unland described the General Electric machine and with the aid of numerous stereopticon slides explained very carefully the operation of the various circuits used in the control of the welding wire to the work.

Gas Cutting

The third paper on Recent Development in Gas Cutting, by Stuart Plumley, of the Davis Bourmonville Company, was not read, but Mr. Plumley spoke briefly of the more important developments. The most successful development has been the cutting of cast iron with the gas torch. Cutting cast iron is particularly difficult because the oxide of iron melts at a higher temperature than the iron itself. The cutting is now accomplished by preheating the oxygen.

It is so easy to break cast iron that gas cutting is not often desirable, but it can be used to excellent advantage for such operations as cutting a frozen blast furnace cap.

Discussion

The discussion brought out the fact that the rigid method was used for welding tanks with the automatic electric welding machine. The statement was made that locked-up stresses were greatly reduced by reason of the fact that the speed of welding was very high. It was further stated that alternating current cannot be adapted successfully to automatic welding as a sensitive variable speed motor is required for feeding the metal into the arc.

Training of welding operators with the alternating current arc was advocated on the ground that because the alternating current arc had to be held within closer limits, the welders trained to use the alternating arc make better operators than those who receive their initial training with the direct current arc.

ECONOMY AT STATIONARY BOILER PLANTS

Some Loose Practices Common to Railroad Boiler Plants and What May be Done to Correct Them

BY C. M. ROGERS*

Service Manager, Locomotive Firebox Company, Chicago

THE operation of stationary boiler plants has been brought under the scrutiny of government, owner and manager in the past few years on account of a sudden well-founded realization of plant inefficiency; that in their condition as found they represented a tremendous drain upon the treasury of the operating concern, and that in the main they have fallen behind other institutions in the swift race of progress. It was also realized that these conditions could be remedied by an expenditure of time or money, or both, that would be quickly repaid by the economy effected.

The boiler plant is a producer, and should be so considered. Experts working on shop management are interested in increasing shop output and reducing cost of manufacturing their product, money is freely spent in every way imaginable upon shop improvements and much time is devoted to the study of shop methods. Production is right next door to the manager of a manufacturing establishment and is the object of his closest attention. It haunts him. The production of power required to operate a shop is obscure. Usually power is obscurely transmitted to the shop. The boiler plant is nearly always placed in a location separate from the main shop. The manager usually is appointed to his position because of his knowledge of shop work, and these men have seldom had occasion to familiarize themselves with the construction, operation and output of a boiler plant. Because of this obscurity and the concentration upon shop output, stationary boiler plants, as a rule, have been permitted to worry along with little attention until they are almost exempt from consideration as producers and are classed as a necessary evil. From the standpoint of production, they have been separated from the work of the shops to which they deliver power. As a result of this attitude plants are usually found in poor physical condition and employees assigned to operate them are not trained to a very high degree unless they have sufficient initiative to inform themselves and thus advance the interest of the company by improving operation as far as possible through their own efforts.

This general attitude exists towards plants up to 1,000 boiler horsepower. In recent years boiler plants of great capacity, representing the investment of huge sums of money and requiring large expenditures for fuel and other supplies, are receiving the most minute attention to maintain them in the best condition and to operate them as economically as possible.

A stationary boiler plant is fundamentally designed to bring together air and fuel in such a manner as to create combustion, the heat from which is to be converted to power through the medium of water. In order to maintain combustion the application of the ingredients must be controlled. To control the air the boiler is surrounded by a casing such as a brick setting. The fuel is controlled by the operator, either by hand or by mechanical means. As control of the air supply is essential, it should be made absolute by having the setting air tight in every respect. Air should be admitted to the fire

principally through the grates, so that proper mixture of the ingredients may take place. After going to the expense of providing facilities for burning fuel it is folly to permit cold air to sweep through the chinks in a poorly maintained setting to reduce the temperature of the products of combustion, thereby losing heat that would otherwise be absorbed by water in the boiler. Admission of the proper proportion of air under the best conditions is very inaccurate, but when cold air is permitted to pass through the brick work and other crevices the resulting losses amount to a larger percentage.

Plants may be found today where the operator controls the supply of air by means of the ash pit doors alone, leaving the smokestack wide open to emit large quantities of heat. If corrected he states that with the ash pit doors closed there is no pull through the fire, consequently the heat will not be lost. At the same time his setting is without plastic cement, brick work is full of small cracks and the fire doors do not fit. The head of air produced by the difference between atmospheric pressure outside the setting and a partial vacuum inside causes cold air to stream through these openings, cooling the gases and carrying heat off through the stack. Firemen and others are familiar with the use of a damper in the stove pipe at home, and they realize that to leave the damper open at all times is a wasteful practice which is directly reflected in the amount of their fuel bills. A damper in the breeching or smokestack of a boiler plant performs the same function as the stove damper, but the men in charge fail to realize this fact and drift along sometimes for years baling in coal during periods of light as well as heavy load.

One can find many plants equipped with stack dampers, but the fireman doesn't know they exist, not to mention the fact he does not use them. There are stack dampers installed in such a manner that it is necessary to get a ladder to climb up on top of the setting in order to adjust them; then they are usually found to be inoperative. Damper operators should be simple, easy to operate, arranged for close adjustment and located at the position where the fireman works—at the fire door—so that he can make frequent adjustments to suit load, fuel and other conditions. The fireman should be shown that by utilizing the damper his labor is reduced and he saves on the fuel bill. When he once proves this fact to his own satisfaction he will use his mind to save his muscle and ever after will be a booster for any project intended to save coal.

As a rule firemen are too industrious. They shovel coal as a matter of dull habit and seem to be contented with handling large quantities of fuel, with no thought of the various methods of helping themselves by reducing the quantity.

Most plants have variable loads. Some of them are required to respond to quick changes of load in rapid succession. Others perform to their capacity during the day shift and are to a large extent relieved during the night shifts. Still others have the load reduced to such an extent during the night that fires may be banked. The writer has in mind a pair of hand-fired boilers totaling 400 hp., which were without stack dampers and were operated with the ash pit doors wide open at all times. Every afternoon at four o'clock the load is reduced about 75 per cent; but the ef-

* Mr. Rogers was formerly supervisor of stationary boiler plants on a western railroad.

forts of the fireman to keep up steam were reduced only about 15 per cent; the difference gives an idea of the amount of fuel being wasted. After dampers were installed a thorough demonstration of the possibilities of damper regulation of draft was made for the fireman on each shift and instructions given to follow this practice for a while to determine for themselves its value. Looking in on the fireman on duty at five o'clock one afternoon about a month later, both dampers were found in nearly closed position, the place cleaned up and the fireman spending most of his time lounging on a "lazy back" smoking a pipe. He was fully convinced that dampers were an improvement and was quite elated over the reduction in labor he had to perform. The CO₂ content of the flue gas at this time averaged 13½ per cent, which is a good figure for a plant of this kind.

If the damper is operated automatically by an effective appliance the very best results may be obtained. Such an operator should, if possible, be controlled by the pressure of air within the furnace, thus admitting only the required amount of air for proper combustion. An average of 15 per cent CO₂, representing perfect combustion, is possible with such an appliance.

The owner of a plant is under obligations to install suitable equipment and appliances if he expects his employees to become interested in economical operation, and once installed, co-operation should be expected of the men. The best way to get next to the men is to don the uniform of the fireroom and demonstrate the truth of your instruction by doing it yourself, if you can, to prove it. A supervisor wearing a white collar cannot overcome the deep-rooted though misplaced conceit of most firemen that they know all about the game. Actual demonstration of how the job should be done, reinforced at times by a little authority, will convince them nearly every time. There are some old timers who have followed the game too long in the same old way to change their habits. These men should be given less important work if they cannot progress.

The use of a portable gas analyzer will accomplish a great deal in educating firemen. By the use of this instrument the writer has convinced many firemen of the error of their methods. At the outset an explanation of how the instrument makes its simple analysis should be made; this arouses interest. A series of tests with the damper in various positions, with fuel bed in the same condition, indicates the kind of combustion they are getting. The important point is to find the position of the damper that will result in the highest percentage of CO₂ (carbon dioxide), at the same time maintaining the required steam pressure and avoiding excessive clinker adhesion to the grates. Using the boiler front or other convenient surface as a blackboard, the results should be chalked up for a lasting impression on those interested. If, with the damper wide open, analysis indicates a content of 6 per cent CO₂, the 17 per cent preventable waste of fuel should be shown, next the corresponding amount of coal in tons based upon the monthly consumption, and then the cost. If, with the damper partially closed, the CO₂ content of flue gas is raised to 11 per cent, the reduction of preventable waste to about 4 per cent should be noted, and if the plant can maintain working pressure with the damper closed to a position that will average 13 per cent CO₂, representing a preventable waste of 2 per cent, the firemen will properly be impressed, and by prolonging the test they will soon notice the effect upon the amount of labor they expend. If they fall into line they should be suitably commended.

Men who shovel coal as an occupation do not look upon fuel as a costly substance. They see it all day long day after day, ton after ton, until they have a subconscious idea that coal is the cheapest and most plentiful commodity in existence. There is need of disillusioning firemen on this point. The present cost of fuel requires the expenditure of time and money to save it.

A good gas analyzer may be depended upon to furnish accurate analysis of combustion conditions and serve to trace promptly the cause of preventable waste. Gas analyses, however, do not indicate boiler efficiency, which is affected by scale, soot and other factors. The CO₂ content of gases simply indicates the proportion of air and fuel in the products of combustion.

The accompanying chart illustrates one series of four gas analyses for each of three different boilers taken during a period of eight minutes between applications of coal, showing comparison between boilers equipped with automatically controlled damper, hand-controlled damper properly used, and boiler without damper. It will be noted the preventable waste of fuel due alone to improper combustion ranged from less than 1 per cent on the boiler with automatically-controlled damper to 14.5 per cent on the boiler without damper. Based upon a monthly consumption of 1,200 tons, this is equivalent to a loss of from 12 tons of coal per month on the one boiler to 174 tons on the other. These examples were taken at random from plants similar in size and are typical of results being obtained at many stations.

Effect on Flue Gas Analysis of Proper Use of Stack Damper

Curve No. 1 shows the percentage of CO₂ as analyzed from the gases taken from a boiler controlled by an automatically operated damper. It may be noted that one minute after fresh coal was applied to the fire, CO₂ was 15 per cent, and as this coal burned out, the percentage gradually reduced until at seven minutes the CO₂ was 13.3 per cent. The average CO₂ content for this curve is 14.3 per cent, or less than 1 per cent preventable waste of fuel.

Curve No. 2 indicates the trend of CO₂ readings for a like period on a boiler controlled by a damper in the stack operated properly by hand. The CO₂ dropped from 13 per cent to 7 per cent, making an average CO₂ content for this curve

10.5 per cent, which represents 5 per cent preventable waste of fuel.

Curve No. 3 indicates a series of CO₂ readings for a like period of a boiler without a damper of any kind, from which it may be noted that the first gas sample analyzed 8 per cent CO₂. This diminished to 5 per cent for the fourth sample at seven minutes, making an average of 6.6 per cent CO₂, or 14½ per cent preventable waste of fuel.

EFFECT OF PROPERLY OPERATED STACK DAMPERS ON CO₂ CONTENT OF FLUE GAS

	CO ₂ content: per cent				Av'ge.	Pre-ventable waste, a month.	Fuel wasted from this source in a plant using 1,200 tons coal a month.
	Gas sample No. 1	Gas sample No. 2	Gas sample No. 3	Gas sample No. 4			
Automatic damper	15	15	14	13.2	14.2	1	12 tons
Hand operated damper	2	13	12	10	7	10.5	5 60 tons
Without damper	3	8	7.5	6	5	6.6	14.5 174 tons

A big organization such as a railroad owns many stationary boiler plants. Because of separate supervision and for other reasons, such plants are seldom in like condition, and on account of the distance from one to another comparisons are difficult to make. There is, however, a friendly rivalry between employees of the various plants, and the writer has often been asked by the stationary engineer how the physical condition of his plant compared with other plants on the road. In order to satisfy this demand a report was made up showing the rank of the various plants being supervised, as determined by inspection. To arrive at a fair rank, a percentage allowance based on relative importance was made for each item, such as condition of boiler setting, presence of dampers, scale, soot, steam and air leaks, pipe insulation, interest of local forces in the plant, effort to follow instructions, etc. The total of all allowances was 100 per cent and rank was reached after deduction on all items not up to their allowance. The report bore the name of the location of each plant, with its rank. This report was sent to all concerned from general officers of the road down to the plant engineer. The report served its purpose. The fellows who found their plants down around 30 per cent and 40 per cent felt the sting of comparison with plants ranking 92 per cent, and they promptly began to make the improvements which it had otherwise been impossible to secure. One plant of 400 hp., on which considerable time had been expended in trying to arouse interest in its improvement without result, rose from the rank of 30 per cent to 82 per cent in 30 days after the first of these reports was issued. The results were so gratifying that it was issued at regular intervals until the plants were in the best physical condition possible under existing circumstances.

As a rule the boilers are the most uneconomical units in the power house. There are instances where plants are equipped with expensive turbo-generator sets, compressors and other engine-room equipment which are maintained year after year in first-class condition, while the boiler equipment in the next room is permitted to deteriorate. That this difference continues to exist is an absurdity, but it does exist in many cases. On railroads expensive facilities in the form of engine houses and repair shops are erected, manned and maintained, very properly, for the purpose of keeping locomotives in good, efficient, economical condition. In contrast with this practice the proper maintenance of stationary plants is neglected or ignored until after a few years' service, when it suddenly fails to perform its natural function. This contrast should be corrected, to the advantage of the boiler plant. It is cheaper to repair a plant when repairs are needed than to allow defects to accumulate.

Other features of maintenance and operation are fully worthy of consideration. Surfaces which waste heat by radiation should be insulated. The use of exhaust steam to heat feed water is so commonly practiced that it need only be

mentioned. It is important, however, to keep feed water pumps moving continuously but as slowly as necessary, thereby maintaining the highest temperature possible with the steam available. Baffle walls should be kept tight to prevent the short-circuiting of the gases. Air, steam and water valves and connections should be kept free from leaks and the plant engineer should make regular inspection for these defects.

Scale and soot on boiler tubes offer great resistance to the transmission of heat to the water. Flues should be rattled or bored frequently enough to keep scale knocked off. Soot should be removed by dry steam or air at least once on each shift. A good mechanical soot blower is one of the most economical and satisfactory devices around a boiler plant. Every boiler should have one.

There are other features about a boiler plant which affect economical operation—too many to be covered by one paper. If all concerned in the operation of a plant are made to realize the good results it is possible to obtain and enthusiasm is created in working out the possibilities one by one, the defects will be overcome, with the result that the employees will be better satisfied with their work and economy will come into its own.

CANADIAN PACIFIC TO EXTEND ANGUS SHOPS

In order to speed up on the construction of equipment required on the Canadian Pacific large extensions are being made at the Angus shops in Montreal. These extensions will cover a quarter of a million square feet and are expected to cost approximately a million dollars. The largest addition will be made to the passenger car shops, amounting to 71,000 sq. ft., while over 58,000 sq. ft. will be added to the locomotive shops and 42,400 to the freight car shops. The following are the detailed particulars of the extensions:

Locomotive Shop.—The extensions to the locomotive shop will consist of an addition at each end of the present shop to give an additional floor area of 58,000 sq. ft. The construction will be steel frame with concrete foundation and brick walls. Mastic floor will be placed on the west end extension and wood block floor on concrete in the east end extension. The east shop extension is to be used as a running shed, and for this reason pits with mill type smoke jacks will be installed. All of the skylights will be constructed of wood and mill type ventilators will be used throughout this shop.

Freight Car Shop.—The addition consists of an extension to the present building at the west end, 106 ft. wide by 400 ft. long, giving an additional floor area of 42,400 sq. ft. The construction will be steel frame with concrete foundation, brick wall, wood floor and roof similar to the present building.

Pattern Storage.—This shop will be extended at the west end 75 ft., and will be 50 ft. in width, and a three-floor fire-proof building. The construction will be steel frame with concrete foundation, brick walls, steel sash, concrete roof and floors.

Passenger Car Shops.—The new work consists of an extension 102 ft. by 161 ft. between Shops 2 and 4, and 137 ft. by 161 ft. between Shops 1 and 3; and a 137 by 239 ft. east end extension of Shop 3, giving a total increased area of 71,000 sq. ft. The construction will be concrete foundation with brick walls, mill type roof, concrete and mastic floors.

These shops will be all served from the present transfer table, the pit of which is being extended.

Car Electrical Shop.—This is a new building 62 ft. wide by 362 ft. long, giving a floor area of 23,000 sq. ft. The construction will be steel frame with concrete foundations, brick walls and acid proof mastic floor.

There will also be built a new planing mill shelter, an addition to the dry kilns, a high capacity track scale and a 50-ton coaling plant.

Tools Ground Direct from Bar Stock

PRODUCTION OF LATHE AND PLANER TOOLS

**Grinding from Bar Stock an Economical Method of
Manufacture; Centralized Tool Service Advantageous**

BY E. G. BLAKE

Sales Engineer, Alfred Herbert Ltd., New York City

A REVIEW of the progress made by grinding as an economical method of removing metal shows a somewhat surprising number of engineering firms still making lathe, planer, shaper tools, etc., by the old fashioned method of hand forging. It is with the thought in mind of pointing out that grinding may be substituted for this method that the following is written.

Comparative Costs

The writer has no data available on the cost of forging tools, but the practice is so well known that it will only be necessary to give an idea as to the cost of grinding to leave no doubt as to the comparative cost of the two methods. Means are available today whereby a tool of any desired shape may be ground from stock of 1-in. by $\frac{3}{4}$ -in. section in two or three minutes according to the shape, and other sizes in a proportionate time. It probably would take a blacksmith more than two minutes to heat the steel before he and his helper commenced a similar job. Hand forging is at best a rough and inaccurate method of producing any desired shape and carries with it the danger of maltreatment due to the hammering of the steel above and below certain heat limits. It is a well known fact that a large amount of high speed steel is ruined through bad heat treatment in the forging operation, and any method which tends to eliminate this waste should be considered. The grinding of tools from bar stock should, of course, be performed dry and the tool hardened afterwards. It will readily be understood that a tool ground on a machine especially adapted for this purpose to a predetermined shape requires very little re-grinding after the hardening operation, whereas a forged tool needs to be corrected on a tool grinder or by hand to gages, and the cost of this is more in itself than that of the rough grinding operation on a machine specially adapted for the purpose. Add to these two costs that of hardening and we have a cost about one-sixth of that of forging and subsequent grinding.

Effect of Grinding on the Steel

Bearing on the question of forged tools a paper was presented as recently as December 19, 1919, by G. W. Burley of the University of Sheffield in London before the Institution of Mechanical Engineers. Mr. Burley headed his paper "Cutting Power of Lathe Turning Tools," and stated that the shape of the nose of the tool which was adopted as the standard in the original investigations is such that it can be obtained from a plain bar by the single process of grinding, but that in the case of the majority of shapes it is necessary to have the nose shaped initially by forging and finished by grinding. It appeared desirable, therefore, to determine whether this initial forging operation had any influence, deleterious or otherwise, on the quality of lathe turning tools. After giving details of the test bars forming the subject of this test, Mr. Burley stated that the results of the trials demonstrated that there was no appreciable difference between the cutting power of a forged turning tool and that of a similar unforaged one provided that both tools are made of the same kind of steel and passed through the same hardening process. An excerpt from the paper follows:

"This conclusion has been confirmed by results obtained incidentally from an extensive investigation which was made on tool steels as a special war research in the University of Sheffield. In this investigation nearly 1,000 individual tests were made on 332 tools of similar shapes under identical conditions, one-half of this number having forged noses and the other half unforaged ones. An analysis of the results of the investigations shows that the two kinds were fairly evenly divided, practically one-half of the tools of each kind giving results above the mean, and the other half below with an average superiority of not quite 0.25 per cent in favor of the forged tools."

It would appear that the difference between forged tools and tools ground from bar stock, is negligible, and this information coming as it does from an authentic source should be particularly appreciated in view of the shortage of skilled

toolsmiths existing at the present time. This apart from the fact that experiments have shown that tools can be produced from bar stock by grinding much more economically than by the old time method of hand forging and grinding.

How Grinding from Bar Stock Affects Tool Design

Previous discussions on the subject of tool design have taken for granted that grinding is a long and laborious operation, and therefore the greater part of the remarks have been devoted to tool forging to be done in such a manner that subsequent grinding should take as short a time as possible. Due to the progress made by grinding, some thought should be put into the question of tool design, with a view to taking advantage of the many economies which can be effected by the grinding of tools from bar stock. Bent and offset forged tools are very often used without any thought as to why they should be bent or forged, although it is generally known that a bent tool is not so efficient as a straight tool, as the pressure on the bent tool is inclined to tilt the tool sideways owing to the width of the tool shank acting as the clamping base, whereas the straight tool takes the weight of the cut somewhere near the center of the section, which gives a support from the full length of the tool shank.

Tool Ground from Straight Bar Stock Applied to a Lathe.

The illustration shows the application of a tool which has been designed to substitute for the offset tool which is costly to forge, weak when made, and is soon rendered useless by regrinding, while the straight tool is stronger and has considerably longer life, as it will stand much more regrinding. This is a typical instance of what can be done with a little thought, bearing in mind the economies attached to the principle of grinding from bar stock. Almost any job can be handled in the same manner.

Toolholders—Butt Welding

Substantiating the statements as to the costly method of tool forging is the growing tendency to use tool-holders and tools with welded or brazed tips. It would appear at first that the use of tool bits and toolholders is economical, but our observations have shown us that this is not the case. Certainly the question of initial expense is in favor of the toolholder proposition, but when it is considered that only approximately 60 to 70 per cent of the steel purchased in the form of tool bits is actually used, it puts a different aspect on the case. All points considered, this latter feature seems to us very convincing, for, while the initial expense in purchasing tool bits is small, when the total purchase of high speed steel is taken into consideration and deducting from 30 to 40 per cent as absolute waste, it would appear

that any other method which would reduce this waste should be considered.

The same argument applies to tools with brazed or welded bits. The life of these is very much limited because of the tip wearing in thickness due to regrinding. It is not logical to expect a tipped tool to last until the regrinding reaches the bar stock; therefore it is safe to assume that the same waste occurs as in the case of toolholders. In addition it is quite an expensive process to make the tipped tools in the first place. Using solid stock as an alternative offers very little better results owing to the fact that considerable waste is experienced when the bar stock becomes too short for use. A solid tool has, of course, the great advantage of being the best type for absorbing the heat generated by the cut, and consequently stands up longer. Our observations show that butt welding high speed steel to a carbon steel shank is the only way in which the full advantages of the solid tool can be obtained without the waste entailed by the use of toolholders and tipped tools. By welding a piece of high speed steel, one-third of the desired length, to a piece of low carbon steel of the same section, a tool is obtained which has the very desirable features of the solid tool and can be used by regrinding or re forging right back to the weld. Further, by using the high speed steel piece one-third of the desired length, the high speed steel portion of the tool itself has the necessary support afforded by the tool rest without the strain affecting the joint. This method is worthy of the consideration of anyone interested in the economical production of high speed steel tools.

Centralized Tool Service

Centralized tool service has often been considered, but very little progress has been made in this direction. No one seems to doubt the advantages that such a service offers, but one of the reasons why this method of making cutting tools in a shop is not adopted is because of the undesirability of having a blacksmith's forge connected with the tool-room. If the forging method was superseded by grinding, the necessary machines could be installed in the tool-room and would not interfere in any way with the organization in that department. In many engineering works the design of cutting tools is in the hands of the machine operators themselves, which results in a larger number of standards than is necessary and a consequent larger number of tools lying idle. Great economies can be effected by altering this state of affairs. In the first place the number of standards could be reduced to a minimum and a constant supply of tools always be available in exchange for dull or broken ones. This would also mean that the operators would spend less time at the grinding machine while their own machines were lying idle. Tools being ground to certain standards, assuming that these standards have been found to be the most efficient for the purpose, would consume less power in operation and would stand up to the work longer.

HERBERT SPENCER.—It may prove interesting, if not something of an inspiration to railroad men to know that Herbert Spencer, the greatest philosopher of modern times, began his career as a civil engineer on the London & Birmingham Railway. He was employed on this railroad and the London & Gloucester Railroad from 1837 to 1846, and according to his biographers was a very good engineer. In 1848 he became a sub-editor on *The Economist* and in 1850 published *Social Statics*, his first notable book on philosophy. The one hundredth anniversary of Herbert Spencer's birth was celebrated April 27. He was born at Derby, England, of Methodist and Quaker parentage. His father, who was a schoolmaster, did not have the means to send him to college, but his uncle offered to send him through Cambridge. He declined this offer, however, and chose to begin his career in railroad service.

HOW THE MASTER MECHANIC INCREASED PRODUCTION*

Better Mutual Understanding and an Appeal to the Sporting Instinct of the Men Brought Results

BY E. F. JONES

JACK BRADLEY, Master Mechanic of the Big Shops, sat deep in thought. From all sources came the insistent cry for increased production, but there was no response. Everywhere he saw signs of restlessness. He, too, felt the daily surge of new and powerful emotions. The terrible strain of war with its great griefs, had, with the signing of the armistice, left the human family in a high fever of nervous reaction. He knew that it must run its natural course, but that ways must be found to keep it within due bounds. Humanity was on the march. Old ideas and customs had been torn loose and cast aside. Men who faced death in the trenches had come home with a new conception of life and were not content to pick up the threads of civil life where they had left them at the call of duty.

Walking through the shops that morning, Jack had looked at the men more keenly than usual. What were the thoughts and the feelings of these men who made up the working

He knew that the same chord struck with a rough hand would have produced a rasping discord. Why did the human family realize that years of study and training were required to bring out the tones of harmony in musical instruments, and neglect entirely the training that would bring harmonious response from the most wonderful instrument of all—the human body and soul?

Thinking deeply of this little incident Jack glanced at his desk covered with letters and reports. He knew without looking through the mass that not one letter or report dealt with the human factor of the big shops in a broad constructive way. Thinking back through the years past he realized that all the improvements for the men's comfort and health had been carried out according to a state or federal law, and none through the company's desire to make the workmen healthier, happier and better men. He realized deeply how production had suffered by this short-sighted policy, and determined, so far as was in his power, that not another day would pass under such a policy.

Calling in his chief clerk, Jack asked for a meeting of all foremen at one o'clock. As the word passed around it caused some wonderment, as a meeting had been held several days previously, and it was a very unusual thing to hold another so shortly. Promptly at one the foremen trooped into the big office of the master mechanic. They did not perceive the keen look bestowed upon them by "the old man," but it was the same look he had used in his walk through the shop that morning.

Jack felt a new sense of appreciation and confidence as he closely studied the faces of these foremen who had gone through many hard days and trials with him. As his eyes rested on the general foreman he felt a chill of apprehension. Here was a man of the old school who had won his position by his ability to drive and lash men in their work. He was of the bulldog type in build, manners and speech. In the presence of the master mechanic he was servile; in the presence of the men, domineering.

After seeing that everyone was comfortably seated, Jack started slowly and carefully to explain the object of the meeting. He told of his own feelings through the war period and the unrest he had felt in the days following. He told of the surging unrest of the whole world, and the need of meeting this condition face to face and in man fashion.

"We have got to play the game under new rules," said Jack, "and here they are. Our policy as supervisors has been to drive and dictate. We have reaped a crop of distrust and resentment. We are all together at this shop, yet it reminds me of a house with two rooms and both in darkness. The men in one room and we in the other are each planning new ways to get the better of each other. Neither can see what is going on as the darkness of secrecy and distrust is too intense. It is our duty to clear our room of this darkness and invite the men into a clear atmosphere of understanding and trust. This move will breed suspicion at first and we must prepare for rebuffs and disappointments. The clear light of our room however will soon work its cheerful power over the men, and they will gradually step in and look around furtively for the nigger in the wood pile. Frank discussions and above-board dealings will be the order of business in that newly lighted room, and soon those men will realize that we are doing our best to play square and

After Seeing That Everyone Was Comfortably Seated, Jack Started Slowly and Carefully to Explain the Object of the Meeting.

force of the big shops? Their state of mind showed in the apathetic manner in which they performed the various jobs. The atmosphere was comparable to a damp day. Coming back to the office he took particular notice of a swarthy Italian laborer doing a heavy lifting job. Although strong and robust the man worked in a listless manner. Walking up to him Jack said "Good morning, Tony," and asked a few questions about sunny Italy. Instantly Tony straightened up and saluted. With intense and passionate feeling he told of the land of his birth, of the suffering brought to his people by the war. His dark eyes shone eagerly and brightly as he told of his active war service and his voice grew a little husky as he visioned again the loss of his boyhood friends.

Several minutes later Jack looked out of his window and saw Tony working with new spirit and energy. He had gently and delicately touched the human chord in Tony's nature, and released a pent up flood of feeling. A little tangible personal interest had made Tony a happier man.

*Entered in the Railway Mechanical Engineer's prize story contest.

will go back to their dark room and tell their story of the new rules. The atmosphere of their room will gradually change to light and cheer. We then have a well-lighted cheerful house with free and friendly interchange of thought. This is the theory and our duty is to work it out in a practical business manner.

"Our first step is to interest the men in the work of these shops as a whole. They know nothing of our month's program, and never hear of their good work. We take the credit for that. When things go wrong, they hear of it through a 'bawling out,' which is frequently accompanied by curses. Every curse robs the treasury of this company by adding bitterness to the man's soul. A man in this mental state has a vicious desire to strike back and usually does. This striking back takes the form of destroying material, loafing, and other ways which only a bitter-minded employee can think of. The commonest expression of these employees is 'To Hell with it!' Curses and lack of humane interest on our part were the seeds which brought forth this terrible crop of destructive spirit.

"We have got to realize, men, that we reap what we sow and the man who sows must be responsible for his crops. Our new seeds are to be manly language and humane interest, and the crops will be good will and concentrated effort to please. We have hammered the men for years to increase production and the net results of constant hammering are a decreased production. This proves our failure and only stubbornness and willful blindness will keep us on the rutty road of failure, when there is a broad, smooth highway nearby, leading to success.

"Results count, not misdirected efforts. Over there hangs the engine program board. I see it every day and so do most of you, but the men seldom see it, and know little of its use. Tomorrow the board goes into the shop and its purpose will be explained to every man. We will show how it keeps us informed of our monthly allotment of work and keeps us posted on our progress. We will keep this progress record in a way that all can read and understand quickly and easily. A graph board of 31 days will be placed next to the engine board. A bold straight line running from the lower left corner representing the first day of the month, to the upper right hand corner, representing the last day, will be the guide to show our anticipated daily progress. What is actually accomplished will show by a different colored line. This line will constantly remind the men if the shop is falling below the line of real effort, or is going above the line and keeping above.

"The natural instinct of man will make him fight to get above the line and a natural pride will be felt as he sees his efforts pictured in a way that means some real accomplishment. We have 172 engines assigned to this shop and to most of us they represent merely big pulling machines. They are a great deal more than that. They represent the mental and physical labor of hundreds of men and the finished locomotive remains the living part of what those men gave. It accomplishes its daily task successfully or otherwise, according to the quality of labor that made it a productive factor. Every day a large bulletin board will contain the performance record of each engine. Each man will be eager to see his workmanship stand the test. If a failure occurs the exact cause will be briefly explained and if due to faulty workmanship, the failed part, or a rough sketch of it, will be put on view for one day, under the number of the engine.

"No criticism will be needed, as the defective part will tell its own story of neglect or carelessness more effectively than words. This mute object lesson is not given to shame the employee for his neglect; its object is to educate and to teach its lesson in a way that reaches deep into the man, and awakens his sense of responsibility, showing him what a vital part he is of the entire organization. A new and

powerful interest will be awakened in that man and its lesson will react on the other men as they will picture importance of their work and realize that they must not be the weak link in the chain.

"After these new policies have awakened the interest of the men, we will ask them to re-name their grievance committee, as that name suggests improper relations and discord. I will suggest the committee be named conference committee and its object will be to promote harmony, good will and confidence and to talk over all shop conditions in a big constructive way. We must educate our men to the point of view where they will begin to suggest economical ways of operating. If they say a certain part of the work can be expedited by making certain changes, and we cannot

"Red, What Do You Think of Our New Policies?"

agree, we will give them an opportunity to prove their point. This action on our part will make them very eager to show they are right and it will place a burden of responsibility on them which will broaden their vision and have a good effect on their future suggestions. Giving a workman the viewpoint of personal responsibility and creative opportunity to work out his own ideas on a job will improve his mental health and strengthen his loyalty. He keenly relishes the idea that he is a recognized factor in our shops and will respond vigorously. A man with this spirit will swing his hammer with twice the force, and oftener. Mental health is just as important as physical health in all our efforts. When you get this fact honestly worked out, the problem of increased production is solved, and it is the only solution."

Jack paused, and then slowly said, "Men, are you with me?" He had read his answer during the pause. Their faces already reflected the new spirit and their spontaneous assurances gave Jack high hope.

The general foreman sat red-faced and bewildered looking, and as the men left his office, Jack asked him to remain and said, "Jim, you don't agree with me on this, do you?" and Jim blurted out, "Hell Jack, I'm no Sunday school teacher." Jack replied, "No, Jim, this is a man's job. Times have changed. It's the way of the world. Nothing stands still. We must go forward in step with the new conditions or drop out of line. It's going to be hard on you, Jim, but I want you to give the new rules your best efforts."

The general foreman left the office without comment. As the days and weeks went by, Jack felt the gradual improvement in the shop's pulse, and knew that the new medicine was taking hold. This improvement was slow and there were relapses. Jim, the general foreman, could not play the new game, and sent in his resignation.

One day a department foreman came to Jack and stated that he would have to fire one of his best men who was agitating continually and telling the men that a crooked game was being played by the management. This man was a natural rebel and leader, and Jack knew he had great influence over the other men, so he determined to convince him that the game was straight. Calling him in later in the day, he said, "Red, what do you think of our new policies?" Red was a little confused but shot back, that the management was "pulling the wool" again.

Starting in earnestly and slowly, Jack detailed the changes that had come over the world, and how imperative it was for everyone to play square. He surprised Red by admitting that the higher officers had made many mistakes in dealing with the men, and said most of these mistakes were due to their lack of contact with the men. Men who were out of actual contact did not understand each other's problems. "We are going to get closer together in this new game and we want you to play fair just the same as you would in a game of baseball. The only difference between baseball and business is that business is played by everyone and the most interesting game in the world if played on the level. What would you do to the fellow in a baseball game who continually tried to cut his corners or spike the basemen, and hollered murder when he was caught?" Red instantly answered, "I'd break his damn neck." "Well," continued Jack, "that's what is going to happen to all the crooked players in this game of business. Clean business will not tolerate crooked players, and they will be put out of the big game, and some of them crippled so they can never play again."

Red's interest was awakened and his manner changed.

A Shrill Boyish Voice Called "Hey Jack, How's Your Golf?"

The earnest, sincere way in which Jack pictured the game, appealed to Red and he eagerly began to suggest ways and means of improving the shop work. For a full hour they went over various phases of the work, and Jack learned more in that hour than he had in a month's inspection. The ingenious Red became one of the strongest players, and supported the new ideas with all the strength of his virile personality. The shop pulse now began to show decided improvement. The men walked with a snappier step, they swung their hammers with new spirit, and the general atmosphere of the shops was surcharged with vigorous vitality and cheerfulness. Engines began to leave the shops ahead

of their schedule time, and the graph chart showed the month's work finished three days ahead of time. The conference committee recommended an increased allotment for the next month, and the end of that month showed the graph with a perfect record. Not once did the men allow their progress line to go under that forbidding line. Their fighting pride would not allow it.

The next feature to be introduced to the shop, was a shop news board, where the most interesting items of the daily shop mail were posted each morning. Hitherto the men had to depend on the "stove pipe" committee for their shop news. Now they were given this news in a brief authentic way and the eagerness with which they read these items was ample proof that they had been starving for mental shop food. The daily serving of this mental food satisfied this hunger and developed an interest in the work of the entire shop that was marvelous.

The increased production of the big shop was of course noticed by the general superintendent of motive power and he wrote Jack a letter of congratulation. Jack was too big a man to accept the entire credit and wrote to the general superintendent asking that he include the entire forces of the shop in his congratulations. This spirit pleased the general superintendent, and his next letter was stronger than the first, and included the entire personnel. Jack personally placed that letter on the shop news board, and felt that it represented the beginning of a better understanding between the management and the men.

Several days later the general superintendent visited the big shops and noticed the general air of good feeling which abounded. As they walked through one of the engine houses, a shrill boyish voice called "Hey Jack, how's your golf?" Turning quickly, Jack noticed a grinning grimy face peering over the top of one of the pits. The voice had a familiar sound, but the grime was so thick that he failed to recognize the face, so he walked over to the pit and peered down into the smiling eyes of a youngster who had been his caddy at the golf club. Jack's hobby was golf, and a warm friendship had developed between him and the boy. The cordial friendly greeting of the boy warmed Jack's heart and brought a big smile to the serious face of the general superintendent. Asking the boy a few friendly questions, they passed on.

Returning to the office of the general superintendent asked Jack to tell him the entire story of the new spirit in the shops and Jack gladly complied. The general superintendent was deeply interested and asked Jack's aid in developing the new spirit at all the shops. This Jack readily agreed to.

Months of patient work brought the same good results at the other shops, for the men were of the same mould and needed the same humane treatment and mental medicine to restore their interest and vigor. The new spirit spread throughout the railroad and Jack felt great satisfaction when the general manager recognized it as the main factor in the greatly increased efficiency.

The men had found that true happiness could be found in their work if they played square and they could trust the management to play square with them.

PRESENT COST OF ROLLING STOCK IN FRANCE.—A French paper called the "Journée Industrielle" has recently made a study of the present cost prices of rolling stock in France. The results of this investigation show that it costs from \$4,050 to \$5,400 for a box car, \$3,375 to \$4,725 for a gondola car, and \$2,025 to \$2,700 for a flat car. The cost price of a modern passenger car, equipped with the latest improvements, is about \$67,500 for a first-class, \$43,875 for a second-class and \$33,750 for a third-class carriage. The prices noted are given at present rates of exchange.

A MODERN TOOL ROOM HEAT TREATING PLANT

Electric Furnaces and Pyrometers Installed at Ft. Wayne Shops of the Pennsylvania System

ACCURATE temperature control in heat treatment is one of the most important considerations in insuring good tool service. This is a fact which is coming to be generally recognized in railroad shops, and the use of special equipment has for several years been replacing the old hand forge method of hardening and drawing these tools.

A new heat treating plant has recently been installed in the tool room at the Ft. Wayne, Ind., shop of the Pennsylvania System in which complete provision has been made to insure uniformity of results with the expenditure of a minimum amount of labor. The plant is adequately equipped for handling all classes of tool work and is of particular interest from the fact that electric furnaces and pyrometers are used for the hardening operations.

The plant is called on to handle a wide variety of work,

Electric Furnaces and Switchboard at the Ft. Wayne Heat Treating Plant

some of it in considerable quantities. The largest output is beading tools and flue expanders. About 300 beading tools are treated a week, for use at Ft. Wayne and a number of other points on the system. The output of flue expanders is considerably less, but in putting them through the plant they are handled in lots of about 200 at a time. The remainder of the output is made up of special tools of various kinds, such as taps, reamers, special milling cutters, inserted cutter blades, shear blades and punch and die work. Several examples of the variety of special tools turned out are shown in one of the photographs. In the manufacture of many of these tools, axle steel, case hardened, has been used.

The Electric Furnaces and Equipment

All hardening and annealing operations are carried out in two electric furnaces. These furnaces are of different types and provide different temperature ranges. The two are used together on hardening operations. The low temperature furnace, shown at the right in the illustration, has a maximum temperature limit of about 2,000 deg. F. and is used for annealing and hardening carbon steel tools, heating case-hardened carbon steel tools for quenching and pre-heating tool steel to a temperature of about 1,800 deg. F. The high temperature furnace has a maximum temperature limit of 2,500

deg. F. In this furnace the pre-heated tool steel pieces are finished to the proper hardening temperature, ranging from 2,250 deg. to 2,300 deg. F.

Both furnaces are of the muffle type but differ materially in the type of heating elements used. The elements in the smaller furnace are of the so-called hairpin type. Surrounding the refractory muffle are four slabs of refractory material provided with longitudinal slots in which fit the hairpin heating elements. These elements are inserted by removing the furnace front, which exposes their closed ends, and are placed entirely around the top, sides and bottom of the muffle lining. At the rear of the furnace, the ends of adjacent elements are joined by a series of connector blocks, with the exception of one pair to which the lead terminals are attached. This furnace operates on a maximum of 55 volts which is obtained by means of a regulating transformer. The secondary winding is divided into sections, each of which corresponds to a different voltage and the terminals of these sections are connected to a bank of single knife switches by means of which any section, or combination of sections, may be connected to the heating elements of the furnace. There are five of these sections, which afford a wide range of voltage and temperature regulation.

This furnace has a heating chamber 26 in. long by 8 in. high by 12 in. wide and has a full load rating of about 15 kilowatts. At full load about one hour and thirty minutes is required to bring the furnace up to its maximum temperature limit of 2,000 deg., after which this temperature may be maintained on about two-thirds of the full load rating.

The high temperature furnace has a heating chamber 18 in. long, 8 in. high and 12 in. wide. In this furnace the heating elements are carbon plate resistance piles which are placed inside the muffle on both sides. These plates are about $\frac{1}{4}$ -in. thick and rest on heavy graphite blocks at the bottom. At the top the two piles are connected by a set of heavy transverse carbon plates. Graphite electrodes extend vertically through the bottom of the furnace and bear against the bottom of the graphite blocks, one on either side of the furnace. Hand wheels located conveniently in front of the furnace, through beveled gears, operate elevating screws which in turn bear against the lower terminals of the electrodes. The current thus passes from one electrode up through the carbon resistance pile on one side of the furnace, across the top to the carbon slabs, down through the carbon resistance pile on the other side of the furnace and out through the other electrode. Temperature control is obtained by varying the upward pressure against the carbon piles and hence varying the resistance.

Like the lower temperature furnace, current is obtained from the secondary of an air-cooler transformer which is wound in one section. The maximum voltage for this furnace is kept down to about 30.

This furnace has a full load rating of 30 kilowatts, at which about one hour and thirty minutes is required to bring it up to its maximum working temperature. Considerably less power is required to maintain a uniform working temperature after the furnace has become thoroughly heated.

The switchboard, shown at the left in the illustration of the furnaces, contains a switch, circuit breaker and an ammeter in the primary circuit of the high temperature furnace transformer. The pyrometer is connected to a double-throw switch by means of which it may be connected to the thermo-

couple in either of the two furnaces. The switchboard for the low temperature furnace is attached to the side of the furnace frame.

Other Equipment

For low temperature drawing work an oil burning furnace of the oil bath type has been installed. Above this furnace has been placed a short monorail from which is suspended a chain hoist for handling the basket container into and out of the oil bath. As will be seen in the illustration, the temperature of the oil bath is indicated on a thermometer which forms part of the equipment.

A small oil burning muffle furnace has been installed to take care of various odd jobs for which the other equipment is not adapted. This furnace is useful for small forging jobs which it is desired to perform in the tool room and it is also used for short heats in hardening lathe centers and other pieces which it is not desired to heat all over.

The equipment of the plant also includes three quenching tanks containing water, salt water and oil, respectively. The

The Oil Bath Tempering Furnace and Small Oil Burning Muffle Furnace

oil and salt water tanks are jacketed and cooled with flowing water. These tanks are conveniently located to the electric furnaces. In hardening carbon steel tools they are first quenched in water till the vibration ceases and are then transferred to the oil. High speed steel tools are quenched in oil.

Classes of Work Handled

When a run of high speed steel tools is to be treated both electric furnaces are used. This reduces the time required for the complete heating operation to that required to pre-heat the tools to about 1,800 deg. in the low temperature furnace. Work of this kind is handled in lots in order that as long a run as possible may be obtained without the necessity of cooling down and reheating the furnaces.

When annealing is to be done, the parts to be annealed are placed in the furnace at the end of the day's work, brought to the required temperature and allowed to cool down in the furnace during the night. This work is thus a by-product of the regular operation of the plant and costs practically nothing for power or labor.

Reference has already been made to the variety of special tools which are handled in the heat treating plant and to the fact that some of these tools are made from axle steel and case-hardened. The use of this material offers a number of advantages where occasional jobs come into the shop requir-

A Number of Special Tools Representative of Work Turned Out of the Heat Treating Plant

ing special tool equipment and also for tools which are regularly but infrequently used. This material is not used for cutting tools which are expected to operate at high speed.

In the illustration showing a number of these special tools, the first one at the right is a hob which was made for use in replacing a broken worm gear from a coaling station on the line. This cutter was machined out of axle steel, sent to the blacksmith shop for case-hardening and reheated in the tool room for quenching. By its use the new gear was cut and the plant returned to service with only a few day's delay at an expense from which the cost of tool material was practically eliminated. Such tools manufactured from tool steel are difficult to harden without serious risk of fracture and loss both of the material and time expended in their manufacture. The case-hardening process is comparatively easy to handle and where the quenching heat is under control, as it is in the heat treating plant, perfect results are assured. Other tools of the same material shown in the photograph are a large 45 deg. reamer, a special reamer for finishing the piston rod pits of crossheads and a large special tap.

Among the other tools which have been developed and manufactured in the tool room are shown two sets of punches and dies for cutting piston rod and valve stem swab rings and a special three-fluted cutter for machining the crosshead key slots in piston rods. This work is done by first drilling a hole of the proper size at one end of the slot, setting the rod up on a milling machine table with the cutter inserted through the hole and finishing the slot with the cutter.

At the left in the illustration is shown a set of punches and dies for perforating driving box grease cellar plates. The punches are mounted in short sections of hardened steel which in turn are secured to a soft steel bar. The die blocks are also formed in short sections and similarly mounted on a bar of soft steel. The punch on which the work is done operates at the rate of 80 strokes per minute. Each stroke

perforates two rows of holes and the work is complete in 19 strokes at a total time of about a quarter of a minute per plate. The finished plate is clean and smooth with no distortion or fins at the edges of the holes whatever.

The equipment of the plant includes a Scleroscope, which instrument has proved of value in checking up the work of the plant and determining the temperatures to be used on various steels.

Results

The plant has justified expectations as to providing better and more uniform service from the tools turned out. Before this plant was installed, in making up a lot of flue expanders it was the regular practice to include a number of extra sections in each lot. These were always needed to replace sections broken in hardening. Since the electric furnaces have been in use, no breakages of this kind occur and the physical qualities of all of the hardened sections are exactly alike. When beading tools were hardened in the blacksmith shop they frequently broke in the shank, it being impossible to harden them all over alike. Now these tools are heated to a uniform quenching temperature all over and so far no trouble has been reported from failures in service. The same conditions apply with respect to special rivet sets and air hammer chisels. These tools are annealed, hardened and drawn at a uniform temperature all over.

Not the least of the benefits which have resulted from the operation of this plant is the saving in labor as compared with the old methods of heat treating tools in the blacksmith shop. To take care of this work it formerly required two men on blacksmith fires. Now, one man is easily able to take care of the work, which from the tool hardeners' standpoint is performed under conditions far less exacting. The operation and maintenance of the electric furnaces requires no knowledge of electricity, and skill in regulating furnace temperatures within narrow limits is readily acquired with a small amount of practice.

THE DRIFTING VALVE

BY S. H. LEWIS

When a locomotive drifts the fire box gases, at high temperature, smoke and the atmosphere are forced into the cylinders and destroy the oil which is supplied for lubricating them. These elements leave abrasive deposits and cause the cylinder packing to break or wear out in a small percentage of the time that it would otherwise be useful. This in turn decreases the power of the locomotive and in point of economy and service the exclusion of the gases, smoke and atmosphere is desirable and important.

To prevent the creation of vacuum within the cylinders, numerous valves have been invented for supplying steam to the cylinders while the locomotive is drifting, and the best known of these may be considered as being of three types, viz., hand-operated, semi-automatic and automatic.

Owing to human fallibility the hand-operated valves are unreliable and dangerous. As they are not opened regularly they do not prevent the creation of vacuum at all times when the locomotive is moving and damage results. As they are not closed with regularity they have caused locomotives to move or slip when unattended, and have increased the liability of personal injury and damage to property.

The semi-automatic valve employs a pressure operated valve in conjunction with a hand operated control valve which is supposed to be opened at the beginning of a trip and closed at the end of the trip. This type is open to the same criticism as the hand operated type with respect to human fallibility.

The automatic valve is either pressure operated or mechanically operated and will give the desired results only where

such valves prevent the pressure within the cylinders from falling below atmospheric pressure *at all times* when the locomotive is moving.

From the foregoing it may be reasonably concluded that a drifting valve should be automatic, and as expense is increased and service impaired by the creation of vacuum in locomotive cylinders, it is obvious that a drifting valve should not depend for its operation upon vacuum created in the cylinders. It is equally true that a drifting valve should not depend for its operation upon compression created in the cylinders as compression and vacuum occur simultaneously in opposite ends of the cylinders.

Classification of Drifting Valves

The steam supply pipe should be arranged to prevent condensation and the delivery pipe from the drifting valve may be so arranged that *superheated* steam may be supplied to the cylinders through the valve chests and steam distribution valves or *saturated* steam may be supplied through the same channel, or *saturated* steam may be supplied direct to opposite ends of the cylinders. These methods are subsequently referred to respectively as arrangement *A*, arrangement *B*, and arrangement *C*.

In arrangement *A*, the steam is delivered to the *saturated* steam compartment of the superheater header or the dry pipe, and passes through the superheater units before reaching the steam chests and cylinders; in arrangement *B*, the steam is delivered to the *superheated* steam compartment of the header or piped direct to the steam pipes or steam chests, and in arrangement *C*, the steam is delivered to the cylinder clearance spaces through non-return check valves. The check valves serve to prevent the passage of steam from one end of the cylinder to the other when the throttle is open.

With arrangement *A*, the drifting valve may remain open at the time that the locomotive is moving as the steam from the drifting valve passes through the superheater units when the throttle is open and when the locomotive drifts.

With arrangements *B* and *C* it is necessary, in addition to the drifting valve closing automatically with the stopping of the locomotive, that it close automatically with the opening of the throttle when the locomotive is moving in order to prevent delivering saturated steam to the cylinders with the *superheated* steam when the throttle is open. It is also necessary for the prevention of vacuum, for the drifting valve in the arrangements *B* and *C* to open automatically with the closing of the throttle and in time to maintain steam within the cylinders until the locomotive stops or the throttle is again opened.

The volume of steam necessary to prevent the creation of vacuum in the cylinders varies according to the diameter of the cylinders, the speed of the locomotive and the position of the reverse lever or point of steam cut-off, and will require approximately the use of a 1¼-in. pipe for 22-in. and smaller engines, a 1½-in. pipe for 23-in. to 26-in. engines, and a 2-in. pipe for 27-in. to 30-in. engines.

Advantages of Drifting Valves

It has long been recognized that manifold advantages, including the prevention of vacuum, are derived from the presence of steam in suitable quantity in the cylinders of a locomotive at all times when the locomotive is running above a very low speed, and that these advantages can be fully derived only through means to supply and cut off the steam automatically. A drifting valve which functions properly distributes and preserves the valve and cylinder oil, provides a steam cushion for the machinery, prolongs the life of the cylinders, pistons and rod and cylinder packings, protects the superheater units and prevents the loss of high cylinder temperature when drifting and results in increased locomotive mileage, decreased maintenance cost, higher average power, and increased mileage per unit of lubricant.

Looking Up the Machine Side of the Boiler Shop, Canadian Pacific Angus Shops, Montreal

TAKING UP THE SLACK IN PRODUCTION

How Causes of Lost Time on Unit Operations are Located and Removed at the C.P.R. Angus Shops

BY E. T. SPIDY

Production Engineer, Canadian Pacific, Montreal, Que.

THE functions of production may be divided into two classes: first, those which devolve upon the management, and second, those for which the workman is responsible.

In the first class are the duties of the supervisory staff to handle all orders, get the proper material to the workmen, plan the work in order that the desired output is obtained, provide the workmen with proper tools, keep the machinery in order, see that each operation is performed at the right machine, provide suitable workmen for each machine, and so on. These functions are performed by the foremen alone in small shops, or by an increasing number of specialist supervisors, each attending to one function only, in large organizations.

The rate at which the actual work is done by the workman depends entirely on the skill and knowledge of the individual only when the functions of the supervising organization have all been performed properly.

The question is, how do we know whether all these functions are being performed properly? Do we know what output we are getting from each workman compared with what he should produce? What is the reason for the failure to get full output from each man? What action is taken when we do know the reason for these failures? No one will say that these are not vital questions, yet, how many railroad shops have any definite system by means of which they can determine the answers with any degree of accuracy?

These are days when material is hard to get. Conditions are different from any previously experienced and good men are exceedingly scarce. Wages are so high that our old conceptions of what a job should cost are worthless. It is obviously our duty, not only to the railroads but also to ourselves as citizens who realize that idleness expense—which is what inefficiency really means—can only add to the growing

cost of living, to reduce this idleness expense by first finding out where it is and then applying the best available remedy. If we know where it is something can be done.

The methods of accurately determining the answers to the above questions which are described below are not new. They have been developed by a number of industrial engineers and applied in various ways to meet varying local conditions. In some shops the production department looks after them, in others the foreman himself has a man detailed for the work and supervises it personally. The process of checking up the details of production in a few departments will clearly develop the system.

It may be assumed that something appears to be wrong with milling machine production. A man who has the status of an assistant foreman is sent to that department with instructions to keep an accurate record of all the work being done by these machines. He records the time when each job starts and when it finishes. He is on the spot constantly and notes every time the workman is delayed. He is looking for the delays, and as soon as one occurs he notifies the shop foreman, the tool foreman if it is a tool failure, or whoever should apply a remedy. The record of these delays and the amount of time lost is retained for the purpose of compiling the summary records described later. As each job is started he ascertains the time it should take and notes this for comparison with the actual time taken. The time which should be required may be taken from piecework schedules which most shops have, even though not in use, or when no records are available, it may be estimated on the floor.

As soon as the time on a job has exceeded what we may call the allowed time for that job, lost output is obvious and the observer must account for the discrepancy, showing the reason on his record. He then notifies the foreman or supervisor responsible for correcting the faulty conditions as soon

as possible, and takes such action himself as is within his power.

Each day's performance is summarized on the special form shown in Fig. 1. Each sheet lasts for one week, and usually a record is kept continuously for two weeks in the one department, by which time usually the habitual delays of the department are fully apparent. In addition to those for which remedies may be applied immediately, there are often conditions requiring a change in policy which take some time to put into effect. These are discussed by the supervisors concerned, and the necessary consent having been obtained from the higher officers, are put into effect as soon as possible. Later on an-

X—Reason Not Clear.—Used when it is believed that the man is not to blame and conditions are good.

D—Defective Work.—Sometimes a defective piece of work requires special care that makes a delay. This account is up to the shop foreman to regulate.

M—Defective Material.—Used when the delay is creditable to defects in the material itself. Troubles from this source are referred to the test department or to the purchasing department.

W—No Work.—If no job is available when a man finishes the job in hand, the time lost in hunting up the foreman to get one is charged here. The extent of losses on this account are an indication of poor management in most cases, although it may be due to lack of orders, in which case the man must be disposed of on other work or laid off.

L—Lack of Instructions.—Used when delays occur due to lack of information or instructions of any kind, such as no drawings or sizes, which any supervisor has to supply.

P—Power House.—If compressed air, steam, water or any other power supply goes off it is recorded under this heading. This item is usually up to the power house engineer.

R—Repairs.—Used when the machine is placed under repairs, because of breakdown, changes or any other reason, when there is work available. The shop engineer is usually responsible for keeping this item down.

T—Tool trouble.—Failure to deliver output on account of defects, repairs to, or breakage of tools is up to the tool shop foreman to correct. Lack of a proper supply of tools and delays in getting them are also included in this account.

V—Shop Closed.—Used when vacations or any other shut downs occur, during which no output is expected.

Some delays cannot be overcome, but it is seldom that something cannot be done to prevent them from becoming of regular occurrence. Delays may often necessitate several supervisors getting together before a remedy is decided on, which always results in some future improvement being effected.

Referring to Fig. 1, it will be noted that the first man, Morris, turned out 60 per cent of a day's work on Monday, 70 per cent on Tuesday and better still each day; it was proved that there was no trouble for which he himself was not responsible. This is a common experience under this system. The second man, Poulet, was evidently an experienced operator, but had tool trouble on Tuesday. This proved to be accidental. The third man, Levesque, was a new man and unfamiliarity with the machine was responsible for his delays. These three men all operate the same machine on different shifts.

Deroches, the fourth man, is an efficient operator. Practically every day he turned out more than the allotted day's work, as indicated by the extra line. This, in a piecework shop, represents earnings over his wages.

The next three men each failed to give a day's work on account of tool trouble. This trouble was so apparent and consistent that it led to an investigation which showed the necessity of making a change in policy. It was found that owing to war exigencies this machine was equipped with carbon steel cutters. It was proved conclusively that high-speed cutters were required to reduce the expense of the work, and instructions were issued for this change to be made as soon as possible. Incidental to this, a change in design was found desirable. It was shown in experiments made later that by using a high-speed cutter of larger diameter and shorter length better time was made milling around links and such work singly instead of doing two at a time. Two pieces at a time produced too heavy a load for the machine.

Items 8, 9 and 10 show the performance of a machine run by apprentices. This was not very good, and on Thursday it will be seen that the machine broke down and one apprentice was transferred to the last machine on the sheet, where there was a vacancy on the third shift.

It will be obvious that a chart of this nature tells the whole story of shop output and troubles. The expense of getting it is negligible compared with the value of a knowledge of all the facts and the ability to place them before the right parties—the only way to ensure better results.

A summary of Fig. 1 shows that there were 704 machine hours available for production. Summarizing the delays, it will be seen that 236 machine hours have been lost for various reasons, a loss of 33.3 per cent for the week. These losses are chargeable as follows:

CANADIAN PACIFIC RAILWAY		ANGUS SHOPS							DEPT. MACHINE SHOP

16. ALEGRE	3	70%	70%	70%	70%	70%	70%	704	704	
								TOTAL MACHINE HOURS	704	
								MAJOR LOSS	236	
								70.4 PER CENT	33.3	

Fig. 1.—Chart Showing Results of a Detail Study of Milling Machine Operation

other department check is made to determine whether the improvements have had the desired effect and whether there are any further controllable delays.

The heading of the form states its purpose. A column is provided for each day of the week, and each day is subdivided into hours to facilitate entries. Each day's record is distinct and not combined with the next day in any way. When work runs into the next day, as it often does, the entry is not made until the job is completed, and then the percentage efficiency is prorated for each day. Horizontally, 100 per cent output is represented by the distance between the day columns, which on the actual form is one inch. If the operator gives only six hours' output in eight hours a thick black line is drawn in the space for the day equal to 6/8 of its width. The remaining space represents lost output and in it is placed a symbol letter or sign indicating the reason for the loss.

For convenience and uniformity a standard set of symbols is used which covers all delays in a general way. These are supplemented when necessary in certain departments to show special conditions. They are as follows:

A—Man Absent.—Used when there is available work, and a workman assigned to the job who is absent for any reason. This calls for the foreman to investigate causes and to discipline the absentee when necessary.

H—Lack of Help.—Used when there is work at the machine and no men available. More men are usually required if this appears frequently.

N—New Man.—Used to denote that the delay is caused by a new workman who is not yet familiar with the work. Such a man is expected to make good in a short time. This may call for instruction by the foreman.

O—Up to the Man.—Used when there is reason to believe that all conditions are favorable and the workman could himself prevent the lost time. Consistent delays on this account indicate that the man should be replaced.

	Hours	Per Cent of available hours
R—Machinery repairs	49	7.0
T—Tool trouble	63	8.9
N—New Men	10	1.3
O—Lack of skill	61	8.6
A—Men Absent	20	2.8
H—Lack of help	24	3.4
X—Reason not clear	3	.4
L—Instructions	6	.9

By presenting the responsible supervisors concerned with data of this nature they all realize that a measure of their efficiency is in the hands of the management, on which fair judgments can be based.

The reason for the delays is always insisted on, and shifting responsibility is of no use because the other man will refuse to accept what is not his due. On the workman's part he realizes that a continued bad showing surely will result in his transfer to inferior work, or worse.

Fig. 2 shows another of these forms on which is recorded a specific condition. Having a large amount of boiler work on hand and not being satisfied with the output, it was determined to learn the reason for what was considered an excessive amount of time required for each engine.

The department, it will be noted, is operating two shifts,

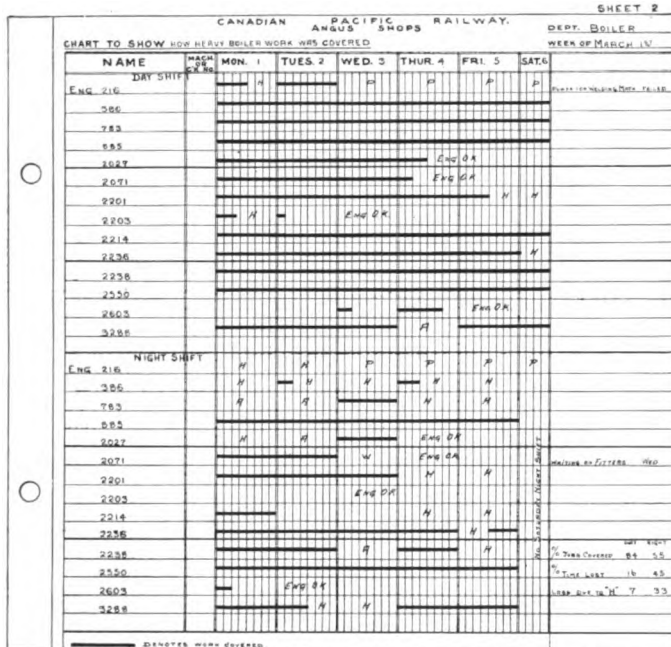

Fig. 2.—Chart Showing the Effect of Insufficient Help on Heavy Boiler Work

and the top half of the chart is devoted to the day gang, while the lower half covers the same engines on the night gang. On this chart is being checked how the work is covered by the workmen, to determine the reason why no workmen are on a job when the work is available. In this case spaces representing time with no boiler work scheduled are left blank.

This chart shows very plainly that the boiler shop foreman is confronted with more work than he has men to cover. It shows also that he has much trouble with absentees. The lack of uniformity of the lines on the chart shows that despite all planning to cover work, on account of the absentees and shortage of men he is switching his men from one place to another to make the best use of them.

A few other reasons for delays requiring investigation are to be seen on this chart. Delays marked W prove that the fitters are not through when the boilermakers arrive to make the test, which indicates the weak point.

The chart shown in Fig. 3 looks altogether different from the others, showing few delays and in general all operators making good. This indicates what a good chart should look

like, although it might be still better. There are features which should be looked into, such as to be sure that the shop is not overstaffed with non-producers, but it reflects good management by its obvious lack of lost time. This shop is a manufacturing department and is not subject to such quick changes and short-time jobs as the others. It should not, of course, be judged on exactly the same terms.

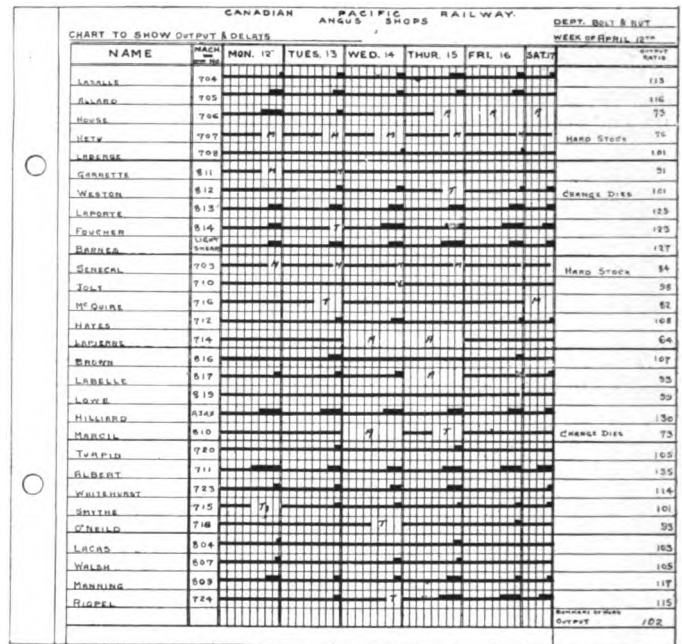

Fig. 3.—A Chart Taken in a Manufacturing Department

Fig. 4 shows a form on which the details are recorded by the checker. Each job is entered as it is started and is filled in as the work progresses. Delays are usually entered on the line below, with reasons in detail.

This system is independent of any other system in the shop, and it does not matter whether it is a daywork or piecework

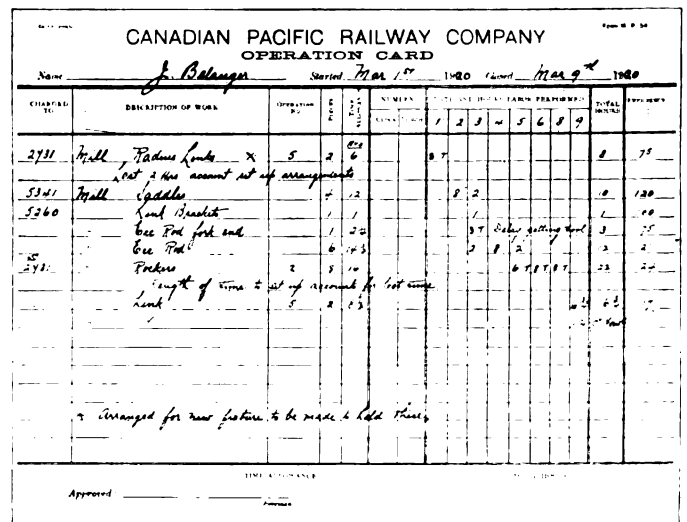

Fig. 4.—Form of Record Sheet Used in Making Detail Studies of Delays

shop. It has no connection with the shop schedule or routing system, although it shows up defects in them if work is delayed. It can be adapted to show special conditions, as pointed out in Fig. 2. By reducing lost time to a minimum a greater output may reasonably be expected, and such results have actually been obtained.

AIR CONSUMPTION OF LOCOMOTIVE AUXILIARIES*

Cost of Wasted Air Shown and Condemning Limits Proposed to Raise Standard of Maintenance

THE subject of pneumatically operated auxiliary devices† on locomotives was assigned to a committee after the meeting of the Association at Cleveland, May, 1918. The committee presented a report of progress at the last meeting and was continued for the following purposes:

- (1) To obtain more complete and representative data concerning the air consumption of locomotive auxiliary devices.
- (2) To obtain data for comparing the performance of metallic versus non-metallic packing in reverse gears.
- (3) To devise a satisfactory method for testing auxiliary devices on locomotives.
- (4) To submit a suitable test code for testing auxiliary devices on locomotives.
- (5) To suggest and recommend suitable limits for rates of air consumption of auxiliary devices to serve as a maintenance standard and to condemn defective devices out of service.

The larger portion of the data collected and analyzed by the committee were in connection with standing tests, i. e., tests made to determine the rate of air consumption of auxiliary devices with the locomotive standing in the roundhouse. A total of 497 such tests were made on as many devices. These tests involved 111 locomotives as found on 12 railroad systems. It was necessary in every case to convert the results obtained on the test basis of 60 lb. air pressure to a basis of 100 lb., the nominal main reservoir pressure so widely used in freight service.

The first work done was to devise a method of test and prepare a suitable test code so that it would be possible to direct the making of the standing tests at different localities in a systematic and uniform manner. The test code was sent out to about 30 members, with a request that standing tests be made of all kinds of auxiliary devices in use. In every case where the recipients were able to comply with this request, a number of tests were made in strict accordance with the code, and no special difficulties were reported either in following out the method of making the tests or in computing the results.

With this code the committee sent out a tentative set of condemning limits which were arbitrarily chosen in an attempt to compromise between the degree of perfection possible to attain on the one hand and what might be regarded as excessive maintenance costs on the other hand. All the standing test data has been referred to these limits elsewhere in this report, and while this comparison shows that they would condemn a very large percentage of the devices tested, no change in the limit basis is thereby justified. It should be borne in mind that the devices tested were taken as found in service where no accurate or reliable provisions for their maintenance were in force. Under conditions of systematic maintenance much better results would be obtained and it is not improbable that the limits here suggested could be materially reduced before passing the point of diminishing returns on maintenance investment. This, of course, is a matter which will be dictated by future experience.

The Standing Tests

The only test apparatus necessary for making the leakage rate tests specified in the code is an orifice holder with suitable orifice discs, and a test gage.

The orifice holder may be a flat lipped union pipe fitting suitable for holding the orifice disc and the necessary pipe connection for attaching it to the drain cock or any other

suitable connection to the main reservoir. The orifice disc at the orifice should be 1/16 in. thick and the hole should be accurately bored, (not drilled) with sharp edges. The rim of the discs may be somewhat thicker to give strength, but the thicker part should not come nearer at any point than 3/16 in. to the orifice itself. It is preferable to make the orifice out of hard brass, bronze or monel metal. The test gage should be installed so that it will indicate the main reservoir pressure. It is not absolutely necessary because the regular brake equipment gage in the locomotive cab can be used. Any inaccuracy in the gage employed is eliminated,

TABLE I—FORM FOR THE TABULATION AND COMPUTATION OF TEST RESULTS

Ioco. No.	Class.	Div.	Date.
	Compressor type and orifice diameter		
METHOD:			
Throttle compressor steam valve until 60 lb. air pressure is just maintained in main reservoir. Count compressor speed in single strokes per minute.	Make and size of compressor	Dia. of orifice, in.	Air press., lb.
West., 9½ in.		11-64	60
West., 11 in.		3-16	60
West., 8½ in. C. C.		9-32	60
N. Y., 2-a		5-32	60
N. Y., 6-a		13-64	60
N. Y., 5-b		15-64	60

(Orifices are the same as used for I. C. C. compressor condemning tests).

1	TESTS			COMPUTATION OF RESULTS		
	Leakage only* 2	Lkg. plus orifice* 3	Lkg. plus device 4	Orifice only 5	Device only 6	Per cent of strokes. Col. 6, col. 5 7

NOTE:

(a) Where the locomotive is equipped with two compressors the counting of compressor strokes will be easier if one compressor is cut out.

(b) Where the leakage is so slight that it is difficult to accurately count the compressor strokes it is permissible to create a leak to increase compressor speed provided it is left unchanged during all three tests.

(c) Where the locomotive is equipped with an auxiliary device reservoir and governor it will be necessary to remove the auxiliary devices governor main valve while tests are being made.

*Cols. 2 and 3 give single observation for all tests as leakage and orifice are constant for all tests.

Col. 5 is the difference between cols. 3 and 2.
Col. 6 is the difference between cols. 4 and 2.
Col. 7 is col. 6 divided by col. 5.

provided the test comparison is always made at the same pressure. This is because the nature of the test is to compare the flow of air due to leakage with that through a known orifice.

The determination of the leakage rate for each auxiliary device tested will depend on the results of three tests. However, two of these tests will always be common to all devices tested on the same locomotive, so that after the first device is tested only one test will be required for each succeeding device tested on that locomotive. The methods of making the tests and the computation of results are briefly outlined in Table I, which shows a convenient form for recording the data.

In making the tests, close the compressor steam throttle valve, cut out the main reservoir supply to all air operated

*Abstract of a committee report and discussion, presented at the twenty-seventh annual convention of the Air Brake Association, held at Chicago, May 4-7, 1920.

†The term "air operated auxiliary devices" as used in this report refers to all air operated devices on locomotives which are not a part of the air brake system.

auxiliary devices, and see that the drain-cock at the orifice fitting is closed. Reduce main reservoir air pressure down to some value lower than 60 lb., preferably about 55 lb. Open the compressor throttle slowly until the compressor raises the main reservoir pressure and is just able to maintain it at 60 lb. When this condition has been reached for a time of about three minutes so that the tester can be sure that a true balance of the pressures has been obtained, the compressor speed in single strokes per minute will be counted. The count will be entered in column 2, under the heading "Leakage only."

The second test will be made in the same manner except that the drain cock leading to the orifice will be open. This will mean that in addition to the leakage, the compressor will have to maintain the main reservoir pressure at 60 lb. against the air passing to atmosphere through the orifice. Enter the compressor speed in column 3, which is headed "Leakage plus orifice."

The third test will be made in the same manner as the first and second tests except that the orifice fitting will be cut out and the particular auxiliary device to be tested will be cut in. The compressor speed will be entered in column 4, headed "Leakage plus device."

The computations are clearly indicated on the form and the final comparison for each device is expressed in per cent of strokes per minute required to supply the orifice.

Condemning Limits

It will be observed that the type of compressor with which the locomotive is equipped will determine the size of the orifice used. The orifice sizes chosen are the same as those

TABLE II—LIMITS RECOMMENDED FOR CONDEMNING AIR OPERATED AUXILIARY DEVICES ON LOCOMOTIVES

Device	Percentage of orifice strokes allowed					
	9 1/2 in. comp., 11/64 in. orifice	11 in. comp., 3/16 in. orifice	8 1/2 in. C. C. comp., 9/32 in. orifice	2-a comp., 5/32 in. orifice	6-a comp., 13/64 in. orifice	5-b comp., 15/64 in. orifice

specified by the well known Interstate Commerce Commission compressor condemning tests and can, therefore, be used for testing both compressors and auxiliary devices. These orifices and a suitable orifice fitting are always available at roundhouses and other places where the compressor tests are made.

Table II gives the limiting values of percentages as computed in column 7 of the previous table. A value is given

TABLE III—AIR CONSUMPTION EQUIVALENT TO THE CONDEMNING LIMITS Leakage rate in cubic feet of free air per minute

Device	Leakage rate in cubic feet of free air per minute		
	At 60 lb. pressure	At 100 lb. pressure	At 140 lb. pressure
Bell ringers	3	4.6	6.2
Fire doors	5	7.7	10.3
Cylinder cocks	10	15.3	20.7
Reverse gears	10	15.3	20.7
Sander (per each 3/32-in. nozzle).....	10	15.3	20.7
Ash pan	15	23.0	31.0
Water scoops	20	30.7	41.3
Coal pushers	20	30.7	41.3

for each kind of auxiliary device when tested under the six different combinations of compressor and orifice size. Whenever the percentage of strokes found in column 7, Table I,

exceeds the corresponding value given in Table II, the device in question should be condemned and ordered for necessary repairs.

The leakage rates in cu. ft. of free air per minute equivalent to the condemning limits suggested above are shown in Table III.

The results of the standing test data are shown plotted in a convenient form in Fig. 1. The average maximum and minimum values for leakage are given for each condition under which the various devices were tested, and it is shown on the basis of 100 lb. main reservoir pressure. The corresponding test code leakage limit value is also shown for each device. The data shown are the most complete informa-

Fig. 1—Air Consumption of Auxiliary Devices of Locomotives Determined from Tests of 111 Engines

tion of its kind in existence and can be regarded as a true index to the general condition and performance of auxiliary devices.

Table IV gives the result of applying the recommended condemning limits on all devices tested, more than half of which would thereby be condemned.

TABLE IV—EFFECT OF APPLYING CONDEMNING LIMITS TO THE DEVICES TESTED

Running Tests of Power Reverse Gears

To determine the air consumption rate for reverse gears when running in service, a very complete program of tests covering a period of about five weeks' work was outlined. It was impossible to carry out the program fully, but service runs were made with 21 locomotives which were distributed

on four divisions of three railroads. The data for these tests are shown in Table V.

The curves for three tests are plotted in Fig. 2. These curves represent respectively the worst gear tested, the best gear tested and the retest of the worst gear after it had been repaired to correct the leakage.

It will be noted that the tests included 15 gears having metallic packing and 6 gears with non-metallic packing. The tests were made without any special regard for either type of packing and show a distinct difference in the quality of service in favor of the metallic packing. This is evident from the average miles of service per cu. ft. of average leakage developed. The figures show that where the non-metallic packed gears made 249 miles for each cu. ft. per

economical condition. They undoubtedly perform the intended functions in a very satisfactory manner, but only at the cost of compressed air. This cost is much greater than it need be, and the problem of reducing it to a minimum resolves itself into the determination of how much maintenance expense will be warranted. The test figures show a wide field for profitable investment in maintenance, and better maintenance will carry with it other betterments, such as less wear and tear, more perfect performance, and greater reliability, all of which will tend to turn to raise the efficiency of locomotive operation. The proposed condemning limits will serve to reduce the waste at least one-half, and when this saving is accomplished the association will be in a position to scale the limits downward on a scientific basis,

Fig. 2—Air Consumption Curves for Power Reverse Gears on Freight Locomotives in Road Service

min. leakage developed the metallic packed gears made 2,491 miles, a ratio of just 10 to 1 in favor of metallic packing. The number of gears tested, however, is not sufficient to warrant final conclusions.

The Field for Profitable Maintenance

The general aspect of all the test results indicates that the air operated auxiliary devices are in a more or less un-

because it will then have available actual maintenance cost figures.

The committee fully realized the importance of attacking this subject on a cost basis, but certain necessary service factors remain to be determined in a more accurate and reliable manner before such comparisons could be justified. A knowledge of maintenance costs would also be necessary to a complete analysis of the costs involved.

TABLE V—SUMMARY OF REVERSE GEAR RUNNING TESTS
(Leakage based on 100 lb. main reservoir pressure.)

Locomotive	Type of ragonnet reverse gear	Kind of packing	Leakage, cu. ft. free air per min.			Total cu. ft. free air used during trip	Mileage from application of packing to date of test	Miles per cu. ft. per min. average leakage

S	"	"	21.5	2.8	17.1	3356.4	26,487	1548	
T	"	"	5.6	1.8	3.7	886.6	32,007	8594	
U	"	"	32.9	1.8	18.7	2776.8	16,678	891.3	

However, some of the facts demonstrated by the data have an important bearing on how much it is costing the railroads to operate auxiliary devices as compared to what it really ought to cost. In other words, it is possible to point out, on the basis of compressed air used, the probable margin of saving that could be effected by a reasonable maintenance program, from which it is comparatively easy to decide how much maintenance expense is warranted.

The data presented in Fig. 1 cover all the different kinds of devices tested. It is not permissible to base a comparison on all of the devices listed because several of them are not subject to constant use while the engine is in service. For the purpose of this comparison only three kinds of devices are chosen; namely, bell ringers, fire doors and reverse gears. It is assumed that the respective average rates of air consumption found for these three devices in the standing tests are characteristic of their average condition in service.

It can also be assumed that if these devices were maintained within the maximum rates of air consumption fixed by the test code limits the average leakage could be held to not more than one-half that represented by the limits. The actual figures for such a comparison are given in Table VI.

TABLE VI—ACTUAL AND POSSIBLE RATES OF AIR CONSUMPTION OF BELL RINGERS, FIRE DOORS AND REVERSE GEARS.

	Average-rate in cu. ft. per min. at 100 lb. main reservoir pressure. Actually found during tests		Insured by test code limits
103 Bell ringers.....	7.75		2.30
107 Fire doors.....	6.80		3.80
68 Reverse gears.....	16.57		7.60
Totals	31.12		13.70

It will be evident from the above table that locomotives equipped with the three devices listed would supply 31.12 cu. ft. of free air per minute to operate these devices, whereas if the devices were maintained within the test code limits the air requirement would only be 13.70 cu. ft. of free air per minute. This difference is decidedly impressive when

Fig. 3—Annual Cost of Compressed Air Used by Three Auxiliaries and the Portable Cost Under Proposed Condemning Limits

expressed in terms of the money value of compressed air. Such a comparison is shown in graphic form by Fig. 3. The cost values were computed from the data by using the following assumptions, which are commonly accepted as conservative for the factors involved:

1. That the average working time for locomotives is 6 hours per day or 2,190 hours per year.
2. That the average evaporation rate for locomotives will be seven pounds of water per pound of coal.
3. That the rate of steam consumption per 100 cu. ft. of free air compressed to 100 lb. pressure will be for the 9 1/2-in. and 11-in. compressor, 68 lb.; for the 5-A compressor, 44.7 lb.; for the 8 1/2-in. C. C. compressor, 24 lb.; based on actual steam consumption tests.
4. That the price of coal on the tender is \$2.00 per ton.

The two extremes of the comparison in Fig. 3 can be pointed out as follows:

1. On basis of 100 locomotives having 8 1/2 in. C. C. compressors, the cost per year without maintenance would be \$14,000, and with maintenance, \$6,170, leaving a margin of \$7,830 for reduction of expense.

2. On basis of 100 locomotives having 11 in. compressors, the cost per year without maintenance would be \$39,700, and with maintenance, \$17,480, leaving a margin of \$22,220 for reduction of expense.

The assumption of coal cost as \$2 per ton on the tender is much too low to represent the actual average cost of coal. The reason this value was taken was to make it easy to convert the cost figures to correspond to any price paid for coal. It would not be unreasonable to contend that the average cost of coal on the tender is about \$5 per ton, and in such event the costs and margin for economy would be two and one-half times greater than those given in Fig. 3. Likewise, it should be remembered that these figures are based on only three devices, all the others being ignored, although many locomotives have them. Those devices are, therefore, an additional source of compressed air waste, which was omitted in this comparison because no accurate data were available, and because its omission is in the direction of making the cost values more conservative. Other cost increasing factors, such as wear and tear on the compressor plant, cost of water, labor, etc., were also omitted, because exact data were lacking.

Discussion

It was very evident from the discussion of this report that few of the members of the Air Brake Association have realized the seriousness of the losses from air leakage in connection with the operation of auxiliary devices on locomotives as they are generally maintained. Some of the members, who had applied the tests recommended by the committee for the purpose of securing data to be used in the preparation of the report, testified as to their efficacy in bringing to light conditions causing excessive air consumption, which might otherwise continue indefinitely so long as the apparatus functions without positive failure. No objections were raised as to the practicability of the tests themselves, their simplicity and the ease with which inspectors may be trained to make them being commented on generally by those who have already tried them out. There was some difference of opinion, however, as to the proper time and intervals for their application. The committee offered no recommendation on this point, but left it to be worked out by the members as individual conditions and experience might dictate.

In discussing the cost of excessive leakage, the committee considered only those devices which are usually under constant pressure. It was brought out in the discussion that, while devices such as water scoops do not cause a serious waste of air in the aggregate because of their infrequent operation, they do draw heavily on the air supply when operating, and when neglected, excessive leakage may result in undesired applications of the brakes or inability to release the brakes, so that from this standpoint their maintenance is of equally as great importance as that of the more frequently operated devices.

The committee was continued to report at the next convention what progress has been made in establishing the tests and to what extent they have led to improved conditions. A suggestion was also offered to the executive committee that measures be taken to bring the paper to the attention of the American Railroad Association, Section III-Mechanical.

COOLING COMPOUNDS FOR CUTTER SHARPENING.—The cooling compound for wet grinding is a question on which there is considerable difference of opinion. Water is about as good a coolant as can be obtained, but it has the disadvantage of rusting the moving members of the machine. A cooling compound which has been used with good results is soda water. This comprises one pint of sal soda to 10 quarts of water. The solution is mixed cold and applied in the usual manner.—Grits and Grinds.

MACHINE TOOL

AND

SHOP EQUIPMENT

SECTION

High Power Multispeed Planing Machine

MECHANICAL engineers conversant with machine tool design recognize that the real problem to be solved in planer construction lies in overcoming the inertia of the high-speed parts, which may reach a value many times that of the massive table loaded with work. This inertia must naturally all be absorbed by the belts or motor at the moment of reversing. In the planing machine, illus-

this shaft meshes with the forward clutch gear, thereby giving four cutting speeds.

In order to provide a smooth, durable reversing mechanism, a special form of annular pneumatic clutch has been adopted, as this type is self-compensating for wear and requires practically no attention. Dogs on the platen trip the distributing valve, alternately admitting air to one or the other of the clutches. As a spacing rod connects the two, one is forced out when the air is admitted to the other, making it impossible to lock the drive gearing. The reversing of the clutch shaft is accomplished in this manner. The back gears, bull pinion, bull wheel, and rack are of herringbone design. This method of driving has been adopted, as it is difficult to build a machine with spur or spiral gearing that, for any length of time, will be free from showing a tooth mark. The chief advantages of herringbone rack and gear drive are continuous smooth operation, greater resistance to wear, reduction of back lash, and increased strength of the teeth. All gears and bearings are automatically oiled by the splash system, and the overflow of lubricant returns to a central tank by gravity.

The planer bed is of box section type, thoroughly reinforced. The wide supporting surface of each V is inclined 15 degrees to the horizontal, permitting the formation of a uniform oil film under the most severe conditions. The inner leg is inclined 15 degrees to the perpendicular, functioning as a guideway. The proportioning of the two is such that the wear is self-compensating. The pockets for lubricating

View Showing Motor Drive Arrangement

trated, high-speed reversing parts have been entirely eliminated, thereby greatly reducing the wear and tear as well as the power required for reversing.

It is essential that an efficient planer furnish the various speeds and feeds for different materials, as well as a constant return of the platen. Four speeds, therefore, are provided and a constant quick return which is independent of the

Ryerson-Conradson Planer With Pneumatic Feeds and Reversing Clutch

cutting speeds. For general machine shop work, cutting speeds of 25, 30, 37½ and 45 ft. per min. are provided in the heavier types, with a return speed of 100 ft. per min., all of which may be varied to suit requirements.

The motor is directly connected to the main drive shaft by a Clark flexible coupling. The primary shaft carries two-spool gears, and on the extreme end of this shaft the reversing pinion engages directly with the return clutch gear. The change gears are mounted on a square shaft and are shifted by a lever mounted in a gridiron. The pinion on

the ways are automatically filled with the oil carried up by the bull wheel. Each end of the bed carries a large apron extending beyond the maximum travel of the table for catching all surplus oil which, after filtering, returns to the central tank by gravity.

The driving mechanism of the rack feed constitutes a departure from customary practice. A piston, operated pneumatically turns the feed regulating disk through 180 degrees, the crank of the disk being connected with levers to a gear segment, raising and lowering the feed rack. The moment

the table trips the air distributing valve, air is admitted alternately to one of the clutches as well as the corresponding end of the rack feed piston.

The cross rail elevating screws are driven by a motor mounted on a cross girth, the entire elevating mechanism consisting of spur reduction gears and a set of bevel gears, the latter placed directly on the elevating screw. The cross rail is of standard construction, permitting individual traverse and feed of each head in either direction. The heads on the cross rail and both side heads have power angular feed and are of extra heavy design. The side heads have power vertical traverse the full length of travel, and also power feed at any angle.

To operate the clutches and rack feed piston, compressed air is required, the pressure recommended being 80 to 100 lb. per sq. in. The air consumption of the planer is exceptionally low, ranging from 3 to 10 cu. ft. of free air per min. from the smallest to the largest size planer. For shops not having a compressed air system, suitable means are provided for connecting a small standard compressor directly to the main drive shaft.

The planer described can be furnished in four sizes from 24 in. by 24 in. to 48 in. by 48 in. Driving motors varying from 3 hp. to 25 hp. are required, depending on the character of the work to be done. The machines have been placed on the market by Joseph T. Ryerson & Son, Chicago, Ill.

Automatic Chucking and Turning Machine

A NEW automatic chucking and turning machine, called the 8-B, has been developed by the Potter & Johnston Machine Company, Pawtucket, R. I. It is built with a geared automatic change speed head, and the spindle driving mechanism is all contained in the headstock, which is of unit construction. The machines are heavy, powerful and accurate, well suited to the manufacturing of multiple parts as in modern railway shops. The drive is by a single pulley transmitting 20 hp.

Four combinations of six automatic variations of speed are available, giving 24 spindle speeds in geometric pro-

of feeds may be doubled. The hand changes for the feeds are obtained by means of tumbler levers, conveniently located at the front of the machine. The ratio of the second feed to the first feed is constant. The third feed is independent of the first two, and any desired combination may be obtained. The changes obtainable on the machine give the proper lead for cutting from 20 to four threads per inch, using automatic collapsing taps or automatic opening die heads. Any one of the three feeds can be obtained automatically at any time. The feeds are independent of the high constant speed for idle movements of the turret slide

Potter & Johnston No. 8-B Manufacturing Automatic

gression from 6 r.p.m. to 92.5 r.p.m. Any one of these combinations may be instantly obtained by levers conveniently located on the headstock. The gearing for driving the spindle is self-contained within the headstock, all gears running in oil, which is pumped through all bearings. A gear on the spindle takes care of the higher spindle speeds, while the lower ones are taken care of by a gear fastened to the chuck or face plate.

The feed gearing is driven from the spindle. There are seven combinations of three automatic variations of feed, making a total of 21 feeds from .005 in. to .125 in. per revolution of the spindle. By changing one train of gears conveniently located on the outside of the machine, the range

while withdrawing, revolving and advancing the tools to the point of cutting.

The cross slide is provided with front and rear blocks and two pairs of tool posts are furnished with each machine. The front and rear cross slide operate independently by screw feed, having a feed of 10 in. and can be arranged to feed into the work at any predetermined time, and at any desired relation, one to the other. The turret slide is of rugged construction and travels on ways so designed that all wear will be even and will not affect the accuracy of the machine. The turret slide has a 28-in. feed and no allowance needs to be made for revolving, as the turret revolves at the extreme end of its travel. It has 13-in. lon-

itudinal adjustment by means of a hand crank and is securely clamped in any desired position by three bolts, besides being located by the adjusting screw.

The turret has four stations upon which tools may be mounted, and with each machine an outfit of turret turning tool holders, stems and cutters is furnished. Turrets with five or six faces may be furnished if desired. The turret is revolved by power through an intermittent pinion

All operation of the speed clutches, feed and quick return clutches is done by a patented method, operated by dogs located on the dog wheel or drum. This method gives instantaneous movement to the clutches and enables the feed, speed and quick return to begin at exactly the same place each time. An oil pump and piping and oil arrangement through the turret are furnished on machines handling material requiring a lubricant. A 24-in. three-jaw

Rear View Showing Cutting Lubricant and Oiling Systems

and gear and is so designed as to give an easy stop and start, the turret being stopped when the lock bolt engages, thus removing any shock from the lock bolt. It is clamped into position by a powerful binder working on the largest diameter of the turret seat. Levers are conveniently placed to release the binder and lock the bolt so that the turret can be revolved by hand. Both cross and turret slides are adjusted in relation to each other by conveniently placed clutches.

geared scroll chuck regularly accompanies the machine and is furnished with standard set of jaws and wrench. The chuck is provided with pilot bushings to receive pilot bars for supporting the tools during the cutting operation.

A swing of 35 in. is possible over the machine bed and 24 in. over the cross slide. The travel of the cross slide (front and rear separate) is 10 in. A 15-hp. motor is required to drive the machine, when motor driven.

Universal Index Centers With 10-In. Swing

A UNIVERSAL index center made to swing work up to 10 in. in diameter has been placed on the market recently by the Simmons Machine Company, Albany, N. Y. This index center is shown in Fig. 1 with two extra

regularly furnished with tongues $\frac{5}{8}$ in. wide, but any width of tongue may be specified. The equipment includes three index plates, four $\frac{5}{8}$ -in. bolts, wrenches and an index chart.

If desired, the index center can be provided with a spiral

Fig. 1—Simmons 10-In. Universal Index Center

index plates in the foreground. The spindle has a No. 10 B. & S. taper. The swivel block is graduated and the worm wheel diameter is five inches. The head and tailstock are

Fig. 2—Universal Index Center With Spiral Cutting Attachment

cutting attachment illustrated in Fig. 2. By removing the extension arm, the head can be swung 90 deg. The front end is threaded 2 $\frac{5}{16}$ in., and has a 1 $\frac{1}{16}$ in. hole through

the entire length. The index crank is adjustable and all bushings are hardened. The gears are $\frac{3}{4}$ in. thick and have $1\frac{1}{4}$ -in. bores. The equipment furnished is the same as

previously mentioned. The Simmons dividing heads or index centers may be used on any standard milling machine adapted to tool room work.

Air Operated Combination Three-Jaw Chucks

THERE is undoubtedly a big field for the use of air operated chucks in railway machine shops, especially those that have been modernized and placed on a production basis. Probably the most useful application at the present time is to turret lathes, and Fig. 1 shows a three-jaw,

the spindle is evenly balanced and the overhang is reduced to a minimum. The one-piece body construction gives ample strength. The improved jaw operating mechanism reduces friction and wear and insures a positive grip on the work that will hold under severe cuts and feeds. Dustproof joints

Fig. 1—Logan 24-in. Air Operated Chuck Applied to Heavy Duty Turret Lathe

air operated chuck thus applied. This chuck holds the work more securely than one operated by hand, which makes possible heavier cuts and increased feeds. There is also a

between the draw tube and jaw slide keep dust and chips from working into the operating mechanism.

The combination three-jaw chuck, illustrated in Fig. 2, is provided with jaws which are adjustable and reversible. They can be set independently by a wrench or universally

Fig. 2—Cross Section of Combination Three-Jaw Chuck

big saving in chucking time and a resulting increase in production. The Logan chuck, illustrated, is being placed on the market by Frank E. Payson Company, Chicago, Ill., and is adapted to all types of lathes. The weight on

operated by compressed air in connection with the Logan double acting air cylinder. Master jaws with plain, soft steel blocks are regularly fitted to a steel or semi-steel body. A set of three-step reversible hardened steel jaws to fit the

Fig. 3—Logan Double Acting Air Cylinder

master jaw can be provided if required. Attention is called to the one-piece body construction, the convenient, adjusting screw, the chrome nickel steel lever, and the fact that the draw tube and jaw slide do not separate, making a dust proof joint.

A cross section of the double-acting air cylinder, Fig. 3, shows the Johns-Manville type of packing cup and expander ring. The general arrangement of the cylinder is indicated and it is stated that leaking in the air shaft, a prevalent trouble, particularly in high speed machines, has been entirely overcome. This cylinder can be used on a machine

running at a constant speed of 1,500 r. p. m. without overheating or requiring much attention. When the air is applied it enters an air channel between the outside of the piston and the inside of the expander ring, increasing the pressure against the cylinder bore and preventing air leakage.

The air valve is shown in Fig. 1 and consists of a semi-steel body with a hand-lapped bronze taper plug operated by the handle shown. The parts are easily accessible for oiling or cleaning without disconnecting air pipes. A reversible handle enables the valve to be located in any desired position on the machine.

A Powerful Vertical Type Milling Machine

FOR many kinds of work the vertical type milling machine has important advantages over the horizontal type. With this fact in mind, the Kempsmith Manufacturing Company, Milwaukee, Wis., has designed the No. 4 vertical Maximiller which embodies several of the features of the horizontal type Maximiller previously described in the March, 1919, *Railway Mechanical Engineer*.

Special attention paid to securing a rigid machine has reduced vibration to a minimum and the entire design has been made with a view to maximum power, convenience of operation and quality of work. The main frame members of the machine, including the column, knee, saddle and table, are of semi-steel, with every effort made to secure strength without adding more metal than necessary. The column has few and small openings. It is well ribbed and has a rib midway of the column height, forming a reservoir for the speed drive oil. This rib also has a stiffening effect on the column.

The design of the knee is the same as that used on the horizontal machine, and there is no opening at the top, merely

means of weights inside the column. Easy vertical adjustment of the work in relation to the cutter makes an auxiliary vertical slide for the spindle unnecessary. The table has a working surface of 70 in. by 18 in. and a longitudinal range of 42 in. Table wear is taken up on adjustable taper gibs with locked adjustment. Face milling cutters may be driven in either direction and the spindle nose construction permits cutters to be set up or removed easily. A spindle reverse has been incorporated for the reason that, in order to get cutting

View Showing Machine Arrangement for Motor Drive

a shallow depression to receive the center drive cross feed screw. The side walls also are practically solid, having but three small openings. This solid construction serves to resist clamping strains and the torsional effects of the table overhang. The knee, table and saddle are counterweighted by

Kempsmith No. 4 Vertical Type Maximiller

strains in the proper direction on the gibs and tables, a face mill must be run in the opposite direction to a spiral or slab mill. The spindle reverse of this machine is controlled by a single lever conveniently located.

The No. 4 Maximiller is arranged with power quick traverse, giving a 100-in. per min. travel of the table in either direction and a vertical movement of 36 in. per min. The traverse control is concentrated, and it is unnecessary for the operator to change his position in operating any of the quick traverse and feed movements. In case of error on the part of the operator in engaging wrong levers, the machine is amply protected by safety devices.

Eight changes of feed are provided, ranging from $\frac{5}{8}$ in. to 25 in. per min. in geometrical progression. The gears are all heat treated and proper safety devices are incorporated throughout to prevent exceeding the maximum safe load. Particular attention has been paid to the question of lubrication, and the gears and shafts in the entire speed and feed mechan-

ism run constantly in oil. The balance of the oiling system is centralized at two points, so that none will be overlooked. For the circulation of the proper amount of cooling compound, a pump of 15 gal. per min. capacity has been provided.

A change in the power quick traverse rate does not affect the speed rate of the cross and vertical movements, and the quick traverse is available even if the spindle and feed are not operating. This is an advantage when setting up the machine or in returning the table after a completed cut has been taken. The machine is regularly arranged for single-pulley drive, but at an additional cost it can be arranged for

motor drive through a belt, in which case a 15 h.p. motor, running at 1,200 r.p.m., is required.

The longitudinal, transverse and vertical ranges are 42 in., 14 in. and 20 in., respectively. The distance from the spindle to the table, in the lowest position, is 22 in. and the throat distance is 19 in. There are 18 spindle speeds, ranging from 14 to 355 r.p.m. Eighteen feeds are provided, which range from $\frac{5}{8}$ to 25 in. per min. Owing to the power and convenience of operation of the No. 4 vertical Maximiller, it should be well adapted to the heavy milling machine requirements of railway shops.

Machine for Correct Tap Grinding

GRINDING a tap consists usually of grinding the taper at the end of the tap and the clearance back of the cutting edge thus formed. This taper may be long, as in nut taps, short, as in plug taps, or almost none, as in bottoming taps. The principle remains the same in each

flute ground differently in the matter of clearance or backing off. The flute *A*, at the left, is ground with a straight line clearance just sufficient to have the h.e.l. of the flute actually clear and not drag. This calls for an angle of 15 deg., as indicated, and results in a weak cutting edge, but the strongest possible with a straight line clearance at the heel.

The flute *B*, at the top, shows a 15-deg. convex clear-

Fig. 1—Correct and Incorrect Tap Clearance

case. What is required is that each flute shall have exactly the same taper, just enough clearance so that it will cut freely, and not enough to needlessly weaken the cutting edge.

Fig. 2—A Uniform Flute Taper is Necessary

Prior to the advent of tap grinding machinery nearly all taps were ground by hand with a resultant lack of uniformity in taper and clearance. The accompanying diagram, Fig. 1, shows a section of a four-flute tap with each

Fig. 3—No. 2 Grand Rapids Tap Grinding Machine

ance. A glance shows this to be excessive. Flute *C*, at the right, shows a straight line clearance of five degrees, and nearly half of the flute at the back is not cleared at all, leaving the tap to ride on that portion and keep the front of the flute from cutting. Flute *D*, at the bottom, shows a perfect grind for ordinary work. It is a five-degree convex clearance and shows that with this small but sufficient clearance angle at the cutting edge, the back is perfectly cleared.

In addition to the correct clearance of taps a uniform angle of taper for all flutes is necessary. The results of different tapers obtained by hand grinding are indicated in

Fig. 4—General Arrangement of Spindle and Bearings

Fig. 2. Even a slight variation from the uniform taper angle means power wasted and taps broken. As the blunt angle strikes the side of a drilled hole, it throws the cutting end of the tap off center and imparts to it a wobbling motion. This means a tapped hole that is oversized, allowing the screw to fit loosely. Tap *A* is correctly ground and

will tap a hole true to size, properly located and with smooth, accurately shaped threads. Tap *B* is ground with one flute at a more blunt angle than the other. This blunt flute is shown just as it strikes the drilled hole. Tap *C* shows a similar tap after it has been crowded over. The condition developed is readily seen.

In the interest of longer life for taps and more correct work with less power consumption and fewer broken taps, the Grand Rapids Grinding Machine Company, Grand Rapids, Mich., has developed a line of machines for grinding taps. These machines are made in four styles for grinding all kinds of taps except possibly certain kinds of stay bolt taps. The No. 2, illustrated in Fig. 3, has a capacity to grind from $\frac{3}{8}$ -in. to 3-in. taps. The operator has the machine set for the proper taper and is shown grinding the tap flutes. By means of this machine the proper clearance, in the form of an arc of a circle, can be ground on any standard tap.

As with any grinding machine the spindle and spindle bearings are important, and their general arrangement on the Grand Rapids tap grinder is shown in Fig. 4. The spindles are of high carbon heat treated steel and run in dustproof phosphor bronze bearings with oil-tight adjusting collars, which prevent oil leakage. The machines are of rigid construction, being both simple to understand and easy to operate.

Nine Speed Geared Head Engine Lathe

TO meet modern requirements, a new, all-gear lathe head has been designed by the Betts Machine Company, Rochester, N. Y., and applied to the company's full line of heavy duty engine lathes, ranging from a swing of 32 in. to 48 in. The new headstock is of the all-gear, enclosed type, operated by a powerful expanding ring friction clutch upon which the driving pulley is mounted. The clutch is

reach of the operator. All speed changes are in geometrical progression and are obtained through hardened steel sliding gears and positive clutches running in oil. The edges of the gear teeth are rounded to allow for quick and easy engagement. There are 12 gears, including the face plate and pinion gear in the headstock. All back gear and triple gear speeds drive through the face plate gear, the driving pinion

Betts-Bridgford High Power Engine Lathe with All Geared Head

operated from the apron and the same movement which disengages the clutch, automatically applies the friction brake, thereby stopping the machine with no loss of time.

Nine spindle speeds including three direct, three back gear and three triple gear speeds, are obtainable quickly and are controlled by three levers located on the headstock within easy

of which can be disengaged when using direct spindle speeds. An interlocking device is provided so that no two speeds can be engaged at the same time.

All shafts and gears are located in the lower half or base of the headstock and not in the cover, which allows easy access to all of the parts, it being necessary only to remove the

cover. All the shaft bearings are bronze bushed and lubrication is obtained by a pump located in the headstock and distributing oil to all of the bearings. This reduces the possibility of any bearing running dry as long as the oil is main-

tained at the designated height. When desired the lathe can be arranged for motor drive and in this case, the motor is mounted on top of the headstock cover and directly connected through gears to the main driving shaft.

Saw With Inserted High Speed Steel Teeth

A LINE of metal cutting saws with inserted high speed steel teeth has been placed on the market by the Simonds Manufacturing Company, Fitchburg, Mass.

Among the advantages claimed for this saw may be mentioned a reduction in wear on the saw blade and the fact that when the teeth wear down they may be replaced by new ones, the diameter of the blade not being changed. Moreover, due to the inserted teeth of high speed steel, it is possible to make the body of a less expensive steel, with a resultant saving in cost.

Cold cutting saws are used in many railway shops, not only in the blacksmith shop for cutting up bar stock of all kinds, but in the machine shop for cutting out the fork ends of motion work and main rod straps. For these purposes high speed saws give a large production.

Simonds saws are now made in sizes as small as 10 in. in diameter. Up to 22 in. in diameter they can be made to cut a remarkably thin kerf, only 3/16 in. wide. Wider saws of this type are made in diameters up to 64 in.

Simonds High Speed Steel Saw

Electrically Driven and Controlled Planer

THERE is an increasing tendency in modern machine design towards electrical control and the resultant advantages in greater flexibility and ease of operation are most important. An example of electrical control in planer

is represented in New York by Alfred Herbert, Ltd. A general view of the planer is shown, and among the interesting features may be mentioned a reversing motor drive by means of a special generator set, magnetic fields and the simplicity of setting the table stroke on a graduated dial, no table dog being employed for this purpose. An additional advantage is the possibility of cross planing.

Fig. 1—Hiloplane Electrically Controlled Planer

construction is afforded by the Hiloplane, manufactured by John Stirk & Sons, Ltd., Halifax, England, which company

with the utmost ease. As previously stated, this wide range of speeds, taken with the sturdy construction of the planer,

It is possible to obtain high speeds with the electrically controlled planer, and on the other hand low speeds are available for special work. Particular attention is called to the magnetic feeds. A special motor generator set is used to supply current to the d. c. driving motor, and the latter is controlled by varying the field resistances of the former. The fields are excited independently and any variation in resistance changes the voltage with a corresponding change in armature speed. It is thus possible to obtain an infinite variety of speeds from a given normal speed down to zero. In practice the actual motor speed is seldom reduced more than 25 per cent on account of reduced torque. By adjusting the resistances in the fields, the upper limit of the reversing motor speed is usually increased, and any one of a large range of speeds can be obtained

makes the machine capable of maintaining the maximum speeds possible for ordinary duty on mild steel and also for extra heavy cutting at low and medium speeds on hard metal. Variations are made by the finest steps, and cutting speeds and return speeds are independently variable. A patent accelerating device is provided, by which the cutting speed may

Fig. 2—Box Section Bed With Continuous Top Plate

be increased after the tool has entered the metal, or between surfaces. In this way gaps between surfaces may be quickly bridged which is an important advantage and time saver both in cases where the gap is between different pieces set up on the planer bed, and between two surfaces on the same piece.

A wide range of feeds is obtained by the magnetic feed control fitted to both the cross slide and vertical heads. By means of this arrangement variable and reversing self-acting

Fig. 3—Table Control Mechanism

feeds are obtained in horizontal, vertical and angular directions. Special provision is made for broad finishing cuts. The feed obtained depends upon the position of the handle in the horizontal slot shown in Fig. 4. A small separate feed motor shown in Fig. 4, is used for quick power traverse of the heads, which is obtainable in all directions. This also

makes it possible to perform cross planing jobs, a valuable feature for short bosses on large pieces because it avoids an additional set up of the work.

The table control mechanism, illustrated in Fig. 3, is simple and the length of the table stroke is obtained by fitting stops on the graduated dial, instead of setting table dogs. The reversal of stroke is obtained by the action of the stop on a reversing switch. By means of this electrical control and the absence of table dogs, it is possible to obtain a stroke of 4 in. The table may be started or stopped from either side of the

Fig. 4—View Showing the Magnetic Feed Control

bed, and a hanging switch is provided for convenience in setting up. A safety switch arrangement also prevents the table from running off the tracks.

To insure safety at high speeds, the pinions are forged solid with their shafts. The motor generator set is not mounted on the machine but in a convenient position apart, thereby eliminating vibration. The control of the table is by a switch button for starting and stopping. Due to its flexibility and ease of control, this machine is adaptable to a wide variety of planing operations in machine shops where high production and accurate work are the ends in view.

Side Cutting Pliers With Renewable Jaws

PROBABLY the weakest point in the pliers ordinarily used by electricians and mechanics has been the jaws, and to overcome this weakness the Neverslip Works, New Brunswick, N. J., has developed a type of pliers with renewable steel jaws. This important feature makes it unnecessary to throw away a pair of pliers in case the jaws become broken or worn out. It is only necessary to remove the worn blades and insert new ones, which is a quick, inexpensive operation.

Another feature of the side cutting pliers, illustrated, is the fact that the method of making them in two parts permits the manufacturer to select the best possible steel for each

purpose. The jaw blades are made of high grade crucible steel, insuring both tough and sharp jaws. The handles

Pliers With Renewable Jaws

are made of drop-forged steel, which reduces the chances of breaking under ordinary usage to a minimum.

Production Automatic Milling Machine

AN AUTOMATIC milling machine intended for the manufacture of duplicate parts in large quantities has been placed on the market recently by the Brown & Sharpe Manufacturing Company, Providence, R. I. It is essentially a manufacturing machine, known as the No. 21 automatic milling machine, Fig. 1. It has structural characteristics common to the other styles of plain milling machine of the column and knee type, but in the application of automatic control to that of a plain milling machine, many new and important features were developed.

By means of adjustable dogs on the front of the table, the control of the spindle and table is entirely automatic. These movements include a variable feed, constant fast travel and a stop for the table; start and stop, and right and left hand rotation for the spindle. The table and spindle may be operated independently of each other, and these movements may or may not be intermittent in either or both directions and may take place one or more times. The spindle may be

the direction of the table travel is to the right, and as shown at *D2* when the direction of the table travel is to the left.

The table always moves at its constant fast travel when reversed, and when the machine is set for reversing the spindle, the spindle is reversed when the table is reversed. When the machine is set for stopping the spindle, the spindle stops when the table is reversed and starts with the fine variable table feed. No extra tripping dogs are required for either reversing or stopping.

Continuous milling operations may be performed by em-

Fig. 1—Brown & Sharpe No. 21 Automatic Milling Machine

Fig. 2—Automatic Spindle and Table Control Is Secured by Adjustable Dogs

ploying two *A* dogs and two *D* dogs, and for intermittent milling operations, dogs *A* and *B* and dogs *C* and *D* are employed, the number of pairs of *C* and *D* dogs depending upon the number of pieces of work on the table.

Although the automatic control of the spindle and table is by means of table dogs, the same results may be attained by hand, employing the two controlling levers located on the front of the saddle. Occasionally the loading time of a piece exceeds the cutting time, and the table is set to stop for the

stopped upon the return travel of the table, thus eliminating the possibilities of marring the work, and the spindle reverse allows the use of two sets of cutters, with teeth facing in opposite directions, so that one set may be in operation for one direction of table travel and the other set for the opposite direction of table travel. A constant fast travel and a slow, variable feed in both directions are automatically controlled by the table dogs.

There are four different style dogs necessary to operate all the automatic movements of the machine, but for all ordinary milling operations, two or three of the styles are usually sufficient. A long dog *A*, Fig. 2, used at *A* or *B* controls the reversing of the table. This same dog also stops the table, if it is so desired, and the table stop lever is set. Dog *C* controls the constant fast travel, and dogs *D1* and *D2* control the variable slow feed, it being possible to set these dogs to operate in either direction. The variable slow feed dogs are trip dogs made changeable to operate, as shown at *D1*, when

Fig. 3—Spindle Speed Change Gear Case

safety of the operator. Under these circumstances the machine is semi-automatic in operation, and the hand control levers are employed in place of the dogs.

Manipulation of the controlling levers is extremely simple, and the ease and rapidity with which they may be operated is in some cases faster than when it is fully automatically operated. By means of the hand-control levers, the machine may be operated as a plain milling machine.

The constant speed type of drive permits the machine to be driven by a belt directly from the main shaft to the single-

driving pulley. Mounted upon the drive shaft are the friction clutches for starting, stopping and reversing the spindle automatically, and this arrangement relieves the spindle of all unnecessary weight. Power is transmitted from the shaft to the spindle through a series of spiral bevel gears, which furnishes a smooth and powerful drive.

Another advantage of the constant speed type of drive is the complete separation of the spindle speeds and the table feeds, permitting any combination of the two within the

Fig. 4—View Showing Adaptability for a Vertical Milling Attachment

capacity of the machine. Variations of the spindle speeds are obtained through change gears, giving 16 changes of speeds in geometrical progression from 28 to 695 r.p.m. in either direction. The table feeds are positive and are entirely independent of the spindle speeds. There are 12 changes, ranging from 1.37 in. to 18.38 in. per minute. This provides a range of 0.002 in. to 0.050 in. per revolution of the spindle for small mills and 0.026 in. to 0.656 in. per revolution of the spindle for large mills. Both sets of change gears are contained within heavy cast iron cases and are made readily accessible by doors, upon which are cast tables of the

proper gears for the various spindle speeds and table feeds. The spindle speed change gear case is shown in Fig. 3.

When motor drive is desired, the motor is placed at the rear of the machine where it is completely out of the way and does not increase the floor space occupied. In this case the motor is mounted on a heavy bracket firmly bolted to pads provided on the base of the machine. A belt transmits the power from the motor to the single driving pulley and a cast iron guard protects these parts from dust and grit and the operator from injury.

The front end of the spindle is tapered, hardened and ground and has a recess to receive a cutter driver and clutch on arbors and collets. The reverse gearing and cams, actuated by the table dogs are assembled as a unit in an oil tight case and this unit of mechanism is automatically lubricated and protected by a safety friction coupling set to slip at a predetermined load, thus guarding against possible damage. The other unit of mechanism that responds to the action of the table dogs is that which controls the constant fast travel of the table and the variable table feeds. This unit is provided throughout with ball bearings and is also automatically lubricated, being contained within an oil tight case. The adaptability of the machine for use with a vertical milling attachment is illustrated in Fig. 4.

The automatic lubrication of all rotating parts within the frame of the machine is another important feature. Filtered oil is pumped to a reservoir cast in the top of the frame and by means of pipes and a gravity system oil is constantly distributed to the various bearings. For manufacturing purposes an abundant supply of cutter lubricant is pumped from a large tank located within the base of the machine.

Realizing the importance of a rigid construction in a high productive machine of this type, the designers have embraced features adapted to these conditions. The column, knee, and table, are provided with internal bracing and reinforcing ribs. The wearing surfaces of the table and bearings throughout the machine are of such proportions as to provide for the severe service to which a strictly manufacturing machine is subjected.

The machine has a longitudinal table feed of 22 in. and transverse adjustment of $6\frac{1}{2}$ in. with a vertical adjustment of $14\frac{1}{2}$ in. The spindle is provided with a No. 10 taper hole. The speed of the drive shaft is 300 r.p.m. and the power consumption is 5 hp.

Compression Coupling Saves Time and Labor.

A MATERIAL saving in the time and labor heretofore required for connecting line shafting can be effected by the use of a new compression coupling manufactured by the Cincinnati Ball Crank Company, Cincinnati, Ohio. The outstanding features of the coupling are simplicity, ease of application and adaptability to all standard shafting.

In construction, the coupling shows a radical departure from the old type of flange and bolt connection. It consists of only five pieces; three jaws, and two clamping rings. The jaws of the coupling are set in position about the shaft, and held in place by the longitudinal grooves and notches that lock them together. The forged clamping rings are pushed on over the tapering ends of the jaws, and hammered tight.

A hammer is the only tool required to apply the coupling, no dismantling or machining of the shaft sections being needed. The only requirement is sufficient clearance between the sections to allow the clamping rings to pass.

The coupling grips the joined sections of the shaft, holding them in alignment. The round, machined sections of the tapered end of the coupling jaws form lines of contact

for each ring, and once driven into place, it is practically impossible for the coupling to become loose. Compression

Cincinnati Compression Coupling

couplings of this type have been in use three years with no adjustment since their installation.

The assembled coupling forms a clean, compact shaft joint with no projections on its outer surface to catch a workman's clothing, thus insuring safety for employes. When used as a reducing coupling, the only additional parts needed

are three strips of cold rolled steel to fit between the smaller shaft and the inside of the coupling jaws. The couplings are made in sizes to couple shafting from 15/16 in. to 3 in. in diameter.

High Power Selective Head Engine Lathe

A WELL balanced line of engine lathes, designed for quantity production as well as general machine shop work, has been placed on the market recently by Joseph T. Ryerson & Son, Chicago. The machines are made in five different sizes, including 15-in., 18-in., 22-in., 27-in.

For convenience in operation and cutting down all possible lost motion, the lathe controls have been centralized on the apron, and from one position the operator may start, stop and reverse the spindle instantly, engage, reverse or trip the feed, as well as traverse the carriage and cross slide. The 12 spindle speeds are changed by means of two levers on the headstock, one of which controls the various sets of change gears and the other the back gears. The action of both levers is practically instantaneous, and all changes may be made while the lathe is in operation. The handwheel, shown on the headstock, can be turned to any desired feed marked on its circumference, automatically selecting the feed indicated.

To secure greater rigidity, the lathe headstock has been cast integral with the bed, the latter serving as a container for oil, in which part of the gears run. All gears are lubricated by the splash oil system. The spindle is proportionately large in diameter to eliminate vibration as far as possible, and a ball thrust bearing takes up the heavy working strains. Power is transmitted to the spindle through a phosphor-bronze driving pinion and a large herringbone gear. This type of drive reduces back lash to a minimum and gives a steady driving torque. The back gears, as well as all change gears, are permanently in mesh, and all changes can be performed with rapidity and without danger of engaging more than one set of gears at a time.

The spindle drives a large spur gear connected to the feed-reversing mechanism, which is operated from the apron. Twenty-eight feeds are obtained by two sets of geared cones, which in turn are actuated by a handwheel and lever on the headstock. The carriage longitudinal and cross feeds are effected by independent sets of worm gears which are engaged by large friction cones. The positive feeds consist of a large split nut made of phosphor-bronze and an effective safety device is provided. One lever on the apron controls the start-

Single Pulley Drive Arrangement

and 33-in. swing, with any length of bed. A notable feature in the design is the method of driving. With very slight changes the lathe can be adapted to constant speed single pulley drive, with or without spindle reversing attachment, or direct revers-

Motor Driven Engine Lathe Designed for High Production

ing motor drive. In the latter arrangement the motor is bolted to the bed and the armature shaft connected directly to the main driving shaft, doing away with belts, tension idlers and chain drives. The changing from belt to motor drive or vice versa can be made at any time and at a small cost.

ing, stopping and reversing of the spindle, and one lever controls the engaging, tripping and reversing of the feeds. Arrangement is made to automatically trip either the friction or the positive feeds at any point along the carriage travel.

Particular attention has been paid to the cross sections and

proportions of the ways of the bed. The guiding surface of the vees is inclined at 15 deg. to the perpendicular and the supporting surface at 15 deg. to the horizontal. The vertical depth is at least twice as great as in the usual construction

and, due to the broad supporting surfaces, the wear on the carriage and ways is reduced to a minimum. The usual extra attachments can be supplied with the new Ryerson-Conradson lathe, if required.

Boring Mill for Heavy Accurate Work

ONE of the most desirable characteristics of a machine tool designed for railway shop work is the ability to stand up under heavy roughing cuts in tough steels, and possibly in the very next operation produce some machine part to a fine limit of tolerance. It would be difficult to devise a more strenuous test of a machine tool's ability to render consistent service on all classes of work within its range and yet, the above test is one which must be met every day in railway machine shop work owing to the widely divergent character of the machine operations to be performed.

Fig. 1—Bullard 44-in. Maxi-Mill

Equal facility in taking cuts up to its maximum capacity or doing work requiring a high degree of accuracy is possessed by the 44-in. Maxi-Mill illustrated in Fig. 1. This new machine, made by the Bullard Machine Tool Company,

Fig. 2—Improved Secondary Speed Change Case

Bridgeport, Conn., is the smallest one of a line of boring mills embodying the principles of unit construction, centralized control, continuous flow lubrication, and cutting

lubricant system previously described in the June, 1918, *Railway Mechanical Engineer*.

Certain improvements have been made in the secondary speed change case, shown in Fig. 2, to secure a power unit of maximum strength and durability.

The most important improvement in the new design is the

Fig 3—Bullard Independent Face Plate Jaw

use of two driving gears, rigidly keyed to the drive shaft instead of sliding upon it. The clutch gears have internal teeth meshing with spur gears and form a positive lock. The gears are all of relatively greater size and so guided upon their mating gears as not to produce braking shocks when shifted.

A plain table with radial T-slots, three-jaw combination

Fig. 4—General Dimensions of Independent Face Plate Jaw

chuck, or four-jaw independent chuck, may be provided with the 44-in. Maxi-Mill. Both the three and four-jaw chucks are powerful and have been developed to meet the exacting requirements of the vertical turret lathe. The chuck bodies are heavily proportioned to avoid distortion and operating parts are made of selected materials best suited to the service required. The sliding jaws are of forged steel accurately fitted to the chuck body and special arrangement is made to prevent foreign matter getting into the operating mechanism, which is packed with non-fluid oil and graphite. The top jaws are adjustable, mounted on sliding members and may be reversed or removed readily.

In case odd shaped pieces are to be machined, or work that is off center, the best arrangement is to use independent face plate jaws in conjunction with a plain table. These jaws, one of which is illustrated in Figs. 3 and 4, are both convenient to operate and great time savers. They are not limited to machines having the Bullard standard arrangement of T-slots.

The bodies of the independent face plate jaws are made

of drop-forged steel. The top jaw, Fig. 3, is made of special steel, and is not liable to distortion or fracture under severe service. The actuating screw being placed at an angle with the jaw gives a powerful differential movement, which resists any backward strain or tendency to loosen the jaw when under cut. This arrangement also permits the operator to use a wrench on either end. The jaws are securely held to the slots of the table by two bolts and are reversible.

Small Portable Pneumatic Tools

SEVERAL new sizes of small portable tools have been added recently to the line of "Little David" pneumatic tools manufactured by the Ingersoll-Rand Company, New York. The new tools, as shown in the illustrations, include a No. 8 small close quarter drill, two small high speed pneumatic grinders, No. 601 and No. 602, and two lightweight drills, No. 6 and No. 600. It is poor economy to

and has several unique features. The spindle which turns the drill, reamer or tap, is operated by three rocking levers connected directly to the pistons through connecting rods. The motor is of the three cylinder type with pistons acting at right angles to the levers. A steady, continuous movement of the spindle is obtained, as one ratchet pawl is always in contact with a tooth of the spindle. The construction is simple and sturdy, with the least number of parts consistent with approved design.

The No. 601 and No. 602 grinders run with a free speed of 4200 r.p.m. and are suitable for grinding, buffing or polishing work of a varied nature. Each machine has the same type of motor, but is equipped with a different throttle and handle. The No. 601 has the closed type of inside trigger handle, while the No. 602 is fitted with the rolling type of throttle handle. A special feature of these tools is the three cylinder motor (entirely different from that of the

Ingersoll-Rand Close Quarter Drill

use heavy pneumatic tools for light work and the lightweight, high speed machines described in this article are well adapted to railway shop work often done with heavier equipment.

The close quarter drill is for use in a limited space close

High Speed Pneumatic Grinders

to a wall or corner. This new machine has a fairly high speed, running at 250 r.p.m. without load, but will handle drilling, reaming or tapping up to 1 1/4 in. diameter. The tool is specially designed throughout for close quarter work

Light Weight Pneumatic Drills

No. 8 drill, described above) which runs constantly in a bath of oil, insuring lubrication of all the parts. Lack of proper oiling has been one of the reasons for grinder troubles in the past. The valve is made integral with the crankshaft, simplifying the design, and the piston and connecting rods also are of special construction. Ball and roller bearings are used throughout. The removal of a few screws enables the handle to be lifted off and exposes the entire mechanism to view, making inspection of the parts easy.

The No. 6 and No. 600 drills meet the demand for light air tools required to drill small holes without breaking the drills. They will handle twist drills from the smallest size up to 3/8 in. diameter. The free speed at 90 lb. air pressure is about 2000 r.p.m. The two machines differ essentially in the handle construction, the motors being the same. The No. 6 has the pistol grip type of handle, while No. 600 is furnished with breast plate and rolling throttle handle. Aluminum, reinforced with steel bushings, is used wherever pos-

sible and results in a lightweight machine; the No. 6 weighing only 9 lb. The motor is a three cylinder type somewhat similar to that used in the grinders mentioned above. The cylinders are separate iron castings, easily accessible,

renewable and interchangeable. A sensitive throttle control has been obtained, which with freedom from vibration makes the tool well adapted for drilling with small drills. The bearings are all either of the ball or roller type.

Vortex Paint Spraying Equipment

PAINTING with mechanical appliances for industrial buildings, tanks, and other large equipment has been a recognized method long enough to win a firm contingent of supporters and also to array an equally firm support behind the older process of hand painting. That the hand painter holds on can only be regarded as proof

Vortex Painter in Use On Metal Building

that the problem of mechanical painting is more difficult than imagined by many of those who have offered various shapes and forms of spraying devices.

A few of the characteristic difficulties of paint spraying are (1) loss of paint, (2) scattering and splashing over surfaces not to be painted, (3) difficulty in the open air owing to wind interference, (4) pre-drying of the paint

to a chalky consistency through evaporation of its volatile oils while in the air.

With these difficulties in mind, a paint spraying equipment has been perfected by the Vortex Manufacturing Company, Cleveland, Ohio, and placed on the market. The equipment includes a portable air compressor, paint tank and a nozzle. The Vortex nozzle has two openings, a central opening for paint and an annular opening around the center from which the air is discharged under a pressure approximating 60 lb. per sq. in. There are separate conduits for air and paint, terminating in a right angle on each side, which forms an axis for the nozzle and permits it to be operated at any desired angle.

The paint is driven from the central outlet under low velocity and is immediately picked up by the surrounding air jet and carried to the painted surface. The air jet is too powerful for the paint to penetrate and the loss from spattering is remarkably small, the whole tendency being to spread evenly rather than spatter.

It is claimed that the Vortex painter carries a greater volume of paint per minute, due to the fact that it is not finely sprayed but applied in a relatively heavy liquid jet; there is a better penetration of rough surfaces and a more efficient brushing action by the air jet which makes it possible to cover completely and smoothly with a single coat. Scaffolding can be very largely dispensed with by use of a 12-ft. arm, when desired. There is also the important advantage of having a powerful air jet for cleaning dirty surfaces and reaching crevices and out of the way corners.

Any fairly efficient jet system should have an advantage over brushing in the treatment of rough surfaces, such as rock faced masonry, rough lumber, etc., because perpendicular application of the paint is certain to penetrate voids better than brushing across the surface.

It is possible to paint 2,000 sq. ft. per hour or more on plain interior work with a Vortex painter where conditions are favorable and the operator experienced in his task. A striking demonstration of possibilities in outdoor work was the painting of a large storage tank on the roof of a building. This was given a single but sufficient protective coating of red in three and a half hours, although the tank had 3,500 sq. ft. of surface. It rose 18 ft. from the top of the tower on which it was located and no ladders or scaffolding were required.

Air Required to Operate Preheaters

THE following data are the result of recent tests made by the Metal & Thermit Corporation, New York, to determine the proper amount of air required for special thermit welding gasoline and compressed air preheaters. The practical minimum pressure for operating preheaters appears to be 25 lb. per sq. in. At this pressure a single burner preheater will require approximately 25 cu. ft. of free air per minute and a double burner preheater approximately 50 cu. ft. of free air per minute. For very large welds, where the walls of the molds are thick and the preheater gates longer

than usual, a pressure of 40 lb. per sq. in. would be advisable, which would require approximately 35 cu. ft. of free air per minute for a single burner preheater and 70 cu. ft. of free air per minute for a double burner preheater.

In the case of large shops with a central air compressor plant, upon which demands are being made by many departments, the pressure quoted above should be maintained at the outlet to which the preheaters are attached. This is a very important point as, too often, the operator forgets that a considerable loss of pressure takes place in the pipe line.

Large Capacity Multiple Spindle Automatic

A MARKED advance in automatic screw machine design has been registered in the development of large capacity 3-in. and 4-in. multiple spindle automatic screw machines by the National-Acme Company, Cleveland, Ohio. These machines were evolved as a result of the demand for a larger unit of the National-Acme line, which previously only had a range up to $2\frac{1}{4}$ in. Two of these machines have been installed in a railroad shop and are very successfully working on side rod oil cups, ball joint rings for injector branch pipes, etc.

Many new features were incorporated, necessitated by the large capacity of the machines and to insure rigidity and accuracy under heavy cuts and feeds. Heavy and rigid design to cope with tough composition steels, maximum cutting feeds and speeds made possible by modern tool steel, precision and fast output were the goals. These combined with standardization of equipment, convenience in operation, safety devices, reduction in unit driving power and simplicity of design have been secured in this machine, still ad-

at a 45 degree angle with respect to the lead cam, and its movement is against a hardened steel plate screwed to the bed. The bearings receive no side thrust from the lead and take-back cams.

Because of this rigid system of supporting the tool carrier, side thrust is equalized so that heavy cuts and coarse feeds may be employed to the maximum capacity of the machine, and yet insure accuracy.

The stop-rod between the pusher and the carrier is the main stop for accurately regulating the length of the turret travel. This is controlled by nuts adjusted for different lead cams. Tool holders having wide bearings are fastened against four flat surfaces of the turret, and are supported directly underneath their cutting points with no overhang.

The forming and cut-off slide bearings are cast with the bed, and so designed as to support the forming tool its entire length, and directly underneath the cutting pressure. The connection between the forming and cut-off levers and their slides is through a $2\frac{1}{2}$ -in. hexagon shaft, assuring

Acme Multiple Spindle Automatic, 3-In. to 4-In. Capacity

hering to the principle of performing all screw machine operations in the time of the longest single cut. One notable departure has been made in the method of tooling, however, so that the 3-in. and 4-in. machines use right hand tools exclusively.

The design of the main tool slide or end tool turret provides the most rigid support for tools, as well as accessibility for setting up. It is a semi-steel casting in one piece, one end of which extends ahead of the four-faced turret proper and has its bearing in the center of the cylinder. The rear end is supported in a heavy bearing through an upright extension of the frame, which is cast integral with the bed itself. It is supported just back of the tools by an extension of the pusher rod which controls the feed of the tool carrier. This pusher is independent of the tool carrier proper, being connected to the carrier at the top by a pin, and at the bottom it travels on a wide-bearing plate mounted on the center of the frame. From the pusher rod is an extension with a roller for the lead cam. This extension is fastened to the pusher rod which is supported

positive feed to the slides, without spring. The slides are adjusted vertically by taper gibs, and horizontally by straight gibs. The levers, controlling the feed of the cross slides, are provided with slots, making them easily adjustable and requiring only minimum change of cams for different feeds. With this adjustable arrangement, for forming and cut-off levers only three cams are required for all work within the capacity of the machines, two being ample for normal work and furnished with the machine.

A forming stop, consisting of a bracket mounted on the slide in connection with adjustable studs located between each of the four spindles, provides a separate adjustment for each, and is a further safeguard for uniformity of product.

To facilitate quick, accurate adjustment for the depth of cut for the forming and cut-off tools, screws are operated through the center of the slides independent of the tool holders.

The top slides are operated by two straight and interchangeable cams through rods and levers, arranged so that

both slides can be adjusted by manipulating one interchangeable cam on the main cam shaft. The lever shaft controlling the travel of both slides is hexagonal, thus obviating any chance of the loosening, common to key set shafts. The top slides accommodate the same holders and tools that are used on the forming and cut-off slides, and the method of adjusting the slides by gibbs is the same.

New features in the cylinder construction tend to minimize wear and provide easy adjustment. The cylinder casing has been made unusually strong, and in addition to being secured to the bed by heavy bolts, the casing is dovetailed to the bed. Two brass shoes are located independently on top of the cylinder casing for both front and rear bushings, and are adjusted by screws without any interference with the top slide. It should be borne in mind that this adjustment is made toward the center of the machine, the point of greatest strain.

Compensation for end wear is provided in a take-up located on the rear of the cylinder, secured by adjustable brass shoes on the reel cross support, and tightened to the cylinder. The cylinder does not depend upon its bearing against the adjustable shoe resisting the end thrust, because the front of the cylinder casing is counter-bored, thus giving the cylinder a bearing on its entire periphery.

The front and rear spindle bearings are of the straight type, the material being a special bronze composition with end thrust bearings. Most important is the point that the spindles proper are not affected by wear, because a main bronze bearing is secured to the spindles and runs in a hardened steel bearing fitted to the cylinder. Moreover, the spindle gears are located centrally between the bearings instead of at the ends of the spindles; thus the pressure of the gears tends to equalize the action against the bearings on the spindle, at the same time affording rigid support by reason of the bearings being located further apart. The result of this new construction is easy rotative action, less power, higher cutting speed and easy replacement of both spindle and cylinder bearings when worn.

The drawback type of collet is used, the advantages of this collet as compared with the push type being five-fold: (1) they run true because they are drawn back in a taper which has been ground in the spindle itself; (2) the stock

are protected when forming, because drawback chucks permit of a much shorter projection of the spindles from the cylinder.

While this machine is not fitted with the threading spindle, unless so ordered, provision is made for including it as a

Forming and Cut Off Slide Showing Adjustable Lever

part of the standard equipment. The die spindle runs right-handed. It is operated independent of the travel of the main tool carrier and has two cutting speeds, either 1 : 3 or 1 : 5 in ratio to the revolutions of the work spindles, also two speeds for running off the work. A double gear

Tool Set-up and Operations in Forming a Gear Blank

feeds more easily; (3) the collets hold more tightly under heavy end thrust, such as drilling or heavy turning; (4) there is no strain or spring at the stock stop, because in locking the stock, the bars draw back away from the stop instead of pushing against it; (5) the spindle bearings

is used—one mesh for one speed and another for a different travel. Spindle speeds are varied by shifting the double gears. Change from left-hand to right-hand threads is accomplished merely by reversing the cams operating the friction. When button dies or taps are the threading equip-

ment, an extra holder is used; but for opening dies or collapsing taps, only the regular equipment is required.

The turnover of the stock-carrying cylinder is accomplished by the Geneva movement and is quick, positive and with minimum strain or wear. Locking of the cylinder in the four successive positions is secured by a lock bolt on the forming side of the cylinder and a latch bolt on the cut-off side. This arrangement has been found most practical, because the lock bolt naturally pulls the cylinder down, and with this system there is less competing pressure.

Positive operation of the lock bolt is controlled by a spring directly in connection with the bolt and by a cam and roller from the main cam shaft, thus securing a rigid locking when heavy or exceptionally long bars are used.

Stock may be fed in either the first or fourth spindle positions according to the class of work in hand. The slide controlling the stock feed is independent, having its bearing on two rods between the casing and the end of the machine. It is equipped with double levers connected by rollers, and one of these rollers is changed in two positions for the 6-in. and 12-in. feeds. Intermediate feeds are secured simply by adjusting the collar on the stock pusher rod.

The pan is of unusual size constructed with three strong ribs in the floor portion and the bed which is screwed to the pan is in one piece, except the cylinder casting, which is screwed and dovetailed on as explained above. All the main gears are steel, the levers are steel castings and the main tool carrier is semi-steel.

Ample clearance is provided for chip room by the open construction below the main tool turret. The oval form of the center bed allows the chips to be washed off quickly into the pan. The general operating mechanism, forming and cut-off are under the cylinder, thus separating the chips from the working parts.

All the tools on the main tool carrier are inside the circumference of the spindles, thereby allowing for tool con-

struction of varied sizes and shapes without interfering with each other or with the center turret extension.

The bearings for the back gears, also for the worm drive, are connected with a single oil reservoir mounted over the gear box. The feed of oil is regulated individually by thumb screws at the bottom of the reservoir, and all the oil tubes have a main shut-off so that individual adjustments do not need to be disturbed when the machine is stopped. The main spindle bearings are provided with oil chambers supplied by gravity feed cups.

Safety and convenience of operation have been carefully considered and cared for in the design of this machine. All working parts, such as gears, cam drums and friction, are completely housed. A safety device is applied direct to the worm gear on the cam shaft as follows: Instead of keying the worm to the cam shaft, a disc is keyed on the shaft parallel to the worm gear and joined with shearing pins which are easily replaced when broken. This device prevents accident, due to irregular stock feeding, mis-alignment of feed tubes and errors in setting up the tools.

In addition to the provision made for cranking by hand from the forming side of the machine, an extension, from the worm shaft to an independent stud and through to the cut-off side of the machine, allows the operator to crank the machine from either side, thus conveniently observing the movement of the tools while setting up.

The starting clutch lever for throwing into automatic feed is also controlled from either side; and when thrown into automatic feed, the hand crank is automatically disengaged, thus avoiding any possibility of accident due to negligence.

The machines are furnished either belt or motor driven. When motor driven a 10-h.p. motor is required for the 3-inch machine and a 15-h.p. motor for the 4-inch machine. Top slides, threading attachment and an accelerated reaming and high speed drilling attachment are not standard equipment furnished with the machine.

Exceptionally Large Plate Bending Rolls

ONE of the largest plate-bending rolls built in the central states has just been purchased by the General American Tank Car Corporation of Joseph T. Ryerson & Son, Chicago. The machine is of exceptional size, and is provided

bearings directly on cast iron. This machine measures 34 ft. 2 in. between housings and has a capacity for bending $\frac{3}{4}$ -in. mild steel plates. The top roll is 29 in. in diameter and weighs about 40 tons. The bottom rolls are 21 in. in

Plate Bending Rolls that measure 34-ft. 2-in. between Housings and can bend $\frac{3}{4}$ -in. Mild Steel Plates.

throughout with steel gears and bronzed bushed bearings. In the past it has been the custom to build heavy machinery of this kind with cast gears and either babbitted bearings or

diameter and have two roller supports. The rolls are mounted on a rigid cast iron sub-base and have independent motors for main drive and power adjustment of the top roll.

Pilot Brush Increases Gage Life

IN order to provide a wider field for the use of plug and screw gages and to increase the life of many gages now used in manufacturing processes, a combination brush and gage has been developed and placed on the market by the Brush Pilot Gauge Company, Springfield, Mass. By the use of this combination brush and gage, more accurate testing is accomplished and the life of the gage is greatly increased because of the removal of dirt and foreign matter. The brush also acts as a pilot, thereby eliminating almost entirely the wear commonly occurring at the entrance end of the gage. More accurate testing is another advantage resulting from the elimination of end wear on the gage.

Cleaning the surface before the gage enters a test piece prevents abrasive action, and at the same time gives increased accuracy to measurements and increased speed to the inspection work. The spiral brushes are so made as to leave the bristles at slightly varying lengths and when used in conjunction with a screw gage, the bristles tend to thoroughly clean out the thread both at the top and the bottom. The illustration shows a brush applied to two common types of test gages.

It is claimed that the pilot brush will increase the life of

a test gage approximately three hundred per cent, resulting in an important saving to any manufacturing machine shop where the simplest kind of plug gage costs five dollars.

Pilot Brush Applied to Familiar Types of Test Gages

Powerful All-Geared Head Engine Lathe

A NEW, all-geared head engine lathe with a swing of 60 in. and 72 in. has been designed by the Betts Machine Company, Rochester, N. Y. The headstock is driven through a powerful expanding ring friction clutch which is operated from the apron, convenient to the operator. The same movement which disengages the clutch automatically applies the friction brake. There are 12 spindle speeds

engagement and no two speeds can be engaged at the same time. Shafts and gears are located in the lower half or base of the headstock and not in the cover, thereby allowing easy access to all of the parts, it being necessary only to remove the cover. All shaft bearings are bronze bushed and all bearings are lubricated by means of chain oilers. When the machine is motor driven, the motor is mounted on top of the

Betts-Bridgeford All Geared Head Engine Lathe; 60-in. and 72-in. Swing

in geometric progression, controlled by conveniently located levers at the front of the headstock. All speeds are driven through an internal face plate gear and pinion.

All speed changes are obtained through hardened steel sliding gears and positive clutches running in oil. The edges of the gear teeth are rounded to allow for instant and easy

engagement and directly connected through gearing to the main driving shaft.

There are 32 changes of feed and lead obtainable through quadrant gearing and a quick change gear box to the lead screw. Feeds are driven from a spline in the lead screw to the rack on the bed through large all-steel gears. No two

feeds can be engaged at the same time and feeds and leads are interlocking so that only one can be in use at one time.

All shafts in the apron have a bearing on each side, the apron being of double wall unit casting construction. The power angular feed to the compound rest is driven from the cross feed friction, a slip gear being provided for cross feeding or power angular feed. Both feeds and leads may also be reversed at the headstock. Power rapid traverse is obtained by

means of a friction clutch on the lower shaft in the quick change box, which is driven from the constant speed headstock driving shaft by means of a Morse silent chain at the head end of the lathe. The rapid traverse is operated by a lever at the apron. The movement which engages the rapid traverse clutch automatically first disengages the feed and lead, making it impossible to have both engaged at the same time. Power angular feed is provided on the lathe.

Staybolt Cutter and Yoke Type Riveter

TWO pneumatic tools of particular interest are being introduced into railway shops by the Baird Pneumatic Tool Company, Kansas City, Mo. The staybolt cutter, illustrated, can be operated by one man and is used in clipping off staybolts up to $1\frac{1}{8}$ in. in diameter at the rate of approximately 1,200 per hour. The machine is composed of a 15-in. air cylinder, the piston of which connects directly through a toggle joint with a pair of lever arms, into which the removable cutter knives are securely fastened. These knives are of sufficient strength to withstand the heavy pressure required in clipping staybolts. The working pressure is 100 lb.

A pressure of eighty tons is delivered to the cutter knives, which is sufficient to clip off staybolts up to $1\frac{1}{8}$ in. in diameter. The cutter blades are so designed that, when placed against the sheet, the staybolt is cut off just the right distance from the sheet, to allow for heading over. This feature is

Baird Pneumatic Staybolt Cutter

a great time and labor saver and insures uniformity of work.

An additional advantage is the elimination of loose bolts caused by cutting them off with a hammer and chisel. The machine can be operated on modern radial stay boilers and is balanced to be held at any desired angle.

The length of the staybolt does not affect the operation of the machine. When long bolts are to be cut off a special pair

of blades is used and the machine operates on an angle so that the bolts do not interfere. The machine is designed to be operated by one man and on account of its light construction and the convenient position of control valves, can be easily operated.

For the construction of truck frames, tank frames and locomotive boilers the yoke type riveter, illustrated, can be

Pneumatic Yoke Type Riveter

used to good advantage. The machine is equipped with a tandem cylinder having two pistons on a single rod. The necessary guide cylinder is utilized as a power cylinder and this arrangement doubles the power of a single cylinder. The stroke is short and the power is delivered with a quick direct blow. The construction obviates the necessity for large diameter cylinders of long stroke, or the double toggle or other arrangement.

The connecting rod of the riveter varies only one-half inch from a direct line from start to finish of the stroke. At the finish, when maximum power is desired, it is on a direct line. The toggle principle has the advantage of being small, compact and simple, with few bearings and little lost motion. The lever is an integral part of the lower toggle lever and develops its greatest power at the finish of the stroke. The adjusting screw is of the buttressed screw type, which has the advantage of a direct flat bearing surface, which reduces wear and lost motion to a minimum.

Because of the practical elimination of lost motion, rivets are driven rapidly with one blow before their heat is dissipated. A uniform set of each rivet therefore is obtained. Various sized cylinders can be furnished to deliver any desired tonnage to the dies. The control of tonnage delivered to the rivets can be regulated by an air line pressure valve to suit any class of work. This saves wear and tear on the machine and is economical in the use of air. Steam as well as compressed air can be used, although air is preferable. Suspension of the yoke type riveter is by a bale or link

through the center of gravity, permitting operation from a horizontal or vertical position, or at any angle between. On larger sizes, foot brackets or rests are provided for installing the riveter in a stationary position by embedding in concrete. The operating handles for control valves on the standard equipment are placed on top of the cylinder.

Particular care has been given to eliminating exposed parts which might catch the clothing or person of the workman. The operation of the lever and toggle joint is such as to practically eliminate danger of personal injury.

Two New High Speed Milling Cutters

BOTH solid and inserted blade milling cutters are now in common use, but improvements in design are made from time to time. Two recent developments in high speed steel cutters made by Goddard & Goddard Company, Detroit, Mich., are shown in the illustrations.

Inserted Tooth Mill

The inherent weakness in inserted blade cutters has generally been due to the fact that the blades were set radially in a soft steel body, the resulting radial cut consuming excessive power in removing metal; also, the severe use accorded these cutters often makes the soft steel body comparatively short lived.

In the inserted tooth mill, illustrated, maximum strength of tooth has been secured with maximum chip clearance. The blades are set at the same angle as in solid mills, giving a shearing action, which removes the maximum amount of metal with the minimum consumption of power. The body is made of alloy steel, heat treated to an elastic limit of approximately 105,000 lb. per sq. in., which, combined with

Goddard & Goddard Inserted Tooth Mill

extreme toughness, makes it able to withstand heavy feeds and speeds.

The blades are held in the body by the well known wedge pin method, thus giving maximum strength to the tongue of body metal between the teeth. In addition, the blades are positioned positively against lateral thrust by dowel

pins inserted in the periphery of the body. This arrangement also increases the life of the blades, as it will be noted that multiple notches allow three possible positions of the blades as they are ground down. The final setting of the blades maintains two-thirds of their length in the body of the cutter, thus giving adequate support. These cutters are made to be used in gangs, right and left, or bolted to a flanged spindle. They are recommended for work requiring cutters of 10 in. in diameter or larger.

Half Side Mill

The great volume of milling known as straddle work has usually been done by milling cutters provided with teeth on the periphery and both sides, the idea being that when the

Half Side Mill With Deeply Cut Teeth

inside counter of each mill in a gang becomes dull the cutters can be transposed and a double amount of work done with a set of cutters at one grinding. The half side mill illustrated has teeth on the periphery and one side only. It will be noted, however, that the peripheral teeth are on a spiral, as well as being undercut. The following advantages of this arrangement may be mentioned: Spiral peripheral teeth, undercut on both the peripheral and side teeth, and a patented tooth form, which provides maximum tooth strength and chip clearance. These factors combined produce easy shearing action at the point of the tooth, where the service is most severe. In fact, each tooth is practically a diamond point and removes its share of metal with the

same ease, freedom and finish as a diamond point properly ground and set in the toolpost of a lathe. Further reference to the illustration of the half side mill shows the side teeth to be much deeper than ordinary. This feature allows more grinding and adds to the ultimate life of the cutter more than is possible with the ordinary side mill.

Goddard & Goddard half side mills are made in sizes varying from 4 in. to 9 in. in diameter. The center holes vary in size from $1\frac{1}{4}$ in. to 2 in., these relatively large sizes being necessary on account of the heavy work for which the cutters were designed. Both milling cutters described in this article are made of high speed steel only.

Vertical Shaper for Tool and Die Work

THE manufacture of many tools, punches and dies for railway shop work involves certain machine operations that can be performed to good advantage on the vertical shaper illustrated. The machine is manufactured by the Hanson-Whitney Machine Company, Hartford, Conn., and especial care was taken to make it capable of rapid, accurate work. The ram travels rapidly and the entire shaper construction is rigid. Although of a comparatively small size, the machine has a large range and a large size die can be swung in all directions without interference. On the other hand, small tools for fine operations can be used.

In several respects the Hanson-Whitney vertical shaper differs from the type where a reciprocating ram is used for the action. Among other things the length of stroke can

does not drag on the work. Referring to the more detailed illustration, it is evident that no set screw or projecting obstacle on the tool holder prevents the ram from clearing the work. In other words, a long overhang of the tool is not necessary when planing the outside of a piece, and when planing the inside of a piece, such as a die, it is only necessary to have the overhang of the tool as long as the cut to be taken. The standard tool illustrated is made with a clearance and when sharpened needs to be ground only at the end. All working surfaces in connection with the clapper mechanism are made of hardened steel and ground.

Besides the rotary motion of the table, it can be tilted so that dies can be made with a clearance when desired. A segment, graduated in degrees, indicates the amount of taper that may be desired. The feed screws on the slides have micrometer dials graduated to .001 in. The machine is driven through a tight and loose pulley on the left hand side of the column and three speeds are provided. The fast

Hanson-Whitney Vertical Tool and Die Shaper

be adjusted whether the machine is running or still and with equal facility. This adjustment is made with the handwheel shown on the side of the column, near the top, the entire mechanism being of simple and durable construction.

An elk horn shaped handle, shown on the right side of the column, controls the starting and stopping and when the machine is stopped, the ram will automatically stop on the end of the up stroke. This will occur no matter when the handle is placed in the stopping position.

Another advantage is that the tool on the back-stroke positively recedes from the work and on the down-stroke positively engages with it. Therefore, the edge of the tool

View Showing Details of Tool Post and Double Gap Vise

driving pulley runs constantly, thus making it possible to drive the machine directly from the main shaft and eliminate a countershaft. An interlocking device prevents injury to the gears. The machine is controlled by the elk horn shaped handle, which operates an expanding friction clutch and drives the ram. About halfway down on the right side of the column there is a handwheel by means of which the machine can be turned by hand when setting up a piece of work, so as to make sure that there is no interference. As indicated, the knee is adjustable for positioning the stroke.

The stroke of the ram is $4\frac{1}{4}$ in. and the maximum difference from the table top to the end of the ram is $10\frac{1}{2}$ in. The diameter of the rotary table is 14 in., the longitudinal and transverse travel being 15 in. and 8 in., respectively. The table can be tilted up to five degrees. The number of strokes per minute for each speed are 66, 114 and 200. The work vise, illustrated, is furnished only when ordered. It is made for holding small pieces and a 2-in. and 4-in. gap has proved a great convenience in setting up small jobs.

Cooler for Lubricating and Quenching Oils

AN ingenious device for the cooling of oil used in lubricating turbine bearings, or quenching oil in the heat treating of steel, has been developed by the Griscom-Russell Company, New York. Circulation through the cooler maintains the oil at a constant temperature and permits the continued use of the original quantity of oil and its

This baffle also serves to bring the oil into intimate contact with the cooling surface and insures a high rate of heat transfer.

The shell is of cast iron and the tubes of seamless drawn brass or copper, expanded into a fixed tube plate at one end and into a floating head at the other. This permits expan-

Griscom-Russell Multiwhirl Cooler

maintenance at the proper viscosity for efficient results.

The apparatus takes its name from the whirling path of the oil, caused by the use of a helical baffle which directs the flow of oil without appreciably retarding its progress.

and contraction without strain on the tube joints. The cooling of quenching oil insures maintenance of the quenching bath at a fixed temperature and also permits the use of a cheaper grade of oil.

Cincinnati Geared Head Lathe

THE machine illustrated below is one of a line of geared head engine lathes manufactured by the Cincinnati Lathe & Tool Company, Cincinnati, Ohio, and previously described on page 174 of the March *Railway Mechan-*

ical Engineer. These machines are now being made with three different types of drive, including belt drive from the main line shaft, motor drive with the motor mounted at the side or rear of the head and the arrangement illustrated, in which

Cincinnati Lathe Provided with Hexagon Turret and Driving Motor on the Headstock

the motor is mounted on the headstock. This arrangement takes up a minimum of floor space, but in case the motor would interfere with overhead jib cranes or traveling cranes,

it may be placed either at the side or rear of the head and drive through a silent chain. The illustration shows the lathe equipped with a hexagon turret.

An Adaptable Drill Steel Furnace

WHILE the drill steel furnace illustrated was designed by the Sullivan Machinery Company, Chicago, Ill., especially for the efficient sharpening and tempering of drill steel used in mines and quarries, the field of usefulness of the furnace is not limited. Due to its general convenience and adaptability, it is suited for certain other heating purposes such as heating bars, bolts, rods, or coupling pins in railway shops.

In construction, the furnace consists of a rectangular cast iron box with a lining of firebrick having adjustable hearths and hoods, a burner or atomizer being attached at one end. The furnace is set at a convenient working height and an adjustable support carries the outer ends of the work. When it is desired to maintain a constant known temperature as in the hardening of steel, a pyrometer is used. A convenient arrangement of the pyrometer is shown in the illustration with the meter attached to the back wall.

Among the advantages of the Sullivan furnace may be mentioned the possibility of obtaining uniform temperatures without danger of overheating, large capacity, economy of fuel and compressed air, adaptability to different kinds of fuel such as oil or gas, flexibility providing for adjustment to heat any portion of the work desired, ease of adjustment and repair, and low cost of maintenance.

In operation, combustion takes place over the entire length of the combustion chamber of the furnace. The so-called cold end is that next the burner and the hot or finishing end is that farthest from the burner. With the furnace operating properly, an even flame is produced, a small portion of which comes up through the opening in the combustion chamber between the hearths at the hot end. The greater portion of

this flame, however, is confined in the combustion chamber and produces a uniform reflected heat on the work.

Sullivan Furnace and Pyrometer Installation

Self-Contained Motor-Driven Grinder

A NEW ball bearing grinding machine, driven by a self-contained 10-hp. motor, has been placed on the market by the Hisey-Wolf Machine Company, Cincinnati, Ohio. This machine, shown in the illustration, is designed to use two 24-in. grinding wheels, 4 in. wide. Friction

imity to the grinding wheels. The construction of the bearing housing is such as to permit correct mounting from

Hisey-Wolf Ball Bearing Grinding Machine

View Showing Quick Acting Switch and Adjustable Steel Guards

losses are reduced to a minimum by the use of SKF ball bearings mounted in the motor end caps, in close prox-

imity to the grinding wheels. The construction of the bearing housing is such as to permit correct mounting from the exterior of the motor, a feature which increases the efficiency of the bearings and holds the armature spindle per-

manently in correct alinement. The importance of this feature can hardly be overestimated.

The generous and rugged proportions of the machine reduce vibration to a minimum and enable it to stand up under heavy duty and produce a uniform finish on all work ground. Not only is the friction loss in the grinder reduced to a minimum, but it is claimed that a grinding wheel lasts longer because, after once being balanced, it does not require frequent dressing.

Each machine is fitted with a quick acting switch, as shown in the detailed illustration and the larger sizes of grinder have an automatic starter equipment. The operating handle is located as shown in front of the motor, with the switch proper completely enclosed in the bed. This

method of mounting insures protection and also permits ready access to all the switch mechanism by simply removing the cover plate.

Special attention is called to the wheel guards, which are made of steel to insure all possible protection. These guards enclose the grinding wheels for three-quarters of the circumference, are adjustable, and are so designed that the wheels can be removed independently. The water pot and pool tray are separate detachable units.

Arrangement can be made for either direct current or alternating current motor drive and in either case the motor is especially designed for the particular machine on which it is used. The Hisey-Wolf grinding machines are made in six sizes from $\frac{1}{2}$ hp. to 10 hp. capacity.

Short-Cut Lathe of Improved Design

A SHORT-CUT lathe with several important improvements not incorporated in the original machine has been placed on the market by the O. R. Adams Manufacturing Company, Rochester, N. Y. The lathe swings $13\frac{5}{8}$ in. and is designed to take 20 in. between centers. It has a single pulley drive through a geared head and six changes of speed are obtained through an operating lever and knob. The operating lever provides two changes, the lever being placed so that the lathe can be started and stopped without making it necessary for the operator to move from his position in front. The neutral position of the lever applies a brake to all revolving parts, bringing the spindle to rest immediately.

All gears in the head run in a bath of oil and are of steel with the exception of the large gear on the spindle. The spindle itself is made from a special grade of alloy steel, ground accurately to size. It runs in phosphor bronze bearings which are adjustable and has an SKF self-aligning ball bearing to take up the end thrust.

The carriage feeds are eight in number, obtained through a gear box with a tumbler gear, which provides four changes of feed. These vary from .006 to .025 with end gears in one ratio and a further range of feeds from .010 to .042 when the end gears are reversed. The carriage has power cross feed and the rate is indicated on the index plate mounted over the gear box. The direction of feed can be changed through a reverse lever mounted in a supplementary gear case at the headstock end of the lathe. All operating handles are conveniently located.

The carriage has a compound rest so arranged that it can be changed to either a four sided turret toolpost, combined

front and rear tool rest or plain rest, without any additional fitting. The apron is of the double plate type with the two halves in contact, thus forming a box section of strength and

Adams Short-Cut Lathe

rigidity. Each lathe is supplied with an oil pan bed of sufficient size to prevent any cutting compound getting on the floor.

Universal Shaper With Unit Gear Box

THE 24-in. universal shaping machine described in this article is made by the Potter & Johnston Machine Company, Pawtucket, R. I., and particular attention is called to the gear box, which is a unit within the base of the machine. All the universal features necessary for die and tool work have been incorporated in the machine, which is at the same time well adapted for general manufacturing purposes or repair shop service. All control handles are on the right hand side of the shaper.

A heavy column, of correct design to withstand all ordinary strains, is securely fastened to the base of the machine. The total length of the base is 34 in. A large gear gives reciprocating motion to the ram by means of a wrist pin carried in a disk set eccentric in the gear. A graduated dial on the outside of the machine provides for adjustment

to give different lengths of stroke. The ram is held securely down to its seating by means of rectangular straps on top of the column. A rectangular gib on one side of the ram provides for taking up wear.

Power down feed for the tool head is operated by the movement of the ram against an adjustable feed cam dog, located along the side of the ram. This cam is capable of adjustment while the ram is in motion to obtain practical variations in the amount of feed. An adjustable stop at the side of the ram positively controls the down feed of the tool slide to any predetermined point. The table can be swiveled around a central pivot and is revolved by means of a worm carried in the table and engaging in teeth cut in the periphery of the pivot. One side of the table has an auxiliary tilting portion for obtaining compound angles. The

cross slide is exceptionally deep and accurately scraped to its bearing against the column. The table and cross slide are elevated and lowered by means of a power operated

base. Five speeds are obtainable by a movement of the shipper lever, which is located conveniently for the operator. The machine can be supplied with either motor drive or

Potter & Johnston Universal Shaper

Rear View Showing Motor Drive

screw. The weight of these parts is carried on a ball bearing surrounding the elevating screw.

The gear box provided with the shaper is a unit with the

single pulley drive. When motor drive is desired, a 5-hp. constant speed motor is recommended, the drive being through a silent chain.

Snap Thread Gages for Accurate Inspection

A SNAP thread gage for accurate inspection of numerous threaded parts has been developed by the Herrmann Gauge Company, Detroit, Mich. This gage is shown in Fig. 1, which also indicates the adjustable jaws. For many purposes the snap thread gage has important advantages over the plug type thread gage. Its use eliminates the necessity of catching the thread and screwing the work into the gage and with the snap gage, all of this time is saved. In operation, it is used like the snap gage on cylindrical

thread gages are made in sizes from 1/4 in. to 3 in. and with a variation of pitch from 8 to 27.

The snap gage designed for use as a limit gage is shown in Fig. 2. This tool can be used to good advantage in test-

Fig. 1—Herrmann Snap Thread Gage

Fig. 2—Limit Snap Thread Gage

work. Since the work is not screwed into the gage, wear does not take place as usual, and it has been found that the size is maintained indefinitely. The blades are made of hardened steel and will last a long time.

Because the parts are simple, the working surfaces can be accurately cut and lapped to any desired shape. Both jaws are made adjustable, as indicated in the illustration, and can be sealed to prevent a change in the setting. These snap

ing threaded work where it is desired to maintain the accuracy within two set limits. The limit gage is made in the same sizes as the snap thread gage.

Hydraulic Rail Bender of 35 Tons Capacity

THE hydraulic rail-bending press illustrated was designed and built recently by the Hydraulic Press Manufacturing Company, Mt. Gilead, Ohio. As indicated, the press is of the horizontal type on wheels, and can be moved readily to any desired point. The capacity is 35 tons pressure. While of comparatively light construction, the press is rigid and of ample strength for the severest kind of service likely to be required of it. Four cast steel strain rods are rigidly attached to the double I-beams, the latter being formed like clevises at their outer ends. Steel hinge pins at the bottom and steel locking pins at the top pair of strain rods provide for connecting the two steel resistance heads when bending a rail. Each of the bottom strain rods has a steel roller mounted in such a way that when a rail is in the press it may be moved easily, in order to apply the pressure at different points.

The press is fitted with a class DD hand pump, spring safety release valve and a T-screw operating valve. The pump may be used for either high or low pressure. The low pressure may be used until the bending block meets the rail and the operator cannot work the pump, then the high pressure is used. The T-valve is closed when the pressure is applied and opened when the pressure is to be released. The spring pull-back device, which is enclosed in the two small sized cylinders, returns the ram to its initial

position. In case a gage should be desired on the pipe line, it may be attached at the upper connection of the T-screw valve.

Portable Hydraulic Rail Bender of Improved Design.

Potter & Johnston Vertical Type Automatic

IN addition to a horizontal automatic, the Potter & Johnston Machine Company, Pawtucket, R. I., has placed on the market a vertical type of automatic chucking and turning machine designed to meet the demands of manufacturers having limited floor space. On all machines there are five combinations of three automatic variations of speed, giving fifteen spindle speeds in geometric progression from 14.3 r.p.m. to 140 r.p.m.

There are nine combinations of two automatic variations of feed giving eighteen feeds from .005 to .066 in. per revolution, and a threading and reaming feed from .050 to .125 in. per revolution, which allows the cutting of threads from 8 to 20 per in. The feeds are independent of the high constant speed for idle movements of the turret slide, while withdrawing and advancing the tools to the point of cutting.

The cross slide has a feed of 5 in. each way. The right and left hand side of the cross slide operate independently by screw feed, and can be arranged to feed into the work at any predetermined time, and at any desired relation one to the other.

The turret slide is of rugged construction and travels on ways so designed that all wear will be even and will not affect the accuracy of the machine. The turret slide has 14 in. feed and no allowance needs to be made for revolving as the turret revolves at the extreme end of its travel.

A 16-in. three-jaw scroll chuck is regularly furnished with each machine. This chuck is provided with a pilot bushing to receive pilot bars for supporting the tools during the cutting operations. The chuck jaws are operated by a pilot wheel at the front of the machine, which has been designed so that while the operator is using the pilot wheel it is impossible to throw in the feed, thereby eliminating danger of accident. The oil pump and piping and oiling arrangement through the turret are furnished on machines handling material requiring a lubricant.

As the machine is equipped with a single pulley drive, the motor application is simple. The motor is mounted on

the upright at the rear of the machine, and the connection is by belt to the driving pulley. A 7½ hp., constant speed motor is recommended, and through change gears the same variation of speeds and feeds are obtainable as on the belt-driven machine.

Potter & Johnston Vertical Automatic Chucking and Turning Machine

The Potter & Johnston vertical automatic has a swing over the ways of 23 in. and over the cross slide of 16 in. The turret has four faces. The holes in the turret are $2\frac{1}{2}$ in. in diameter by $4\frac{1}{2}$ in. deep. The distance from the center of the turret to the top of the turret slide is $4\frac{1}{2}$ in., the maximum travel of the turret slide being 14 in. The turret

feed is 14 in. and the turret slide adjustment 8 in. The length of turret slide travel, which permits of supporting or piloting tools, is 14 in. A minimum amount of space is required for this machine, due to the fact that the maximum width and length of bed are only 40 in. and 59 in., respectively. The total height of the machine is 8 ft. above the floor.

General Purpose Automatic Extension Reel

AMONG other uses, the automatic extension reel illustrated has proved of value in increasing the life of insulated electric cord used as extensions for portable drills, grinders and fans, as well as electric lights. Any one familiar with railway shops and especially railway shop tool rooms where the electric light cords are received after each day's work, will remember the frayed and worn appearance of many cords. Under the severe use accorded them, which includes pulling over the erecting shop floors and rolling trucks over them, the life of electric light cords is often short.

Not only do the ordinary extension cords have a relatively short life, but it is necessary to maintain an extra large number in stock due to the fact that in railway shops, forehanded mechanics anticipate the occasional need to light a dark corner by keeping extension cords and lights in their boxes. This condition can be remedied by installing an automatic reel permanently in the dark corner referred to.

Among the advantages of the automatic extension reel may be mentioned: longer life for the cord, light, fuses and guards; less danger of fire due to short circuits; and more convenience in operation due to the slack cord being rolled up at all times.

The reel is of simple, durable construction, and its actual size is 9 in. in diameter by 2 in. wide. It is equipped with 25 ft. of reinforced weatherproof cord. The head is provided with a swivel joint, enabling the lamp to be carried in any direction from the reel, while an automatic lock permits a positive stop at any desired point. It is insulated to withstand a test of 1,250 volts. In operation, the light or motor is taken in the operator's hand and carried to the desired distance, when a slow motion backwards causes the automatic lock to catch and hold the cord at that point. To release, a slight pull is given on the cord. This unlocks the catch and the cord is automatically rewound as the operator

Autex Automatic Extension Reel

walks towards the reel, with lamp or motor in hand. The device is manufactured by the Cincinnati Specialty Manufacturing Company, Inc., Cincinnati, Ohio.

Independent Pneumatic Motor Hoists

PNEUMATIC motor hoists of one-half, one and two tons capacity have been placed on the market by the Independent Pneumatic Tool Company, Chicago, Ill. These hoists are made with two different lifts as follows: $\frac{1}{2}$ -ton and 1-ton hoists, 20 and 40 ft.; 2-ton hoist, 20 and 10 ft. The speed of lift for the $\frac{1}{2}$ -ton, 1-ton and 2-ton hoists is 32, 16 and 8 ft. per min., respectively, and the air consumption is 1.9, 3.8 and 7.6 cu. ft. per foot lift, respectively.

Equipped with a large worm gear drive, the worm is cut to a pitch that locks the drum and holds the load at any required point, even when the air is turned off, or the air line breaks. If necessary, the motor can be taken out for repairs while the load is suspended. An automatic stop prevents injury to the load or hoist by shutting off the air just before the cable is fully wound or unwound. The automatic stop can be adjusted or set for any lift, long or short, within the capacity of the hoist. The drum cover contains

a permanent eyelet for the temporary cable used in placing the hoist in position, thus leaving the hook free for permanent attachment.

The throttle valve of the motor has a graduated opening, which makes it easy to control the speed of the motor and start or stop it gradually. The motor is reversed by shifting an eccentric, operated by the chains. The cables and drums are placed far apart to prevent the load from twisting or turning. The drums are spirally grooved and a guide on each drum leads the cable into the spiral groove and prevents climbing, crossing and cutting. The cable is protected by the drum covers and attached to the drum with a large radius bend, to prevent its kinking or weakening under heavy strain.

The motor is of the close-quarter drill type and has a relatively small air consumption. The cylinders are double acting and use a single throw balanced crank shaft, which is connected with the worm.

Electric Rivet Heaters for Railway Shops

ELECTRIC rivet heaters possess certain inherent advantages which may cause them to be used extensively in the railroad field. Three of these machines have been recently placed on the market. These are, respectively, the Berwick rivet heater, manufactured by the American Car and Foundry Company, New York; the Humil heater, manufactured by the Humil Corporation, New York, and the General Electric heater, manufactured by the General Electric Company, Schenectady, N. Y.

The three machines differ somewhat in details of design, but are similar in principle. They are all of the electric conduction type; the rivets are heated by the passage of an electric current through them. Electrically, the rivet heaters consist of a specially designed transformer. The secondary terminals are heavy copper blocks, between which the rivets to be heated are placed. Suitable means are provided for controlling the current. In the Berwick and Humil ma-

Rivets can be heated, cooled and reheated a number of times without harmful oxidation and as many as 1,400 rivets can be heated in an hour with a single machine, the hourly

A Two-Head General Electric Rivet Heater

chines the rivets being heated are connected in multiple, while in the General Electric machine two rivets are connected in series.

The operation of heating rivets is very simple. The copper blocks which form the secondary terminals are forced apart by a handle or foot treadle, a rivet is placed endwise between the blocks, and on releasing the handle or treadle the blocks are made to grip the rivet by their weight or by springs, depending on the type of machine. A stop prevents the blocks from coming in contact with each other when there is no rivet between them.

The electric furnace is clean, gives off no objectionable gas and the rivets are always in plain view of the operator. The rivet is heated from the inside and the shank becomes hotter than the head, due to its lesser cross section. These are ideal upsetting conditions, as the heat is applied exactly where it is needed, and the head, being cooler, is less malleable and is therefore less likely to be marred by the backing up tool.

A Three-Head Berwick Rivet Heater

capacity depending upon the size of rivet and the number of heating heads on the machine. The machines are built to operate on alternating current supply voltages from 110 to

A Four-Head Humil Rivet Heater

550; but there is no danger to the operator, as the voltage across the secondary terminals of any of the machines is never more than ten volts. From five to seven pounds of rivets can be heated with a power consumption of one kw. hour.

neering. Applications should be in the hands of V. R. Hawthorne, secretary, Chicago, not later than June 15. In case there are more than two applicants the scholarships will be given to the two passing the entrance examination with the highest standing. Full information will be supplied by the secretary upon application.

Screw Machine vs. Turret Lathe

The Warner & Swasey Company, Cleveland, Ohio, announces a campaign for discontinuing the name "screw machine" when applied to the modern turret lathe. It is explained that the name "screw machine" is no longer appropriate when applied to the modern turret lathe, which is now seldom used for the making of screws, as automatic screw machines of various types serve this purpose better when large quantities are involved. Ten years ago bar work was the main product handled on what was then known as a hand screw machine; but to-day there is more chucking work performed on the turret lathe than bar work. Furthermore, the modern turret lathe is designed and constructed to handle heavy castings and forgings and is provided with sufficient power for machining tough forgings and alloy steel parts. For use merely for making screws, the present power provided in turret lathes would be superfluous.

The Warner & Swasey Company is urging all users and manufacturers to aid in the campaign for dropping the old term "screw machine" when applied to turret lathes.

English Rolling Stock to Be Standardized

Sir Eric Geddes, Minister of Transport, recently outlined the plans of the Ministry of Transport with regard to standardization on the English railroads. He said that the mechanical engineering department of the Ministry was endeavoring to standardize the freight cars, and a commencement had been made by arranging with all railways and all owners of cars that all running gear should conform to certain standards. With regard to the cars themselves, there is not the least doubt that for certain classes of traffic the object to be aimed at is a car of much higher capacity, for this will lead to a great saving in the weight and length of trains, and consequently in the length of new sidings. Larger cars are not, of course, suitable to all kinds of traffic but for coal traffic they would be of enormous value. In deciding on the size of the car to be used, consideration must be given to existing conditions, to the cost of the alterations to be made in the right of way and structures and what economies would result.

As to the standardization of locomotives, Sir Eric Geddes says this is at present limited by the capacity of bridges and roads already built to carry locomotives of a certain size and therefore at present two or even three classes in each type might be allowed for, say light and heavy, or light, medium and heavy, of which parts could be interchangeable and a considerable reduction effected in the number of types.

The mechanical engineering department is also considering the standardization of signaling apparatus, economies in workshops, improvement in the plant and equipment of docks, and economy in the production and use of everything of a mechanical nature connected with transport.

The Mechanical Conventions

The record-breaking attendance which is expected at the Atlantic City conventions has exhausted the reservations at many of the hotels. J. D. Conway, secretary of the Railway Supply Manufacturers' Association, has offered to be of assistance in the matter of securing accommodations and suggests that those who have not yet secured their reservations might find it of value to communicate with his office at 1841 Oliver building, Pittsburgh.

The Supply Association has arranged to have the Hotel Esplanade which is directly beyond the Chelsea opened for the convention. This hotel does not regularly open until July 1. It has 250 rooms with 60 private baths, running water in all rooms and swimming pool in hotel. American plan rates \$6 to \$10 a day.

There are many good hotels located off the boardwalk, among which are the Wilshire, Craig Hall and the Grand Atlantic.

For those stopping at hotels located some distance from the pier there is good jitney service on Atlantic avenue, one block from the board-walk, where jitneys run every two or three minutes. The fare is 5 to 10 cents and from the Hotels Esplanade or Breakers to the pier is covered in five minutes.

Calendar for the June Convention

The following is the program for the second annual meeting of the American Railroad Association, Section III—Mechanical, to be held at Atlantic City, June 9 to 16, inclusive:

WEDNESDAY, JUNE 9, 1920

Prayer	A.M. 9.30 to 9.40	A.M.
Address of welcome by mayor of Atlantic City.....	9.40 to 10.00	
Address by the chairman	10.00 to 10.30	
Action on minutes of annual meeting of 1919.....	10.30 to 10.35	
Appointment of committee on subjects, resolutions, correspondence, obituaries, etc.....	10.35 to 10.45	
Unfinished business	10.45 to 10.50	
New business	10.50 to 11.00	
Report of general committee, including announcement of nominations for members of nominating committee.....	11.00 to 11.15	
Discussion of reports on:		
Nominations	11.15 to 11.30	
Mechanical Stokers	11.30 to 12.00	M.
Modernization of Stationary Boiler Plants.....	12.00 to 12.30	P.M.

THURSDAY, JUNE 10, 1920

Discussion of reports on:	A.M.	A.M.
Fuel Economy and Smoke Prevention.....	9.30 to 10.00	
Auxiliary or Safety Connections Between Engine and Tender	10.00 to 10.30	
Design, Maintenance and Operation of Electric Rolling Stock	10.30 to 11.00	
Scheduling and Routing Systems for Locomotive Repair Shops	11.00 to 11.30	M.
Superheater Locomotives	11.30 to 12.00	P.M.
Individual paper on "Snow Fighting Apparatus," by W. H. Winterrowd	12.00 to 12.30	

FRIDAY, JUNE 11, 1920

Discussion of reports on:	A.M.	A.M.
Locomotive Headlights and Classification Lamps.....	9.30 to 10.00	
Fed Water Heaters for Locomotives.....	10.00 to 10.30	
Individual paper on "Locomotives as a Big Investment," by G. M. Basford	10.30 to 11.00	
Discussion of reports on:		
Design and Maintenance of Locomotive Boilers.....	11.00 to 11.30	M.
Engine Terminals, Design and Operation.....	11.30 to 12.00	P.M.
Train Resistance and Tonnage Rating.....	12.00 to 12.30	

MONDAY, JUNE 14, 1920

Discussion of reports on:	A.M.	A.M.
Autogenous and Electric Welding.....	9.30 to 10.00	
Specifications and Tests for Materials.....	10.00 to 10.30	
Standard and Recommended Practice.....	10.30 to 10.45	
Election of officers.....	10.45 to 11.00	
Discussion of reports on:		
Repair Shop Layouts.....	11.00 to 11.20	
Amalgamation	11.20 to 11.30	
Standard Blocking for Cradles of Car Dumping Machines.....	11.30 to 11.40	P.M.
Standard Method of Packing Journal Boxes.....	11.40 to 12.10	P.M.
Establishment of a Co-operative Research Bureau.....	12.10 to 12.30	

TUESDAY, JUNE 15, 1920

Discussion of reports on:	A.M.	A.M.
Revision of Passenger Car Rules of Interchange.....	9.30 to 10.00	
Prices for Labor and Materials.....	10.00 to 10.30	
Depreciation for Freight Cars.....	10.30 to 11.00	
Arbitration	11.00 to 11.30	M.
Tank Cars	11.30 to 12.00	P.M.
Brake Shoe and Brake Beam Equipment.....	12.00 to 12.30	

WEDNESDAY, JUNE 16, 1920

Discussion of reports on:	A.M.	A.M.
Couplers and Draft Gear.....	9.30 to 9.50	
Car Wheels	9.50 to 10.20	
Car Construction	10.20 to 10.50	
Safety Appliances	10.50 to 10.55	
Loading Rules	10.55 to 11.20

National Screw Thread Commission Report Approved

The progress report of the National Screw Thread Commission, Washington, has been approved by the commission and is now available. The report covers the standardization of only those threads, sizes, types, and systems which are of paramount importance by reason of their extensive use and utility. Information is given to permit the writing of definite and complete specifications for the purchase of screw thread products, and the application of the specifications is explained in detail.

It is recommended by the commission that the United States standard or Sellers' profile, hereafter to be known as the National Form of Thread, be used for all screw thread work except where otherwise specified for special purposes. The coarse thread series recommended are the present United States standard threads supplemented in the sizes below 1/4 in. by the standard established by the American Society of Mechanical Engineers. The fine thread series consists of sizes taken from the standards of the Society of Automotive Engineers and the fine thread series of the American Society of Mechanical Engineers.

The report establishes for general use four distinct classes of screw thread fits with subdivisions which, together with specifications, are explained as for the purpose of insuring the interchangeable manufacture of screw thread parts throughout the country. Tolerances are given for loose fit, medium fit (regular and special), and close fit. Extensive tables give the tolerances and dimensions for each class of fit. Tolerances and dimensions are included for fire hose couplings and small hose couplings. A complete gaging system which has been found adequate in the production of war material is specified in detail.

Standard Sizes for Shafting

The Council of the American Society of Mechanical Engineers has approved the report of a committee formed to investigate the standardization of shafting sizes and has accepted the following lists of sizes as recommended standards for the society:

Transmission Shafting:

15/16 in.; 1-3/16 in.; 1-7/16 in.; 1-11/16 in.; 1-15/16 in.; 2-3/16 in.; 2-7/16 in.; 2-15/16 in.; 3-7/16 in.; 3-15/16 in.; 4-7/16 in.; 4-15/16 in.; 5-7/16 in.; and 5-15/16 in.

Machinery Shafting:

Size intervals extending to 2 1/2 in., by sixteenth inches; from 2 1/2 in. to 4 in., inclusive, by eighth inches; from 4 in. to 6 in., by quarter inches.

These standard sizes have also been approved by representatives of the following associations: American Hardware Manufacturers' Association, American Railway Engineering Association, American Supply & Machinery Manufacturers' Association, National Association of Manufacturers of the U. S. A., National Association of Purchasing Agents, National Machine Tool Builders' Association, Southern Supply & Machinery Dealers' Association.

It was the opinion of the committee that the adoption of standard sizes of shafting will mean that in the future there will be a gradual elimination of odd sizes from makers' lists and from dealers' stocks, and for new construction only standard sizes would be selected.

MEETINGS AND CONVENTIONS

Association of Railway Electrical Engineers.—The semi-annual meeting of this association will be held at the Hotel Dennis, Atlantic City, on June 14. The meeting will be called to order at 9 a. m. Progress reports will be presented by committees on truck and tractors; electric welding; illumination; train lighting equipment and practice; railway stationary power plants; electric headlights; electrification; electric repair shop facilities and equipment.

American Railroad Master Tinnners', Coppersmiths' & Pipefitters' Association.—At the convention of this association, which will be held June 1-4 at the Hotel Sherman, Chicago, the following subjects will be discussed: Headlights and their maintenance, locomotive jackets, manufacturing in locomotive tin shops, steam heat and its upkeep, acetylene welding in the tin shop, spot welding in the tin shop, repairs to steel coaches, methods of babbiting, reclamation of scrap sheet metal, air brake piping.

American Society for Testing Materials.—This society will hold its twenty-third annual meeting at Asbury Park, N. J., on June 22 to 25 inclusive, with headquarters at the New Monterey hotel. The first session will be held at 10 a. m., Tuesday, June 22. Papers and reports will be presented at the various sessions in accordance with the following general outline:

- Tuesday morning.....Non-Ferrous Metals.
- Tuesday afternoon.....Wrought and Malleable Iron and Corrosion.
- Tuesday evening.....Presidential address and reports of administrative committees.
- Wednesday morning...Steel.
- Wednesday afternoon...Committee meetings.
- Wednesday evening.....Testing Apparatus.
- Thursday morning.....Preservative Coatings and Lubricants.
- Thursday afternoon.....Miscellaneous Committee Reports and Papers.
- Thursday evening.....Ceramics.
- Friday morning.....Road, Materials, Lime and Gypsum.
- Friday afternoon.....Golf tournament
- Friday evening.....Cement and Concrete.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago. Convention, June 9-16, 1920, Atlantic City, N. J.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.—J. P. Murphy, N. Y. C., Collinwood, Ohio. Convention June 14-16, 1920, Atlantic City, N. J.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. B. Baker, Terminal Railroad, St. Louis, Mo. Convention June 1-4, 1920, Hotel Sherman, Chicago.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, Belt Railway, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa. Annual meeting, June 21, 1920, New Monterey Hotel, Asbury Park, N. J.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreuccetti, C. & N. W., Room 411, C. & W. Station, Chicago.
- CANADIAN RAILWAY CLUB.—W. A. Booth, 131 Charron St., Montreal, Que. Meetings second Tuesday in month, except June, July and August.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 North Pine Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koeneke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings second Friday in January, March, May and September and second Thursday in November, Hotel Statler, Buffalo, N. Y.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—J. C. Keene, Decatur, Ill.
- CINCINNATI RAILWAY CLUB.—H. Boutet, 101 Carew Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, C. H. & D., Lima, Ohio.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 542 W. Jackson Blvd., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention Sept. 7-10, 1920, Hotel Sherman, Chicago.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass.
- NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Meetings second Tuesday in month, except June, July, August and September.
- NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings third Friday in month, except June, July and August, 29 W. 39th St., New York.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings, third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings, second Thursday in month, alternately in San Francisco and Oakland.
- RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings, fourth Friday in month, except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.—J. B. Frauenthal, Union Station, St. Louis, Mo. Meetings, second Friday in month, except June, July and August.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Cleveland, Ohio.
- WESTERN RAILWAY CLUB.—J. M. Byrne, 916 West 78th St., Chicago. Meetings, third Monday in month, except June, July and August.

PERSONAL MENTION

GENERAL

A. S. ABBOTT has resigned as supervisor of tools of the St. Louis-San Francisco, at Springfield, Mo., to become superintendent of motive power of the Miami Mineral Belt at Miami, Okla.

GEORGE S. EDMONDS, recently appointed acting superintendent motive power of the Delaware & Hudson, with headquarters at Colonie, N. Y., has been appointed superintendent motive power, succeeding James H. Manning, deceased. Mr. Edmonds was graduated from Cornell University in 1895. He began railroad work shortly after graduation, in the shops of the New York Central and afterwards served in the road and mechanical engineer's office. He went to the Delaware & Hudson in 1900 as mechanical engineer and was appointed master mechanic in 1905, retaining that position until 1912 when he was appointed shop superintendent. On April 5, 1920, he became acting superintendent motive power and was promoted to superintendent motive power on April 21.

ERNEST V. WILLIAMS, shop superintendent of the Buffalo, Rochester & Pittsburgh, has been appointed superintendent motive power with headquarters at DuBois, Pa., succeeding F. J. Harrison, deceased. Mr. Williams served as apprentice at the Brooks Locomotive Works, Dunkirk, N. Y., and afterwards worked as machinist for the Rome Locomotive Works, Rome, N. Y., prior to beginning railroad work. He then entered the employ of the New York Central as machinist at West Albany, N. Y. Shortly afterwards he was promoted to assistant machine shop foreman at the same place and then to assistant to the superintendent of shops. His next position was that of machine shop foreman, also at West Albany. Later he was transferred to Depew, N. Y., as assistant general foreman, but afterwards he returned to West Albany as general foreman. He went to the Buffalo, Rochester & Pittsburgh on June 1, 1917, to accept an appointment as shop superintendent, the position he filled at the time of his recent promotion.

E. V. Williams

WALKER D. HINES has resigned as director general of railroads, effective May 15, and after a vacation trip abroad he plans to resume the practice of law in New York city. John Barton Payne, Secretary of the Interior, has been appointed to succeed Mr. Hines as director general, to have charge of the liquidation of the Railroad Administration and to act as the agent designated in Section 206 of the Transportation Act. In accepting Mr. Hines' resignation the President wrote that he could not let the director general retire without telling him how he had "personally valued and admired the quite unusual services you have rendered the government and the country." Mr. Hines has been

connected with the Railroad Administration since its organization. He was first appointed assistant to the director general and later, when Mr. McAdoo left Washington for an extended trip, he was appointed assistant director general and left in direct charge of the organization at Washington. He was appointed director general to succeed Mr. McAdoo on January 11, 1919. Prior to federal control he was chairman of the board of the Atchison, Topeka & Santa Fe and a member of the law firm of Cravat, Henderson & de Gersdorff.

JOHN M. KINCAID, electrician foreman of the Erie at Hornell, N. Y., has been appointed electrical supervisor for the Hornell region, with office at Hornell.

F. P. PFAHLER, who has been chief mechanical engineer of the Railroad Administration with office at Washington, D. C., has returned to the service of the Baltimore & Ohio as supervisor of locomotive maintenance, with office at Baltimore, and also the mechanical member of a committee appointed to investigate the feasibility of electrifying one or two of its divisions.

F. W. RHUARK has been appointed mechanical superintendent of the Pittsburgh & West Virginia. Mr. Rhuark was formerly master mechanic of the Baltimore & Ohio, eastern lines with headquarters at Connellsville, Pa.

EDWARD A. SWEELEY, a member of Railway Board of Adjustment No. 2, of the Railroad Administration, has resigned to become mechanical superintendent of the Fruit Growers' Express.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

E. BOWIE has been appointed division master mechanic of the Brownville division of the Canadian Pacific, with headquarters at Brownville Junction, Me., succeeding W. Wright, transferred.

HARRY L. GETTYS has been appointed master mechanic of the Virginian, with headquarters at Roanoke, Va. He was born on June 16, 1876, at New Hope, Pa., and was graduated from Roanoke High School in 1892. On October 1 of that year he began railroad work in the boiler department of the Norfolk Western and afterwards served a machinist apprenticeship. During the Spanish-American war he enlisted in the United States Navy and afterwards until August, 1905, was in the employ of the government at the Washington Navy yard. He then returned to the Norfolk & Western and was appointed rod gang foreman in 1907, assistant general foreman at West Roanoke in 1908, and from 1909 to 1913 did special work in connection with the cost of handling locomotives. He was then appointed chief inspector of new locomotive construction with the title of mechanical inspector, remaining in that position until 1917. On February 1, 1918, he entered the employ of the Nathan Manufacturing Company, but on March 15, 1920, accepted his present position as master mechanic of the Virginian at Roanoke.

J. E. GOODMAN, who was granted leave of absence a few months ago, has resumed his duties as master mechanic of the Lake Superior division of the Northern Pacific with headquarters at Duluth, Minn. and John A. Marshall, who served as acting master mechanic during Mr. Goodman's absence, has resumed his position as road foreman of engines at Duluth.

A. HAMBLETON, general foreman of the Chicago, Rock Island & Pacific shops at Shawnee, Okla., has been appointed master mechanic at Eldorado, Ark., succeeding W. M. Wilson, resigned to accept service with the Locomotive Firebox Company, Chicago.

C. E. McMILLEN has been appointed road foreman of engines on the Eastern division of the Atchison, Topeka & Santa Fe, with headquarters at Argentine, Kan.

J. K. NIMMO, assistant general boiler inspector of the Western district, Eastern lines, Atchison, Topeka & Santa Fe, has been appointed acting master mechanic of the Oklahoma division, with headquarters at Arkansas City, Kan., succeeding W. J. Hill, assigned to other duties.

VERN C. RANDOLPH has been appointed general supervisor of locomotive operation for the Hornell region of the Erie, with headquarters at Hornell, N. Y.

GEORGE W. RANKIN, formerly assistant master mechanic of the Louisville terminal of the Louisville & Nashville, has been appointed assistant master mechanic at the South Louisville shops of the same road. Mr. Rankin is 32 years old and was born in Pennsylvania. He received his education in the Louisville, Ky., schools, and is a graduate of the manual training high school of that city. He served an apprenticeship in the shops of the Louisville & Nashville, which he completed in 1909 and was subsequently promoted to the position of foreman. He acted in that capacity until 1917, when he was appointed assistant master mechanic of the

G. W. Rankin

Louisville terminal, and on March 1, 1920, received his present appointment.

A. R. TEAGUE has been appointed master mechanic of the Mobile division of the Mobile & Ohio at Whistler, Ala., succeeding G. L. Lambeth.

FRED L. VOERGE has been appointed assistant master mechanic of the Montana division of the Northern Pacific, with headquarters at Livingston, Mont.

W. WRIGHT has been appointed division master mechanic of the Farnham division of the Canadian Pacific, with headquarters at Farnham, Que., succeeding R. Walton, transferred.

CAR DEPARTMENT

GLENN A. ALLEN, supervisor of locomotive operation of the Erie at Susquehanna, Pa., has been appointed supervisor of air brakes, with headquarters at Hornell, N. Y.

JOHN F. SOMMERS has been appointed supervisor of car repairs of the Erie, at Hornell, N. Y.

SHOP AND ENGINEHOUSE

H. G. BECKER, general foreman of the Delaware & Hudson at Colonie, N. Y., has been appointed shop superintendent to succeed G. S. Edmonds.

GEORGE GOLDSMITH has been appointed shop superintendent of the Erie at Buffalo, N. Y.

HUMPHRIES W. BREWER, general foreman of the Buffalo, Rochester & Pittsburgh, at DuBois, Pa., has been appointed superintendent of shops at that point, succeeding E. V. Williams. Mr. Brewer was born on December 19, 1881, at Corning, N. Y., where he attended the public schools. On October 12, 1898, he began a machinist apprenticeship with the

Fall Brook Railroad at Corning, which he completed after this road was merged with the New York Central. He was then transferred to the Avis shops of the latter road as a mechanic, later being promoted to foreman. Subsequently he went to West Albany and acted as foreman there until July, 1917, when he resigned to accept the position of general foreman of the Buffalo, Rochester & Pittsburgh at DuBois, which he held until he received his recent appointment.

PURCHASING AND STOREKEEPING

G. W. BICHLMEIR has been appointed purchasing agent of the Kansas City Southern, with office at Kansas City, Mo., succeeding W. S. Atkinson, resigned.

D. C. CURTIS, prior to federal control inspector of stores on the Chicago, Burlington & Quincy, and during federal control storekeeper for the Northwestern Regional Purchasing Committee, has been appointed general storekeeper of the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee shops, Wis., succeeding F. J. O'Connor, who has been assigned to other duties.

W. J. DIEHL, general storekeeper of the Mobile & Ohio, with headquarters at Mobile, Ala., has been appointed purchasing agent, with the same headquarters, succeeding J. A. Turner, resigned. The office of general storekeeper has been abolished.

G. W. LEIGH, assistant general storekeeper on the Minneapolis, St. Paul & Sault Ste. Marie, at Minneapolis, Minn., has been appointed general storekeeper, with the same headquarters, succeeding T. W. Flannagan, promoted.

W. A. SUMMERHAYS, assistant purchasing agent of the Illinois Central, with headquarters at Chicago, has been appointed purchasing agent, with the same headquarters.

E. W. THORNLEY, formerly supervisor of stores, United States Railroad Administration, has been appointed assistant purchasing agent of the Baltimore & Ohio, with headquarters at Baltimore, Md.

OBITUARY

CHARLES F. JACOBSON, motive power inspector for the New York Central Lines in the fourth inspection district, with headquarters at Elkhart, Ind., died at his home in Elkhart on March 25.

GEORGE H. GILMAN, master car builder of the Northern Pacific, with headquarters at St. Paul, Minn., died on February 27 after a short illness. Mr. Gilman was born at McArthur, Ohio, on April 11, 1862. He began railroad work as a car carpenter on the Northern Pacific when 22 years old. In October, 1884, shortly after entering the employ of that road, he was promoted to car foreman. While serving in that capacity he was transferred several times to different places. He was appointed shop superintendent and master car builder at the Como shops in 1903, and on November 26, 1905, his title was changed to master car builder.

THOMAS J. BURNS, superintendent rolling stock of the Michigan Central, with headquarters at Detroit, Mich., died in that city on April 18. Mr. Burns was born at Hillsdale, Mich., on July 24, 1868. He graduated from Assumption College and spent some years at Grand Seminary, Montreal. His first railroad work was as clerk in the maintenance of way department of the Michigan Central at Bay City, Mich. He became engine dispatcher on November 1, 1896, and was appointed chief clerk to the master mechanic at Jackson, Mich., on December 15, 1902. In August, 1905, he was transferred to Detroit, Mich., as chief clerk to the superintendent motive power, and was appointed assistant superintendent motive power on June 1, 1912. In 1915 he was appointed to the position he held at the time of his death.

SUPPLY TRADE NOTES

The Grip Nut Company, Chicago, has opened a new plant at 5917 Western avenue, Chicago.

Arthur Benedict Bellows, first vice-president of the Pittsburgh Testing Laboratory, Pittsburgh, Pa., died on April 17.

The United States Gauge Company has moved its general sales office from 67 Wall street, to 37-39 Liberty street, New York.

Roger C. Sullivan, chairman of the board of directors of the Independent Pneumatic Tool Company, Chicago, died on April 14.

A. C. Moore has been appointed assistant to the president of the Globe Seamless Steel Tubes Company, Chicago, with headquarters at Chicago.

The Jerome-Edwards Metallic Packing Company, Chicago, Ill., recently removed to its new factory at 3136-3138 W. Chicago avenue, Chicago.

The Independent Pneumatic Tool Company, Chicago, has removed its Detroit, Mich., offices from 736 David Whitney building, to larger quarters at 55 Garfield building.

G. B. Albright, has been appointed manager of the railway department for the western district, of the Lowe Brothers Company, Dayton, Ohio, with headquarters at Chicago.

Daniel Cram Noble, president and treasurer of the Pittsburgh Spring & Steel Company, Pittsburgh, Pa., died at his home in that city on May 8, at the age of 75. He was born in Baldwin, Me., on August 5, 1845, and was educated at Hebron Academy, Maine. For more than 25 years Mr. Noble was identified with branch lines of the Pennsylvania Railroad. He went to Pittsburgh in 1868, and in 1880 became associated with the A. French Spring Company of that city, remaining with that company until 1902, when he founded the Pittsburgh Spring & Steel Company. At the time of his death Mr. Noble was a director of a number of banks and insurance companies of Pittsburgh.

D. C. Noble

George F. Griffin, son of the late Thomas A. Griffin, founder of the Griffin Wheel Company, and a director of that company, died on May 4 at Miami, Fla., at the age of 39 years.

A. B. Burgess, sales manager of the Powell Machine Company, Worcester, Mass., has been appointed eastern representative of the Houghton Elevator & Machine Company, Toledo, Ohio.

On April 30 the New York office of the Sunbeam Electric Company (formerly Schroeder Headlight & Generator Company), Evansville, Ind., was moved from 50 Church street to 52 Vanderbilt avenue, New York.

Frank P. Roesch has been appointed western manager of the Standard Stoker Company, Inc., New York, and has charge of the Chicago office of the company, which was recently opened at 1549 McCormick building, for the purpose of handling the newly developed Du Pont type locomotive stoker. Mr. Roesch was during federal control connected with the United States Railroad Administration as regional fuel supervisor for the Northwestern region and prior to that was employed as master mechanic on the El Paso & Southwestern, the Southern, and the Chicago & Alton. Mr. Roesch is a member of the American Society of Mechanical Engineers and several of the prominent mechanical department associations, and has contributed a number of articles to the columns of the *Railway Mechanical Engineer*.

F. P. Roesch

F. R. Bolles, formerly vice-president and general manager of the Copper Range Railroad, Houghton, Mich., has been appointed vice-president and general manager of the American Automatic Connector Company, Cleveland, Ohio.

J. F. McDonnell, who for the past nine years has been connected with the Dearborn Chemical Company, has been appointed special railroad representative of the packing department, mechanical rubber division of the United States Rubber Company, with headquarters at Chicago.

The officers of the Elvin Mechanical Stoker Company, 23 West Forty-third street, New York, are as follows: Frank H. Clark, president; John R. Given, vice-president; A. G. Elvin, treasurer; Frederick P. Whittaker, secretary; J. Snowden Bell, patent attorney, 149 Broadway, New York.

Carl G. Barth, a pioneer in the machine building industry, has been elected an honorary member of the Taylor Society, New York, which was organized for the promotion of science in management. Since 1899 Mr. Barth has been associated with Frederick W. Taylor at Bethlehem, Pa., conducting experimental work on the fundamental formulas in cutting metals.

J. W. Austin has been elected a member of the Detroit Graphite Company, Detroit, Mich., with the title of assistant secretary. He is well known throughout the paint and varnish industry, having been for 20 years with the Acme White Lead & Color Works, during the past 15 years as general purchasing agent of that company. In addition to other du-

ties in the Detroit Graphite Company, Mr. Austin will direct the purchasing policy for both its Detroit and allied Canadian plants.

The partnership lately existing between L. H. Turner, Jr., and L. W. Garratt, under the name of L. H. Turner, Jr., & Co., dealers in railway equipment, having been terminated by the recent death of Mr. Turner, the business will henceforth be conducted by Mr. Garratt as its sole proprietor, under the name of L. W. Garratt, 358 Union Arcade, Pittsburgh, Pa.

Frank C. Smink, formerly for 17 years president of the Reading Iron Company, Reading, Pa., died on March 3, of a complication of diseases, at his home in Reading, at the

F. C. Smink

age of 74. After an early training with the Philadelphia & Reading Railway Company and in Reading banking circles, Mr. Smink, in 1878, entered the service of the Reading Iron Works, as business manager. He remained in that position until the organization of the Reading Iron Company in 1889, when he was made treasurer, and subsequently served as vice-president and general manager under the presidency of the late George F. Baer, whom

he succeeded in 1902. Mr. Smink was a director of the Reading Trust Company, also the Temple Iron Company, and for many years served as a member of the executive committee and a director of the Pennsylvania Steel Company, the Spanish-American Iron Company, the Maryland Steel Company, the Penn-Mary Coal Company, the Pure Oil Company, and other organizations.

In the issue of March, 1920, an erroneous statement appeared regarding arrangements which the Cincinnati Shaper Company was making for the handling of its foreign business. A representative of the company has gone abroad to demonstrate its machines in various plants on the Continent, but no change is to be made in its present foreign agency connections. The president of the company is P. G. March.

George A. Price has been elected treasurer of the American Arch Company, 30 Church street, New York. Mr. Price started work on the New York Central & Hudson River in the motive power department, at the DeWitt enginehouse, and from there was transferred to the office of the superintendent of motive power of the New York Central. In August, 1912, he resigned to enter the service of the American Arch Company. On March 1, 1918, he was elected assistant secretary, and he has now been elected treasurer. In addition to being treasurer Mr. Price will also continue his duties as assistant secretary.

Fred T. Ley, formerly president of the Napier Saw Works, Inc., Springfield, Mass., is the president of a new company organized to take over the band saw and band saw machine business of the Napier Saw Works, Inc. The new company will be known as the Metal Saw & Machine Company, Inc., Springfield, Mass. Mr. Ley will have associated with him as treasurer and general manager, Henry M. Blanchard. The schedule for the present year calls for a production of several hundred machines and it is anticipated that as many as 2,000 machines will be turned out in 1921.

Peter P. Beck, dealer in railway and manufacturers' supplies, removed his office and showroom on May 1, from 105-107 Chambers street, New York, to 22 Thames street. Mr. Beck is sales agent at New York for the Bettendorf Company, Bettendorf, Iowa; Wine Railway Appliance Company, Toledo, Ohio; Railway Brake Specialties Company, Toledo, Ohio; Slick-Knox Steel Company, Sharon, Pa.; Sturdi-Truck Manufacturing Company, Holyoke, Mass.; Liberty Tool Corporation, Baltimore, Md.; Howe Waste & Packing Company, Providence, R. I.; Wm. A. Tottle & Company, Baltimore, Md.; and the Nu-ex Fire Appliance Company, Columbus, Ohio.

The Victor Saw Works, Springfield, Mass., has been purchased by New York banking interests and new officers elected as follows: President, Winthrop Sargeant, Jr.; vice-president and general manager in charge of operation, George J. Siedler; treasurer, Louis J. Oswale; secretary, William P. Jeffery. W. F. Pollock will remain with the company as assistant manager. The Napier Saw Works, Springfield, Mass., has also been acquired by the same interests, the purchase taking in the hack saw blade business, good will and equipment, but not the plant. The old owners of the Napier works retain the factory and the band saw and band saw machine end of that business.

Harry U. Morton, whose appointment as president and treasurer of the Dunbar Manufacturing Company, Chicago, was announced in the May issue, was born on April 25, 1866,

H. U. Morton

in Painesville, Ohio. He entered railway service in 1891 with the Pullman Company, remaining with that company for 17 years of which he served four years in the manufacturing department and 13 years in the operating department. In 1907 he was appointed vice-president and general manager of the General Railway Supply Company. Seven years later he was appointed vice-president and secretary of the Acme Supply Company, Chicago, the corporate

name of this company being changed in 1917 to the Dunbar Manufacturing Company. On April 1 of this year he was elected president and treasurer of the latter company succeeding Thomas Dunbar, who has resigned.

The Westinghouse Union Battery Company was recently organized in Pittsburgh, Pa., to produce storage batteries for every industry in which batteries are used. The company will specialize in starting and lighting batteries for renewal in automobiles, although the complete line will include batteries for trucks, tractors, motor boats and airplanes; also for home lighting systems, train lighting and railway signals. A. L. Humphrey, president of the Westinghouse Air Brake Company, and active in the management of all of its subsidiary organizations, is chairman of the board of directors of the new company. D. F. Crawford, vice-president and general manager of the Locomotive Stoker Company, is president of the new company, and T. R. Cook, formerly chief engineer and general production manager of the Willard Storage Battery Company, is vice-president and general manager. T. S. Grubbs, vice-president of the Union Switch &

Signal Company, is also vice-president and secretary and treasurer of the new organization.

The Carborundum Company, Niagara Falls, N. Y., is carrying out improvements at a cost of about \$500,000, extending and improving its plant at Niagara Falls and its two furnace plants, one at Niagara Falls, Ont., and the other at Shawinigan Falls, Que. A three-story addition to the paper and cloth plant at Niagara Falls has just been finished; it is 432 ft. long and 81 ft. wide and will provide greater facilities for the storing and curing of all carborundum, Garnet and Aloxite paper and cloth products and for the extension of the rubber bonded wheel department. Another addition, just completed, extends one of the wheel-making and kiln departments, the new building being two stories high, 96 ft. long and 64 ft. wide. Both of these new structures are of concrete and are of the most modern type. Other extensions and improvements have been planned and work will be started immediately. These call for additions to the crushing departments and other improvements at the furnace plant at Niagara Falls, Ont., where the abrasive Aloxite is made, and at Shawinigan Falls, Que., where is located an extensive carborundum furnace plant. Besides these buildings the program calls for the extension of at least 14 different departments at the Niagara Falls, N. Y., plant.

This company has also acquired the plant formerly operated by the Didier-March Company at Perth Amboy, N. J., where it will manufacture a complete line of carborundum refractories. The plant is located on a site of 24 acres and consists of a modern clay working and refractory plant with a capacity of about 100 tons a day, covering a floor space of about 300,000 sq. ft. In addition to this property the Carborundum company has purchased 60 acres of high grade fire clay lands at Bonhamton and a clay excavating plant.

J. J. Thomas, Jr., formerly superintendent of motive power and car equipment of the Mobile & Ohio, at Mobile, Ala., has been appointed district manager of the Oxnard Railroad Service Company, Chicago, with headquarters at Mobile. Mr. Thomas entered railway service in 1881 as a fireman on the Selma, Rome & Dalton, now part of the Southern, later becoming a machinist apprentice on the same road. From 1885 to 1898 he was successively locomotive engineer, machine shop foreman general foreman and master mechanic on the Birmingham & Atlantic. In 1898 he was appointed master mechanic on the Mobile & Ohio, with headquarters at Tuscaloosa, Ala., and was later promoted to assistant superintendent of motive power and car equipment, with headquarters at Mobile. In 1902 he was appointed master mechanic of the Seaboard Air Line, with headquarters at Savannah, Ga., resigning some time later to become master mechanic on the Atlantic Coast Line, with headquarters at South Rocky Mount, N. C. He was appointed superintendent of motive power and car equipment on the Mobile & Ohio in 1909, which position he held until the time of his appointment as district manager for the Oxnard Railroad Service Company.

J. J. Thomas, Jr.

TRADE PUBLICATIONS

TRUCTRACTOR.—The Clark Tructractor Company, Chicago, has issued a pamphlet showing photographs and specifications of all models of the Clark Tructractor, with illustrations showing it at work in various industrial plants.

TOOL STEEL.—A brief discussion of the question whether chemical analyses are of greater importance in the quality of tool steel than its careful manufacture in all processes, is printed in a pamphlet of eight pages published by the Vanadium-Alloys Steel Company, Pittsburgh, Pa.

PNEUMATIC BRAKE EQUIPMENT.—The Westinghouse Air Brake Company, Pittsburgh, Pa., has issued catalogue 2021, which briefly describes and illustrates the standardized UC Westinghouse brake equipment for steam road passenger trains, which, with simple electric attachments, is said to represent the most improved form of electro-pneumatic train brake for both electric and steam road passenger trains.

COWAN TRANSVEYOR.—A booklet of 28 pages, entitled Transveyor Picture Book, is being distributed by the Cowan Truck Company, Holyoke, Mass. It shows by means of illustrations the work that these transveyors are doing in a great variety of industries where they are being used. It also points out the advantages of their construction and contains specifications for all types.

ARCH TUBE CLEANERS.—A revised catalogue of locomotive arch tube cleaners (W-4) has been issued by the Lagonda Manufacturing Company, Springfield, Ohio. The catalogue goes into the subject of arch tube cleaning and describes the different types of standard cleaners made by this company, giving a description of their general construction and usage. It also illustrates repair parts and covers briefly several other products.

INGOT IRON WIRE.—The Page Steel & Wire Company, New York, has published a complete pamphlet describing fully the electrical and physical properties of American ingot iron wire. This is the first complete publication of this data and the result of many tests made during the past two years under the supervision of the Electrical Testing Laboratory, New York, and Frank F. Fowle, consulting electrical engineer for this company.

PORTABLE MACHINE TOOLS.—The Pedrick Tool & Machine Company, Philadelphia, Pa., has issued a comprehensive, well-illustrated catalogue of 96 pages, describing the special machine tools manufactured by the company for use in railway shops, shipyards and general machine shops. Among the tools of special interest to railroad men may be mentioned the portable cylinder boring bar, column boring bar, duplex horizontal boring machine, portable crank pin-turning machine, locomotive pedestal jaw facer and pipe-bending machine.

TANK CAR CENTER SILLS.—The Pennsylvania Tank Car Company, Sharon, Pa., describes its type A-1 center sill in a booklet entitled "One Reason Why Pennsylvania Tank Cars Are Used by Leaders of Industry." Although the booklet briefly describes the construction of the sill, it deals principally with tests conducted by Professor Endsley of the University of Pittsburgh at the testing laboratory of the Union Draft Gear Company in December, 1918, to determine the relative strength of the type A-1 center sill, which is patented and used exclusively by the Pennsylvania Tank Car Company, and the type A center sill, now in general use. The booklet contains a number of illustrations.

A good deal more could be said in favor of modernizing engine terminals than will be found in the article on Modern

Preparedness in Engine Terminals

Versus Obsolete Engine Terminals appearing in this issue. The difficulty of operating an out-of-date engine terminal where only heavy locomotives are handled makes it a tremendous task to

keep the power moving through the terminal, and the effect on the morale of shop employees that would be obtained through improving these facilities would in itself justify a considerable expenditure towards improvement.

Engine terminals might be styled the front line trenches. Without proper facilities, the day on which the power will break through these front line trenches and the locomotives descend upon the back shop will inevitably be advanced. If these terminals have modern roundhouses with adequate machine shop equipment, boiler washing plants and efficient coal and ash handling layouts, the equipment will certainly be kept in action for a much longer period, and when the break comes it will be an orderly retreat that will not tax the resources of the back shop to the limit. This simple analogy between the terminal and the trenches should be taken to heart by those who are interested in having our railroads make good.

Engine terminals should not only be modernized, but must be kept up to date. The strain on any terminal increases even more rapidly than the capacity of motive power handled, and since we must look for further increases in this direction, preparedness in engine terminals requires that these terminals be built for the future, and that there be room for additional buildings when these are needed. How often has it been necessary to change the location of an entire terminal in order to get the needed space for additional structures? It is not safe to assume that locomotives

have attained their maximum capacity and that economy devices have reached the limit. It has been stated that the steel industry must double its capacity every ten years to keep abreast of this country's requirements. How long can you meet the growing requirements of your railroad with congested, poorly planned and inadequately equipped engine terminals; what is it costing your company to handle locomotives with antiquated facilities?

Several times recently, reference has been made in the columns of the *Railway Mechanical Engineer* to the possibilities of economy by grinding

A. R. A. (Section III) Discusses Car Wheel Grinding

by the animated discussion of car wheel grinding which followed the presentation of the report of the Committee on Car Wheels at the recent convention of the American Railroad Association, Section III, at Atlantic City. C. T. Ripley, general mechanical inspector of the Atchison, Topeka & Santa Fe, called attention to the practice of reclaiming slid flat cast iron car wheels by grinding. He stated that the work has been going on for approximately ten years on the Santa Fe with important savings; no objections to the practice had developed. Cars ride smoother, there is less wear and tear on equipment and once a wheel is ground smooth, round and concentric with the journal, there is less tendency for it to slide again.

The question was raised by C. E. Fuller, superintendent of motive power of the Union Pacific, as to the depth of chill in cast iron wheels and whether there was danger of grinding through it. The consensus of opinion was that no danger of grinding through the chill existed, since it was at

least $\frac{1}{2}$ in. thick; and if the chill was almost worn through, the wheel would have to be scrapped, anyway, for flange wear. Some of the members considered it dangerous practice to grind out flat spots, due to the punishment the wheel had received in sliding and the consequent danger of the wheel bursting. The answer to this argument was that badly brake burned wheels were not reground and that those with small checks were not appreciably weakened.

It developed that before the war the cost of grinding car wheels on the Santa Fe was \$.53 per pair, including all overhead, interest and depreciation charges. Mr. Ripley stated that the cost is now around \$1.00 per pair. In this connection, it is interesting to note that the estimated cost given in a car wheel grinding article on page 355 of the June issue of the *Railway Mechanical Engineer* is \$1.50 per pair. Even this estimate of cost allows a total saving of \$6.05 per pair, which is large enough to warrant the installation of a car wheel grinding machine in any shop where enough slid flat wheels are received to keep the machine busy a fair proportion of the time.

Discussion of the report also developed the fact that some roads take light truing cuts on steel wheels to remove any eccentricities in the wheels themselves or due to mounting. New chilled cast iron wheels are being ground by a large eastern road to accomplish this purpose and it seems probable that, where only a light cut is to be taken, a grinding machine will perform the operation more quickly and with less waste of material than a lathe. Certainly the ability to remove steel by grinding need not to be questioned, since powerful car wheel grinding machines are now used by manufacturers to grind the tough manganese treads of steel car wheels. The importance of the subject would seem to justify especial consideration by the Committee on Car Wheels to determine what limitations there are to car wheel grinding and to adopt recommended practices for the guidance of the roads.

One of the most difficult problems with which the mechanical department has to contend is that of inadequate power plant capacity. The stationary boiler plant upon which the shop or roundhouse is dependent is one of the most vital spots on the railroad and unquestionably there are a very large number of outgrown, overburdened boiler installations in operation on the railroads today. The problem of increasing the efficiency and capacity of these boilers is an important and difficult one in view of the cost of installing additional boilers, which involves additional space, added foundations and setting, new boiler room construction and, finally, the boiler itself. One way in which this situation can often be improved without involving all the expense incident to the installation of new boilers is to increase the efficiency and capacity of the stationary boilers that are now in service. With all that has been said recently in favor of modernizing locomotives it is surprising that the opportunity for modernizing stationary boilers has not been given more general attention. The application of the superheater to stationary boilers would seem to offer advantages comparable with the results obtained in locomotive service. A good exposition of the improvement that can be effected through modernizing stationary boilers in railroad service will be found in an article contributed to this issue by the assistant engineer of an eastern railroad. The advantage of having ample steam pressure for the generator sets, plenty of air for the shops and good dry steam for the steam hammer is obvious; the problem is to secure the desired results with the means available. Modernizing your stationary boilers may prove a practical means.

Modernized Stationary Boilers

The average roof is one of the details about a freight car that leaves much to be desired, though there are undoubtedly many specific instances of roofs that are giving eminently satisfactory service. The suggestion that the car roof is still in the process of evolution and the prediction that the ultimate roof

Evolution of the Car Roof

will be rigid and of all-steel construction, comprising $\frac{1}{8}$ -in. sheets or heavier, is interesting. This suggestion and the prophecy come from a representative of the car department of the largest Canadian railroad, who is the author of a very comprehensive review of the development of the car roof recently presented before the Canadian Railway Club and abstracted in another column of this issue. The information that shingles were employed in early car roof construction is interesting in the light of subsequent developments in car roofs, as outlined in the article referred to. Not only the development, but the motive behind this development and the obstacles that have been encountered and that confront roof construction today, are plainly stated in this article. It is clearly the duty of the car department to give the car roof more attention. As is pointed out, the position of the car roof in relation to other parts of the car does not easily lend itself to proper maintenance. Other parts are constantly being inspected for defects, but roof failure is seldom observed until the damage has actually occurred. As in the famous shingling episode, the need for roof maintenance in fair weather is not apparent and in wet weather it is too late to be attended to.

There is a growing belief that autogenous welding has its limitations. The early enthusiasm with which the process was accepted by the railroads is suffering a reaction which, no doubt, is the natural outcome of the attempt to make it a panacea for all the ills of wear or failure to which metal parts of railway equipment are heirs. There is, however, grave danger that the reaction will carry the railroads as much too far in the direction of conservatism as the early enthusiasm carried them beyond the limits of safety and economy, considering the undeveloped state of the art when it was first brought into the railroad field.

The Status of Autogenous Welding

There are three prime essentials to successful autogenous welding. The first is a properly trained and experienced operator; the second is the proper preparation and laying out of the work; the third is the use of proper welding materials and appliances. The third requirement involves no real difficulty, as proper materials and appliances are available. But in the case of the first two essentials much remains to be done before the full possibilities of the art can be realized. The danger from the standpoint of future development lies not in the establishment of temporary limitations, but in failure to recognize the true nature of the cause which makes them necessary. Machinists, boilermakers, and even barbers, after a few days of special training, are alike frequently considered competent to operate on important work. When the results are not all that should be expected from really competent operators, there seems to be a tendency to attribute the failure of inherent limitations of the process itself. The fact is overlooked that success in welding depends far more on the skill and the integrity of the operator than in the case of any of the well established trades, and yet years of apprenticeship are required in these trades.

This is in no sense an argument against the establishment of such temporary limitations as are best suited to guard against danger from ill advised and incorrect applications of the process. But unless the nature of the real problem is clearly recognized the minds of many mechanical department officers will be closed to future developments and

limitations, once established, will be considered as permanent.

A few railroads have attacked with energy and thoroughness the economic and technical problems involved in the establishment of intelligent limits and correct practice in the application of autogenous welding. These roads have met with success in fields where the average experience has been failure and their success is justification for the belief that future developments will undoubtedly make possible a considerable extension of the present limitations. The art is in its infancy and its possibilities for the conservation of both labor and material are so great that it would be extremely unfortunate for the railroads if a misapprehension as to the nature of its present limitations were to delay the day when they may legitimately be extended.

For many kinds of work performed on lathes, especially turret lathes, boring mills and other chucking machines, there is a possibility of greatly increased production by the use of air operated chucks. This is particularly true when an order is put through in which machine operations require the chucking of a large number of duplicate parts. The time required for chucking is reduced many times over by the use of air operated chucks and at the same time the work is held so much more rigidly that it is possible to take heavier cuts and reduce materially the time required for the operations. In mechanical construction, several modern designs of air operated chucks have passed through a sufficiently long and rigorous test period to show up any weak points and objectionable features. Difficulty with the jaw operating mechanism has been largely overcome by the use of special heat treated steel levers and hardened alloy steel pivots. With hardened and ground ways in the chuck jaw slides and draw tubes, both wear and friction have been reduced to a minimum and the proper proportion of operating arms has given ample holding power. The air cylinders have presented another structural weakness, air leakage where the air enters the cylinders, especially on fast running machines, making frequent repacking and adjustment necessary. By finally providing a durable packing to overcome this difficulty and in addition making the chucks economical in air consumption, dust proof and adaptable to any ordinary type of turning machine, air operated chucks are due to come into much more common use in railway machine shops, with a corresponding increase in machine shop output.

In the January issue of the *Railway Mechanical Engineer* there was published an analysis of the railroad situation which showed a very serious shortage of facilities. During the past six months no progress has been made in reducing this shortage and the normal capacity of the railroads is at present not great enough to meet the demands of the traffic. Strikes have interfered with operation and freight has accumulated. So it happens that although the railroads are now handling more traffic than ever before, the situation is very critical. There is danger of fuel shortage in certain sections of the country; industries are not operating at full capacity and shutdowns and serious industrial depressions are threatened unless raw materials and finished products can be handled more rapidly.

A great responsibility rests on the mechanical department in this crisis. Anything short of the highest possible efficiency in transportation during the next six or eight months will be a calamity and it is the duty of every man concerned to see that the roads move as much freight as possi-

ble. There are various ways in which this can be accomplished. The first is by seeing that every employee realizes the seriousness of the situation and does his utmost by staying on the job and by doing efficient work. The eight-hour day has reduced the capacity of the shops; they cannot be enlarged to meet the present situation; therefore it is essential that there shall be no slackers.

The equipment situation is so serious that it has become a national question. Locomotives and cars must be utilized to full capacity to handle the nation's business. The percentage of locomotives needing classified repairs is not unusually high, but many engines are held out of service because minor repairs are not made promptly. For this reason roundhouse work should receive special attention. The bad order car figures show room for improvement; 180,000 cars, or 7.4 per cent of the freight equipment is in bad order and many cars shown as serviceable are fit only for rough freight or light loading. It may be a difficult task to improve conditions under the present circumstances, but the mechanical department should tackle the job with might and main, realizing that it can perform a great service for the country. If additions to the facilities will speed up the work, every effort should be made to install them. If changes in design will reduce maintenance troubles they should be made. Finally, if the railroad shops cannot handle the work, assistance should be secured from contract shops. The situation demands energetic action and nothing should be left undone that will speed up repairs to the equipment.

NEW BOOKS

Car Design. By L. W. Wallace, M.E. 35 pages, 6 in. by 9 in., illustrated, bound in stiff paper. Copies obtainable from H. Rubenkoenig, assistant professor of railway mechanical engineering, Purdue University, Lafayette, Ind.

This is the second edition of these notes and has been brought up to date to include recently adopted M. C. B. standards and recommended practices. The work does not exhaustively treat the subject, but deals only with such portions of the car as are usually given theoretical consideration by the car designer. It is only intended to meet the needs of classroom work, and is especially valuable to those technical schools giving railway mechanical engineering courses which include car design. The practical car designer may also derive some benefit from the work.

Woods Westinghouse E-T Air Brake Instruction Pocket Book. 258 pages, 5 in. by 6½ in., 55 illustrations, bound in cloth. Published by the Norman W. Henley Publishing Company, 2 West Forty-fifth street, New York.

Any book on air brake equipment must be strictly up to date to be of value, particularly if the book relates to the E-T type, which has undergone very rapid development to meet the ever-increasing demands upon locomotive brake equipment. This book, which has just come off the press, not only contains a full description of the E-T 6, which is the most recent type placed on locomotives, but is a very complete text on the design and operation of the entire E-T equipment and accessory apparatus. The text is admirably illustrated with cuts of the various parts of this apparatus and diagrammatic views showing each zone of air pressure in a distinctive color. This book should be of great assistance to locomotive engineers and others interested in the operation of the E-T brake equipment who are so located that they cannot take advantage of the lectures and demonstration afforded in an air brake instruction car and it should also be of value to traveling engineers, air brake inspectors and instructors not only for the information contained in the volume, but for the reason that these colored diagrams afford a very simple and effective method for instructing others in the workings of this intricate apparatus.

COMMUNICATIONS

MORE LIGHT ON THE SERVICE OF SUPPLY

WEST SPRINGFIELD, MASS.

TO THE EDITOR:

In the June issue of the *Railway Mechanical Engineer*, under "Communications," is an article signed by General Purchasing Agent on Service of Supply. I am sure every railroad engine house or repair shop man will be interested in this General Purchasing Agent's views, for they express in a few words a full explanation of why the supply parts come to shop late and in about half requirement lots.

A man in the shop cannot devote all his time to repairing engines because the stores department fails to provide the materials required in his shop work. The shop forces must stop progressive operations and spend valuable time looking and planning to get past and deliver a locomotive when an important or perhaps only a trivial item of material is missing. It costs 72 cents per hour to have mechanics searching for parts and \$2.00 per hour to hold a locomotive out of service.

My work as an engineer in charge of shop production and scheduling of the work in a locomotive repair shop has placed me in a position where definite values are known, and exactly what the factors are which tend to hold up our shop output. I know beyond a doubt that there is no one factor of distress in all our shop list that is costing more in actual cold cash through lowering of shop output and as a cause for continuing defective parts in service than the lack of an adequate supply of materials. This is our worst shop problem today.

If our General Purchasing Agent could spend one day each month alone among the shop and engine house foremen, learn to know the gang leaders and their troubles, he would not make any such slip as he did by saying "No such thing as work held for material." *Work is delayed every day because of lack of material.*

Men of vision and business determination create their credits as they advance, and see to it that subsequent events produce the requisite profit to meet their obligations. Credit is established and maintained by meeting every business obligation promptly and squarely. Where would any of our large roads have been today had they hesitated to advance because of credits? Harriman, Hill, and others advanced and their credits expanded to meet their requirements.

Suppose, for example, we require three 1¼-inch pipe unions to complete a locomotive out of shop and into service. The store room only received one because the 30 per cent credit after being distributed only purchased one. This locomotive must go into service, and there are, we assume, only two pipe unions, a matter of \$1.00 between it and earning \$75.00 per day. Our piper spends perhaps an hour searching scrap for old ones; perhaps finds a poor one that may just about half-way hold, or long enough to get out of shop and give the engine house trouble later. This hour's time of piper and helper places this union at a cost of 72 cents + 49 cents, or \$1.21. But we are still short one, and the only thing to do is to rob from any locomotive in the shop or from some shop heating pipe. A chance of losing \$75.00 per day in service earnings forces anything so long as we obtain the required fitting. Later we will have to replace it by robbing another and the labor charge will average \$2.00 each for these fittings.

The vital point is we pay for all our material, even though we have to hide half the cost in labor charge. Give us new material at a less cost to the company and place the cost where it belongs, on the purchasing agent's books, and not on shop pay-roll. The increased saving in the direct purchase will sustain the credit advanced, not to mention the intangible

effect in dollars resulting from encouraging the shop men.

Who ever heard of a general purchasing agent crying himself to sleep because a wrecking crane cost \$25,000, and perhaps stands 12 months and never is used and passing into an obsolete class every day? Or we must scrap it and purchase a larger one to stand around on the siding, tying up a larger sum and losing more interest. The fact is, when we require this crane we want it at once, and very urgently, and in a few minutes' time it liquidates all this interest and depreciation charge. It is not too much in large wrecks to say a crane may save its entire cost on one job. The same thing applies to material stocks; we should not stock carelessly but wisely, and do it as a feature of good business management. Do not state "The road in possession of the largest stock of live stores is the poorest managed."

You do not cut down on coal because of depleted credits. You spend \$2,500 on a locomotive to apply superheat and save coal. Here you advance credit and sustain it on the saving in coal. Nothing strange about it, just good hard-headed, plain business sense.

FRANK ROBERTS.

PIECEWORK NEEDED TO INCREASE PRODUCTION

ROSELLE PARK, N. J.

TO THE EDITOR:

I read with much interest the letter printed in the May issue of the *Railway Mechanical Engineer* entitled *The Mechanic's Viewpoint*. However, I wish to disagree with the author on one point in particular, namely his opposition to piecework and his reasons therefor.

I claim that the time has arrived to again install the piecework system in railroad shops in order to increase efficiency and production, which have fallen during the last two years. It is a well-known fact that a good deal of this reduction in output was due to the abolition of the piecework system. To pay men according to their occupation on a flat base is unjust to the good worker and the poor worker. The one is underpaid and the other overpaid. The workman working at an efficiency of 90 per cent should receive more pay than the one working at 80, 70 or less per cent. This should be done by a proper piecework or bonus system. There must always be an incentive for mechanics to increase production and where this incentive is lacking the best workmen will fall to the level of the average and the supervising forces will have to devote a good deal of their time to keeping the slackers on the job. Your correspondent thinks "indifferent quality" is unavoidable under the piecework system. I don't think so; in fact the contrary is nearer to the truth. With a live piecework inspector on the job and the supervising forces not sleeping it is easier to obtain good workmanship under the piecework system than when working at the day rate. Under the piecework system employees can be held to strict accountability for performing inferior or indifferent work. In some cases where carelessness or neglect is shown they can be disciplined by making them do their work over again without extra pay. This usually acts as a sure cure against carelessness.

As far as the nerves of the nation are concerned, I don't think this should worry us if we approach the subject with a fair mind and spirit. Piecework or bonus prices should be set according to the output of an average good mechanic.

The high cost of living today is due to a large extent to under-production of the American workman. Less is being produced per day per man than formerly and more is being demanded. The logical thing to do then is to produce more, and since a proper piecework or bonus system will work along such lines it should be installed again in railroad shops for the benefit of the faithful railroad mechanics and helpers, the owners of the railroads and the public.

FRANK J. BORFR.

LOCOMOTIVE FEED WATER HEATING*

Development and Possibilities Outlined with Particular Reference Made to the Open Type of Heater

BY THOMAS C. McBRIDE

THE use of feedwater heaters on locomotives dates back to the beginning of the locomotive itself. There are records of the application of an "open" or "injection" type heater to a locomotive in England in 1827, and an English patent of 1828 describes a tubular heater for the same purpose. Ross Winans of Baltimore applied tubular heaters to two types of Baltimore & Ohio railroad locomotives in 1836. It is worthy of note that the desirability of the feedwater heater for the locomotive was recognized at these early dates, although it must be appreciated that the advantages possible at that time were proportionately greater than at the present time because of the low-steam pressure then in use.

Every conceivable type of heater and all possible sources of heat, even the hot ashes, seem to have been proposed or tried,

or, of the closed or surface type in which the heat from the condensation of the exhaust steam passes to the feedwater through thin sheets of metal, generally in the form of thin brass tubes. Practically all of the development work to date that has been at all successful has considered only the surface type. There are a great many heaters of this type in service in Europe, but there are objections to it for locomotive use. It is a complex and delicate structure; it also wastes the water condensed from the exhaust steam with its heat or raises complications as to saving it, and it requires enough exhaust steam to heat all of the feedwater. On the other hand, the open or injection type of heater necessarily recovers both the water condensed from the exhaust steam and its heat so that both are returned direct to the boiler with the water taken from the tender. Less water is therefore taken from the tender and less exhaust steam is required for the heating.

The McBride Feedwater Heater

The adoption of an open heater for the locomotive may seem a radical step, but the author has devised an open type of feedwater heater which is being manufactured by The Worthington Pump and Machinery Corporation and is fully described in the *Railway Age* of Sept. 5, 1919, in which no new elements are used. The heater itself is of a general type that has been in use in marine service for at least twenty years.

Fig. 1—Curves Showing Estimated Coal Saving with Feed Water Heater

and in view of the amount of study that has been given to the subject it seems rather remarkable that locomotive feedwater heating is not now in more general use. Possibly the reason lies in the fact that it is only in comparatively recent years that the essentials of heater performance and pump operation have been understood. Furthermore the small size of the locomotives formerly in general use limited the saving per locomotive, and the general adoption of the injector, because of its simplicity and convenience, rendered feedwater heating impossible, for injectors heat the water which they use to such an extent by live steam that there is little or no opportunity for further heating.

There are two possible sources in a locomotive from which otherwise waste heat may be obtained to heat the feedwater: (a) the waste gases in the smokebox or stack, (b) the exhaust steam. Stationary practice with economizers indicates that waste-gas heaters cannot be supplied with cold water because the accumulation of condensation and soot on them seriously interferes with their efficiency. It is, therefore, necessary to turn to the exhaust steam for the source of heat and to develop this type of heater first, leaving the waste-gas heater for later development as may be found either necessary or advisable.

The exhaust-steam heater may be either of the open or injection type in which the exhaust steam comes into direct contact with the cold feedwater so that the water condensed from this exhaust steam is added to and mixed with this feedwater;

Fig. 2—Curves Showing Coal Saving Based on Test Plant Results

The open heater with the oil separator to remove the oil from the exhaust steam before it enters the heater because of its merits has been almost universally adopted for stationary plants. One of these heater and pump units was thoroughly tested out on the locomotive test plant of the Pennsylvania Railroad at Altoona, Pa., in 1917, and has been in operation on road service since October, 1918. Three more units have been in operation for approximately a year on pooled locomotives and have given no trouble other than the usual pump maintenance. Nothing has developed indicating that the open heater as a type is not well adapted to the locomotive and the coal and water savings have been so marked as to be evident to the crew.

The pump is much easier to operate than an injector, as it

*From a paper presented at the spring meeting, St. Louis, Mo., May, 1920, of the American Society of Mechanical Engineers.

requires only a slight turn of the 1-in. throttle valve to either start it or to make it run faster or slower as the boiler may need more or less water. It does not require priming and can be operated continuously at low capacities where the injector must be stopped and started periodically. The feed pump should not be used, as is often done with the injector, to fill the boiler on the down grade and then be shut off as long as possible on the up grade; first, because there is not as much inducement or necessity for operating it in this way and, secondly, because the prime purpose of the heater is to recover heat and it can only do so when the locomotive is pulling and exhaust steam is available for the heating. If the injector is operated continuously and maintains a constant water level in the boiler each pound of steam generated will require 1,276 B.t.u. from the fire with 200 lb. steam pressure, 150 deg. superheat, and 40 deg. water in the tender. If the injector is shut off each pound of steam will require somewhat more than 925 B.t.u. so that the amount of steam from the same fire will be increased less than 38 per cent. It will later be shown that under the same conditions the feedwater heater would increase the amount of steam about 13.6 per cent. The feedwater heater will, therefore, materially increase the amount of steam on the up grade, although not to the extent possible in the case of the injector, and should be depended upon to feed the boiler entirely on the up grade with the consequent greater amount of heat recovered from the exhaust and more nearly constant water level in the boiler.

Advantages of Locomotive Feedwater Heating

It is not possible to make an exact general statement of the advantages to be obtained from locomotive feedwater heating, because much depends on the particular locomotive to which the heater is to be attached, the capacity at which it is worked, the temperature of the water in the tender, and the basis on which the advantages obtained are stated. We are liable to base our notions as to the advantages of feedwater heating on the results obtained in stationary practice where the coal saving is very properly considered as equivalent to the reduction in the amount of heat necessary to evaporate the water because of the higher temperature at which the water is delivered to the boiler. In the case of the locomotive, however, with its very complicated relations of the different operations that are going on, and the very wide range of capacity through which the boiler is operated, there is generally a much greater coal saving than in stationary practice. Three factors enter into the final result: 1, the reduction in the amount of heat required to evaporate the water in the boiler, which might be called the *heat saving due to the feedwater heater*. 2. The reduction in the amount of heat required results in a greater reduction in the amount of coal required because of the better efficiency of the boiler at the lower rate of combustion. These two factors give the *coal saving based on water evaporated*. 3. The exhaust steam taken by the heater from the exhaust ports of the locomotive reduces slightly the back pressure in the locomotive and should show some advantage. All three factors combined will give the *coal saving based on indicated horsepower*.

Heat Saving Due to Feedwater Heater

The first factor, the heat saving, is determined by the amount the feedwater is heated by exhaust steam taken from the locomotive. This factor will evidently be greatest when the tender-water temperature is low and when the exhaust steam pressure in the heater is highest, as this pressure determines the temperature to which the feedwater can be heated. This pressure will be highest when the locomotive is working hard, and when the exhaust steam for the heater is taken from that part of the steam valve chests or cylinder saddles where its pressure is greatest. The exhaust steam from the feed pump need not be wasted, since it can be and is used in the feedwater heater, but this use prevents the recovery of the

same amount of exhaust steam and heat from the exhaust of the locomotive. The amount of steam used by the feed pump is, therefore, a direct charge against the saving due to feedwater heating as compared to injector operation when considered in the light of recovery of waste heat from the locomotive exhaust, or when estimated by the temperature rise of the feedwater in the heater.

The tabulation given in Table 1 is based on heating the feedwater to 215 deg. This is quite conservative, as it has been found easily possible to obtain this temperature with the open type heater referred to even with tender-water temperatures of 40 deg. and on locomotives worked at less than two-thirds of their maximum steaming capacity. The tabu-

Fig. 3—Analysis of Coal Saving Resulting from Feed Water Heating

lation shows that greater heat saving is possible with saturated than with superheated steam locomotives; therefore the percentage of coal saving will be greater with saturated than with

TABLE 1—HEAT SAVING DUE TO FEEDWATER HEATER

Assumed steam pressure in branch pipe, lb per sq. in.	200	200	200	200
Assumed superheat, deg. Fahr.	None	None	150	150
Assumed temperature water in tender, deg. Fahr.	40	70	40	70

Heat required, per cent.	87.0	89.25	87.81	89.95
Heat saving as compared to injector operation, per cent.	13.0	10.75	12.2	10.05

superheated steam locomotives. Table 2 gives the exhaust steam required for the heating. The percentage of water saved is shown by Table 3.

The allowances which have been made for the steam used by the feed pump are based on carefully conducted tests of the feed pump and heater, which show that this feed pump when running with saturated and fairly wet steam required for its

operation 2 per cent or less of the weight of steam generated by the boiler. The feed pump, therefore, uses 2 per cent or less of the heat required from the fire by the saturated steam locomotive, but in the case of superheated steam locomotive the feed pump will require but about 1.75 per cent of the heat from the fire of the locomotive because of the greater heat required to generate the superheated steam. The tabulation is based on steam leaving the branch pipe at 200 lb. pressure

TABLE 2—EXHAUST STEAM REQUIRED FOR HEATING

Assume tender water temperature, deg. Fahr.....	40	70
B.t.u. required to heat one pound of feedwater to 215 deg.:		
From 40 deg.....	175	145

Water saving, per cent.....	16.4	13.3

parison to injector operation, it is not possible to apply the usual short rule customary in stationary practice stating that a certain number of degrees of heating of the feedwater results in 1 per cent heat saving, but rather that it is more exact to state, assuming the conditions of the table, that in the saturated steam locomotive, after the first 23.8 or 23.2 deg. heating, each 11.9 or 11.6 deg. of heating represents 1 per cent heat saving, and that in the superheated steam locomotive after the first 22.3 or 21.8 deg. of heating each 12.8 or 12.5 deg. of heating represents 1 per cent heat saving, the first figures in each case applying with 40 deg. and the second figures with 70 deg. water temperature.

The locomotive with the open heater or the surface heater saving the water condensed from the exhaust steam requires the extra 2 per cent steam to operate the feed pump, but from 15 to 18 per cent of this 102 per cent is recovered, so that the net water saving is from 13.3 to 16.4 per cent respectively for the assumed summer and winter conditions as compared to injector operation.

Coal Saving Based on Water Evaporated

In order to obtain the coal saving based on water evaporated it is necessary to consider particular locomotives, since this factor involves the change in the efficiency of the boiler with varying boiler capacity. For this purpose the curves of Fig. 1 have been prepared. The curves on the left marked A are on the basis of 10 per cent heat saving; those on the right marked B on the basis of 12 per cent heat saving. The upper solid curves marked "injector" are test plant results of a consolidation, atlantic, and mikado type locomotive respectively and show the total amount of water evaporated per hour

against dry coal fired. The dotted curves marked "heater" for each of these three locomotives show the amount of water that would have been evaporated by the same amount of coal with a feedwater heater reducing by 10 per cent and 12 per cent respectively the amount of heat required to evaporate the water and superheat the steam. The vertical distances between the solid and dotted curves represent the amount of coal saved and these quantities are shown in the lower set of curves. This lower set of curves, therefore, shows the coal saving based on water evaporated due to the feedwater heater that follows a reduction of 10 per cent and 12 per cent respectively in the amount of heat necessary to evaporate the water and superheat the steam. These curves show that the feedwater heater attached to a locomotive will effect a coal saving beginning at low capacities practically identical with the heat saving, or the coal saving which we have been accustomed to in stationary practice, but which increases at first gradually and then more rapidly as the capacity of the locomotive is increased, reaching values twice or more than twice these figures as the maximum capacity of the locomotive is approached. It would be difficult to credit this result were it not warranted theoretically by the second factor mentioned above, and had it not been confirmed in test plant results with a wide margin to spare. A study of the upper curves in connection with the lower curves with both figures will show that the very great coal saving possible is accompanied by an increase in steaming capacity due to the feedwater heater and that it should be possible to work the locomotive with the heater at greater steaming capacities than are possible with the injector, but how much greater would depend largely on the particular locomotive.

Coal Saving Based on Indicated Horsepower

Saturated steam locomotives should show a further gain of a few per cent from reduced back pressure. Test plant records show some reduction in this back pressure in super-

TABLE 4—HEAT RECOVERED BY THE FEEDWATER HEATER

this paper. Table 4 shows the heat recovered by the feedwater heater and Table 5 the coal saving and increase in efficiency. They show a coal saving curve of the same general

character, but slightly higher than the curve for the mikado locomotive of Fig. 1, based on water evaporated, although the tests were made under practically identical operating conditions as to temperatures and pressures.

Exhaust Steam Available for the Draft

The question has been raised as to whether the exhaust steam taken from the locomotive by the feedwater heater would cause trouble with the draft. This question could be analyzed from the partly theoretical curves of Fig. 1, but as actual operating conditions are of more interest, curves have been added to Fig. 3 showing the total exhaust steam taken by the heater and the exhaust steam taken from the exhaust ports of the locomotive. The distance between these two curves represents the exhaust steam furnished by the feed pump to the heater. It is noted that the curve of exhaust steam taken from the exhaust port is below the curve of coal saving. The feedwater heater, therefore, reduced the amount of coal burned at a greater rate than it reduced the amount of exhaust steam, so that there was a surplus of exhaust steam left available for the draft, no necessity for reducing the size of the blast nozzle and consequent possibility of reduced back pressure in the locomotive cylinders because of this heater. For instance, at 2000 i.h.p., the reduction in the amount of coal burned was 18 per cent, and in the amount of exhaust steam, $12\frac{1}{2}$ per cent. As compared to injector operation, 82 parts of coal had to be burned and $87\frac{1}{2}$ parts of exhaust steam were left available for the draft to burn it.

Conclusions

Viewed from the standpoint of coal and water saving, the adoption of the heater becomes a question of interest on first cost, depreciation and maintenance cost against these savings. Viewed from the standpoint of increased capacity, the question becomes one as to whether the feedwater heater does not offer increased capacity at the lowest first cost, especially if, as in the case of the comparison of the consolidation locomotive with and the mikado locomotive without a heater, the adoption of the heater permits of the use of a simpler and less costly type of locomotive. The feedwater heater offers a solution of the pressing problem of these times, when so many fairly old and small locomotives have outgrown their usefulness because they are not large enough for present-day demands. The feedwater heater will not only increase the capacity of these locomotives, or what might be called their economical operating capacity, at a comparatively low cost and with little change in them, but it will also show a larger percentage of coal saving because of their full loading than would be obtained with present-day larger locomotives. The feedwater heater offers the peculiar advantage of being of most assistance to the locomotive just at the time when the locomotive needs assistance. It offers its greatest saving in fuel or increase in capacity in the winter time, and these advantages are not effected by reduced steam pressure or superheat, but continue in spite of them and at a proportionately greater rate.

THERE WAS A MAN in our shop, he was so wondrous wise; he wouldn't wear his goggles—now he has no eyes—*Fred Meyers.*

METHOD OF KEEPING COMPRESSOR VALVES CLEAN.—Air compressor valves in a certain plant, after a few days' run, would cake with dirt and rust and show signs of corrosion. The explanation offered was that carbonic acid formed by the carbon dioxide and moisture of the air attacked the valves and caused the trouble. It was suggested that a weak alkali such as a soap solution would be sufficient to neutralize the acid and prevent the trouble. One quarter pint of soapy water was fed to the low pressure lubricator three times a day, and since that time the valves have remained clean and have a mirror-like polish.—*The Atlantic Lubricator.*

SPECIAL LOCOMOTIVE DEVICES ON THE ANN ARBOR

In March, 1919, two 11-in. air compressors were applied to a locomotive on the Ann Arbor Railroad, the piston rods to these pumps being drilled and equipped with special means for the lubrication of the air cylinders as shown in Fig. 1. The special features involved in this means of lu-

Fig. 1—Arrangement for Lubricating Air Cylinders

brication were designed by J. E. Osmer, superintendent of motive power of the Ann Arbor, and application for patents covering the novel features of the device has been filed.

The air intakes consisted of pipes leading down at an

Fig. 2—Combination Valve for Distributing Superheated Steam

angle of about 20 inches from the air cylinder, and on the lower end of the pipe Westinghouse air strainers were applied, thereby preventing any oil getting to the air cylinders from any other source than through these piston rods. On

the downward stroke with steam pressure exerted to the top side of the piston, pressure is also exerted above the oil and water collected in passages holding ball *D* down to its seat. On the upward stroke and if the piston in the air cylinder has traveled one inch, enough pressure has been accumulated to raise ball *D* off the lower seat and force it against the upper seat, thereby permitting the oil and water collected in cavity *C* to pass into and against the cylinder walls.

It is stated that since the application of this arrangement to the air pumps, no indication of groaning has been experienced, and the air passages and the air discharge pipes are absolutely free from carbon. These pumps have run one year between the shoppings of this locomotive, and when the pumps were dismantled it was found that there were no indications of scoring. The same air valves and seats were put back into the pumps and the same pumps are now in service giving satisfactory results.

At the time this installation was made, an automatic valve was also installed as shown in Fig. 2, the duty of which was to furnish superheat steam to the steam end of the air pumps at all times when the throttle of the locomotive might be

open, and since the date of its application over a year ago, an increase in speed of the pumps has been noticed with the use of superheated steam over the use of saturated steam when the main throttle is closed and a considerable fuel saving has been observed. This same arrangement also has a special field in connection with the operation of locomotive stokers, coal pushers, and other devices.

Superheat steam from the superheater header on the steam pipe is connected at *A*. The usual steam pipe from the boiler head ordinarily connected to the air pump, steam heat stoker, etc., may be connected at *B*. *C* is the steam delivery pipe to air pumps, steam heat pipes, etc. *D* may be used as a connection to furnish steam to the electric generator. When the differential piston moves to the left, the rounded end of the piston rod seats against a copper gasket, making the joint absolutely steam tight. At the end of the smaller portion of the differential piston, this being cast iron against cast iron, no wire drawing of steam is noticeable due to the fact that in the passage *B* and in the conducting passage to *C*, pressure being practically balanced, eliminates any wire drawing.

RAILWAY FUEL ASSOCIATION PROCEEDINGS

Reports and Papers on Feed Water Heaters and Possibilities of Lignite and Carbonized Coals

THE twelfth annual meeting of the International Railway Fuel Association was held at the Hotel Sherman, Chicago, May 24 to 26 inclusive, with H. B. McFarland, engineer of tests, Atchison, Topeka & Santa Fe, presiding. The convention was opened with an invocation by Dr. Frank Gunsaulus, president of Armour Institute of Technology, followed by an address by Roy V. Wright, editor of the *Railway Mechanical Engineer*.

Mr. Wright's Address

The International Railway Fuel Association can well be proud of its record. But it has a task before it compared to which its past achievements may be said to be little more than a scratching of the surface. The association has developed and placed on record facts as to how and where savings in fuel may be made. It has done much to supply the inspiration and develop the methods by which such savings were made effective; a great deal remains to be done, however, in these latter respects. The success of a fuel conservation campaign depends directly on the degree to which officers and men are inspired enthusiastically and faithfully to do their part as individuals.

Determining how and where the savings are to be made is largely an engineering problem. Getting the job done, however, demands a keen and thorough understanding of human nature, supplemented by the ability of a salesman or a promoter. It is not enough to attempt to educate men (I use this term to include both officers and men) as to the right way of doing a thing; some incentive must be offered to raise and maintain their interest at a high point. Men are not very different from children. Their attention is caught and retained for a while by one interest and then it restlessly moves on to another.

The men who are selling the idea of fuel conservation to their fellows in the organization must therefore not only study occasionally to change their methods of approach in order to maintain the interest of the men at a high point, but they must be so intimately in touch with the feelings of the men that they will guard against allowing the task to become ardu-

ous and will skillfully introduce into it all the spirit of playing a game. We have many experts to tell us how to conserve fuel down to the minutest detail. What we need is more promoters who can stir up enthusiasm and direct the energies of the officers and men along the right channels in carrying out these details.

For years many of us have felt that a large part of the problem of fuel conservation would be solved if we could develop some means of furnishing prompt and accurate records of fuel performance for each locomotive run. This looked most promising until we came to a fuller realization of the fact that almost every one on the railroad from the chairman of the board down to the call boy had some influence on the fuel performance. Why confine the measuring stick to the engine crew when so many other men enter into the problem of using fuel economically and efficiently?

While individual fuel performance records have their value, if they can be promptly and accurately obtained, would it not be better to get the whole team to work together as a unit to beat its own record, or that of its neighbors? The amount of coal used on a division and the train performance statistics can be determined fairly accurately. Two divisions may not be directly comparable, but suppose two divisions on the same or different roads, led in friendly competition by their superintendents, should try to see which one could make the best percentage of improvement. The idea is not new; its value in fuel conservation has been forcefully demonstrated within the past year.

When the fuel conservation promoter has this sort of a campaign going it will not be so necessary laboriously to teach the different men exactly how to do their part of the work. They will develop initiative and interest and will get after the expert or instructor rather than wait for him to get after them.

There is much indifference among the men in railroad service today. In the interests of the public the men, the management and the owners this must be overcome—and overcome quickly. One great difficulty in getting better results is that the men and officers are too far apart and do not really

know each other. If they did know each other better a lot of foolish misunderstandings would be wiped out. You can't carry out a program such as the one above mentioned without getting the men and the managements closer together.

There is another phase of the fuel conservation question which is deserving of special emphasis at this time. The Fuel Association is strong enough to take a real stand in attempting to correct some deep-seated abuses which reach back into the very heart of railway operation and management and bulk much larger than even the entire annual fuel bill of the railroads because they are a source of continuing waste not only in fuel but in other important items of cost of operation.

What will happen if instead of looking too intently upon fuel conservation as an end in itself we consider fuel performance as a barometer of efficient and economical operation? How many roads know what is the economical speed of a freight train over a given division? Why do they not

road? You ought to know! Do your train despatchers ever get out over the division, or are they glued to office chairs with distorted visions or imaginations as to what is really going on over the division? You ought to be the fellows to help supply the dynamite to jolt them loose.

All these things and others which you will call to mind—which the association has fully recorded in its proceedings—will affect fuel consumption as much or far more than can be done by the average engine crew. The call today is for the Fuel Association with its great influence to go to the very roots in tackling the fuel conservation problem in a really big way. The conditions are ripe; now is YOUR opportunity! Will you grasp it?

President MacFarland's Address

In his address Mr. MacFarland confined himself to matters pertaining to the welfare of the association, dwelling par-

Secretary-Treasurer

know? It is comparatively easy to determine. How much can the capacity of a division be increased and the economy of operation be improved by modernizing the power? What will it mean if really adequate facilities are provided for keeping the cars and locomotives in first class operating condition? What a wonderful saving could be made in fuel and other operating expenses if some real brains and money were expended in providing business-like locomotive terminal facilities instead of having engine houses which without much imagination can be described as "dark holes with walls around them!" How do you know that a certain type and size of locomotive is best suited to the conditions on your

particularly on the increase in the cost of conducting the work of the association, the largest part of which is involved in the publication of the proceedings. In calling attention to the proposed increase of \$1 a year in the annual dues, he reminded the members that the value of the proceedings is much more than the full amount of the dues. In referring to future work for the association, Mr. MacFarland suggested the development of a standard of fuel performance for locomotives. At the present time all fuel performance records are comparative, with no basic or potential standards, and he suggested the investigation of the possibility for the development of a formula for fuel performance in which

all the variables are included as factors, as an important subject for the consideration of a standing committee of the association.

REPORT OF COMMITTEE ON FEED WATER HEATING

The feed water heaters of today may be divided into the following general classes:

1. Waste gas heaters,
 - a. Gas tube,
 - b. Water tube.
2. Exhaust steam feed water heaters,
 - a. Closed and open types.

The gas tube feed water heaters are used by the various railroads where the Mallet type locomotives have been developed. This type gives a rise in temperature of 70 deg. when new, but in bad water districts this efficiency is lowered rapidly, due to scale forming on the heater surface.

Very little has been accomplished with water tube heaters of the waste gas type, although it has been the subject of much experimental work. Waste gases passing through the front end will average about 600 deg. in temperature, but the rate at which heat can be transmitted from these gases to the feed water is so low that it necessitates a very large heating surface in the smokebox to utilize any appreciable quantity of this heat.

Tests have recently been run on the Santa Fe system with a feed water heater of the Thompson (front end, water tube) type. After this heater had been four months in service, tests were made. The rise in feed water temperature was 30 degrees. An examination of the heating surface showed that in the four months' time 1/16 in. of scale had formed on the feed water heating surface. Tests were also made at this time, using a pump in place of the injector, and approximately 70 deg. rise in temperature was secured. No facilities had been designed whereby the scale could be removed, so it was removed after this test was made.

With proper means for the removal of scale and sediment the waste gas heater can be made an effective instrument for the removal of scale forming ingredients and other impurities before they are carried into the boiler.

The exhaust type feed water heaters, due to the lower temperatures, made it practically necessary to use a steam pump in place of the injector. This type is very attractive, due to the fact that the transfer of heat from steam to a heating surface is about ten times that of the transfer of heat from waste gases. This allows a rather compact system and the feed water can be brought to within 10 or 15 deg. of the temperature of the exhaust steam.

The closed type of exhaust steam feed water heaters in use in this country are as follows:

Weir feed water heaters, two of which are installed for test purposes on the Southern Railway. The troubles to date with this system have been that the water hammering on the pipes between the pump and feed water heater causes leaks and the expansion and contraction in the feed water heater itself causes leaks between the copper tubes and cast iron tube plates. A re-designed heater has been planned so as to take care of this latter trouble.

The second feed water heater system of this type developed in this country is that manufactured by the Locomotive Feed Water Heater Company. This heater has been in service on the New York Central, the Delaware & Hudson, and the Delaware, Lackawanna & Western railroads, and to date in the current year the following applications have been or are being made: Central Railroad of New Jersey, Fort Smith & Western, Canadian Pacific, Grand Trunk and Erie railroads. Additional equipments are being supplied to the Delaware & Hudson and the New York Central. The design is made so that the expansion and

contraction of the brass tubes is taken care of so that no leakage occurs.

In order to increase the effectiveness of the heating surface in the brass tubes a corrugated spiral agitator of thin brass is placed in each tube. This agitator more than doubles the transfer of heat across each square foot of heating surface, and the high velocity and scouring action of the water caused by its presence tend to prevent lodgment of scale or dirt on the heating surface. Not the slightest particle of scale or dirt has ever been found in the heaters now in service. No experience, however, has been obtained from very bad waters.

The open type heater in service is the McBride feed water heater and pump, manufactured by the Worthington Pump & Machinery Corporation. There are four in service on the Pennsylvania on locomotives in service out of Altoona, Penn. These have been in service for about a year. The feed water heater and pump are combined and are designed for a capacity of 60,000 lb. of feed water per hour.

The exhaust steam passes through an oil separator enroute to the feed water heater. No trouble has been experienced so far from oil passing through the oil separator with the exhaust steam and being delivered to the boilers with the feed water. On road tests the increase in evaporation per pound of coal was 14.4 per cent for the heater.

The development of the locomotive feed water heater is not a question of theory, but of design. A locomotive feed water heater must be capable of continuous operation under the most adverse conditions; it must not add appreciably to the difficulty of controlling water supplied to the boiler at any required rate; it should not increase the weight on driving wheels to the extent that it becomes necessary to reduce the dimensions of the boiler, and it should be applicable to existing locomotives without necessitating radical alterations.

The substitution of a pump for an injector is the most difficult problem connected with the feed water heating. It complicates the control of boiler feed, increases locomotive maintenance and weight, and is in itself not as efficient nor reliable an instrument as the injector. On this account the success of a locomotive feed water heating hinges very largely on the design of a successful pump, unless a practical heater of the waste gas type can be designed which will raise feed water temperatures sufficiently to effect an appreciable saving with the use of an injector.

No great progress in feed water heating can be expected until the solution of the problem is actively taken in hand by the railroads with a determination to make feed water heating a practical operating factor. The committee urges that the mechanical department of each railroad endeavor to lead in this development. We should each endeavor to be a pioneer in the practical application of the feed water heater.

The report was signed by E. E. Chapman (chairman), A., T. & S. Fe.; E. A. Averill, Loco, Feed Water Co.; O. S. Beyer, Jr.; E. V. De Vilbiss, Penn. System; J. S. Hampson, Rosengrant Coal Co.; F. Kerby, B. & O.; Monro B. Lanier, Monroe-Warrior Coal & Coke Co.; L. G. Plant, *Railway Mechanical Engineer*, and L. R. Pyle, Loco, Firebox Co.

Discussion

E. A. Averill (Locomotive Feed Water Heater Company) stated that there are three essential considerations which must be taken into account in judging the practicability of feed water heater devices. These are (1) safety, (2) reliability and (3) cost of maintenance. Following the ability to meet the requirements of these three points the questions of efficiency, weight of apparatus and cost of installation should be considered. Feed water heaters of the exhaust steam type have now been developed so that the requirements of safety and reliability are fully met; and while installations are too

few to permit accurate figures to be obtained as to the cost of maintenance under conditions which would exist were large numbers of locomotives equipped, experience indicates that the requirements of low maintenance cost have been met satisfactorily.

During the discussion the point was brought out that a saving in fuel greater than could be expected from the actual amount of heat reclaimed was observed in some tests of heaters of the waste gas type. This was attributed to the improved combustion resulting from the decreased amount of fuel consumed, which was great enough to permit the firemen to do a better job of firing than had been possible without the heater.

POSSIBILITY OF LIGNITE COALS

BY S. M. DARLING

Fuel Engineer, United States Bureau of Mines

The nation's resources in the way of solid fuel, while large, are not inexhaustible. During the last twenty years the population of the United States increased 42 per cent, and during the same period our coal consumption increased 172 per cent. Our annual coal consumption in 1919 was about 530,000,000 tons. Should the same rate of increase hold for the next two decades, the consumption in 1940 would be over 1,400,000,000 tons. And it is quite probable that we shall be called on to export many millions of tons annually to South America, Africa and the Mediterranean.

The nation's coal resources of all ranks total 3,553,637,-100,000 minable tons of 2,000 lb., nearly one-third being lignite. Of this lignite 964,424,000,000 is in North and South Dakota and northeastern Montana, approximately 23,000,-000,000 tons in Texas, and 7,404,300,000 tons in Alaska, and relatively smaller quantities in several of the other Western and Southern States. The lignite tonnage given above includes only true lignite (as distinguished from sub-bituminous).

The Carbonizing Process

I came to the conclusion early in my lignite work that the large way to utilize this fuel was to carbonize it; that is, break it up into its four main divisions of gas, oils and tars, ammonia, and solid residue, the latter being practically charcoal. The fact that the lignite does not coke in the sense that bituminous coal cokes, but rather crumbles, on being carbonized, makes possible a continuous and comparatively inexpensive carbonizing process. The costly element of labor is reduced practically to that required for directing mechanical operations.

THE PRODUCTS OF CARBONIZATION OF LIGNITE

(1) Gas, per ton of lignite (440 B.t.u. per cu. ft.).....	10,000 cu. ft.
(2) Oil and tar.....	15 gal.
(3) Ammoniacal liquor.....	65 gal.
(4) Carbon residue.....	955 lb.

The Gas—Of the yield of 10,000 cu. ft. per ton of lignite carbonized, 6,000 cu. ft. are required to carry on the process, leaving a surplus, costing nothing, of 4,000 cu. ft. of 400 B.t.u. per cu. ft., or a total of 1,600,000 B.t.u. yielding 160 hp.-hrs. This power is comparable in cost with that derived from natural gas, and is fully as cheap as most hydroelectric power.

Oils and Tars—Just what is the most profitable disposition in this country for the oil and tar products remains to be determined. Their treatment and marketing is an industry by itself. It is not probable that Germany will ever again control the coal tar product industry, and it is not unreasonable to expect that in the future a large part of the demand for tar products will be supplied from our immense stores of lignite.

Ammonia—The ammonia is contained in the gas and gas water; it may be recovered as ammonium sulphate, a valuable fertilizer, as anhydrous ammonia for refrigeration and

other commercial purposes, or it may be treated as a source of other nitrogen products, some of which are of vital importance in the manufacture of explosives.

Carbon Residue—Tests of carbonized lignite, for use in suction power-gas producers, in carload lots have proved it to be an exceptional and unexcelled fuel for this purpose. Its chemical composition, as shown by analysis, is about the same as that of Pennsylvania anthracite. For the production of power in this way carbonized lignite is fully equal to anthracite coal, charcoal, or bituminous coke, the standard fuels for such purposes. The carbonized lignite can also be burned satisfactorily on the automatic stokers and grates used to consume the smaller sizes of anthracite. Carbonized lignite briquets for domestic service have been made in carload lots, and, ton for ton, compare favorably with anthracite coal, and form an ideal domestic fuel in such rigorous climates as those of North Dakota and Alaska.

The territory naturally tributary to the Dakota lignite deposits embraces North Dakota, South Dakota and western Minnesota. Upwards of 2,000,000 tons of bituminous coal are shipped annually into that territory from Illinois, Indiana, West Virginia, Kentucky, and Pennsylvania. The average haul of this coal is 1,000 miles. If the Dakota lignite were put into stable and serviceable condition, by means of carbonizing and briquetting, this fuel demand could be supplied with an average haul of less than 400 miles. The average freight rate is about four mills per ton-mile. The tonnage mentioned does not include the anthracite shipped into this Dakota territory; this anthracite, carried in lake boats and distributed from the head of Lake Superior, amounts to about 1,500,000 tons annually.

To replace these 3,000,000 tons would require the carbonizing annually of 6,000,000 tons of lignite, yielding 3,000,-000 tons of solid fuel, 18,000,000,000 cu. ft. of surplus gas (costing nothing), 45,000 tons of sulphate of ammonia, and 60,000,000 gallons of tar distillates. The Texas lignite situation affords an equally great opportunity for economic saving. And there are many smaller deposits of lignite scattered over the Southern and Western States, where relatively smaller savings can be made in similar fashion.

Preserve the Source of Lubricants

Bringing this lignite onto the market as fuel, with its attendant production of oils, would release large quantities of petroleum and natural gas for other uses. Of our original supply of petroleum, 42 barrels per capita have been used and only 70 barrels per capita remain for the future. About half of the petroleum currently produced is used as fuel for steam raising. The possibilities in the use of petroleum and its products in connection with the navy, airplanes, the merchant marine, automobiles, motor trucks and tractors are so great and vital that before long the use of oil for steam raising will be regarded as an inconceivable folly.

Mr. Requa, Consulting Engineer of the Bureau of Mines and Director of the Petroleum Division of the Fuel Administration, puts the situation in forcible language:

"The operation of hydroelectric generators, of railways and trolley cars, of the machinery of the factories, of internal-combustion engines, for our battleships and our merchant ships—in fact, of all machinery—is made possible by the use of one product, and of one product alone—petroleum. For if there is no known satisfactory substitute as a lubricant its exhaustion spells commercial chaos or commercial subjugation by the nation or nations that control the future source of supply from which petroleum will be derived."

The urgent necessity is upon us now to begin to bring these enormous stores of lignite into use and make them do their proper part of the economic work of the nation. The carbonizing of lignite will place the lignite-bearing regions substantially on a par as regards fuel and power with those parts of the country that are favored with bituminous and

anthracite coal. It will give an equally good domestic fuel in the way of carbonized lignite briquets, better gas, producer fuel in the form of carbonized lignite, enormous quantities of gas to be used for fuel or power purposes, a large tonnage of fertilizer in the form of sulphate of ammonia, and a great amount of oils and tars.

Discussion

The discussion centered around the possibilities of using lignite coal in locomotive service and it was pointed out that the development of the use of lignite briquets depends on the building up of a market for the by-products. The experience in the by-product coke industry in the East indicates that this will be a process requiring considerable time. As an immediate means of making these coals available the possibility of using them in pulverized form has received considerable attention. Comparing the possibilities for the use of pulverized lignite with the bituminous coals from the Eastern and Central fields burned on grates, it was pointed out that the average saving in freight alone would amount to about \$1.60 per ton, while the cost of preparing the pulverized fuel, on the basis of a plant having a capacity of 1,000 tons a day, would amount to about 40 cents a ton delivered to the locomotive tender. This includes the interest, depreciation, taxes and insurance on an investment of \$250,000 required to install such a plant. In experimental work it has been possible to pulverize lignite with as high as 18 to 22 per cent moisture remaining in it. If this practice proves to be feasible commercially, it will eliminate the necessity for a drier of large capacity and the danger of combustion from the high temperature required in the drier to reduce the moisture to the low percentage ordinarily considered necessary in pulverized fuel practice.

The discussion also brought out the fact that some lignites can be burned in their natural form. This is being done very successfully on the Oregon-Washington Railroad & Navigation Company's line. The coal used is a black lignite or sub-bituminous with a heating value of less than 9,000 B.t.u. and 18 per cent moisture. To burn this coal, locomotives are built with large grate area and a large netting area in the front end. An unusually large exhaust tip is used and about one-third of the air is admitted over the fire through a baffle fire door. Because of the comparatively small amount of combustible in this fuel, it requires much less air per pound than the higher grade bituminous coals.

SANTA FE LOCOMOTIVE OIL BURNING PRACTICE AND FUEL PERFORMANCE*

BY WALTER BOHNSTENGEL
Assistant Engineer Tests, A. T. & S. F.

The Santa Fe System has approximately 3,160 locomotives, of which two-thirds use coal and one-third use oil as fuel.

The necessary procedure in converting a coal burner to oil is providing an oil tank of proper shape and size to fit the coal space in the water tank; removing grates, ash pan, and ash pan rigging and applying a fire pan with proper brick lining and burner; and arranging necessary piping on the tender and boiler back head of the locomotive, to regulate the oil outflow to the firebox. All pipe and pipe fittings should be extra heavy, the valves and throttle being of heavy design capable of carrying a maximum pressure of 250 lb.

Firebox and Flues

It has been demonstrated that button head radial stays should be eliminated and taper head radial stays applied. It is the practice to have all rivets countersunk and driven

*A. T. & S. F. locomotive equipment for burning oil was described and illustrated in a paper read before the 1915 convention, an abstract of which will be found in the June, 1915, issue of the *Railway Age Gazette*, Mechanical Edition, page 280.

flush. It is also considered good practice to scarf the door and flue sheet flange from the inner edge of the rivet hole to the outer edge of sheet, making the outer edge approximately 3/16 in. thick to prevent undue cracking from the rivet hole to the edge of sheet. It is not considered that firebox troubles are any greater in oil burning locomotives than in coal burners in proportion to the work performed. The troubles experienced in oil burning locomotives consist of cracks developing in the knuckle of the fire door hole, top flange of door sheet and flue sheet, leaky radial stays and staybolts, as well as cracks developing from staybolt to staybolt in the side sheet. Prompt and careful attention is necessary in boiler washing.

Should the side, flue or door sheets have patches applied by rivet or patch bolts, they are liable to give considerable trouble, and should the fireboxes be of the five-piece type, the longitudinal seams in the crown sheet would cause considerable trouble from leaking. It is Santa Fe practice to cover these seams with brick until they require renewal.

The life of a firebox and a set of flues is somewhat less in an oil burning locomotive than in a coal burning locomotive. The average for all locomotives, old and new, large and small, in all classes of service, shows that the life of staybolt fireboxes in coal is 10 years and 3 months and in oil 9 years. This cannot be used to predict the actual probable life of any one box, as the figures vary to a certain extent by reason of different local conditions. The average life of a set of flues in an oil burning freight locomotive is about 48,000 miles, and in a coal burning locomotive, same service about 65,000 miles. The life in passenger service is approximately 40 per cent higher and in about the same relation.

Engine Equipment

The Booth burner is used as standard on the Santa Fe. The patent on this burner expired in February, 1912, and it is made and tested in our own shops. Good results are obtained from 1½-in. burners on small locomotives, while the larger power is provided with 2 and 2½-in. burners. For the Mid-Continent oil, a 1½-in. pipe is used to convey the oil from the tank to the firebox, while with California and Mexican oil 2-in. piping is used to the firing valve.

The larger locomotives having 8,500 and 9,000-gallon water tanks, use an oil tank of about 3,400-gallon capacity. On the smaller locomotives having 5,000 and 6,000-gallon water tanks, the capacity of the oil tank varies from 1,800 to 2,250 gallons.

Comparison of Coal and Oil

The essential features in preparing to burn oil for locomotive fuel is the availability, extent of supply, and relative value of the oil, not at the well, but at the point of consumption.

The coal used on Santa Fe locomotives averages 11,500 B.t.u. and the oil 19,000 B.t.u. per lb. On this basis the theoretical heat value of one pound of oil equals 1.65 lb. of coal. After the ratio of coal to oil is obtained to agree with local conditions, the advantages to be gained by the use of oil may be considered by substituting in the following formula:

$$e = \frac{a \cdot b \cdot c \cdot d \cdot X}{2000} = \text{equivalent price of oil per barrel.}$$

$$d = \frac{a \cdot b \cdot c \cdot X}{2000 \cdot e} = \text{equivalent price of coal per ton.}$$

- a = Weight of oil per gallon pounds = specific gravity of oil times weight in pounds of one gallon of water.
- b = Number of gallons per barrel.
- c = Ratio of heating value of oil to that of coal in B. t. u.
- d = Price of coal per ton, dollars.
- e = Price of oil per barrel, dollars.
- X = Ratio of boiler efficiency, oil to coal.

The results of a number of recent tests on the Santa Fe show that the evaporate efficiency of oil is about 25 per

cent more than coal for hand fired and 40 per cent more than coal for stoker fired locomotives, that is, the factor X is 1.25 for hand fired and 1.40 for stoker fired locomotives.

The cost of changing a locomotive from coal to oil burning depends largely on the size of the locomotive. Recent figures show that the approximate cost of changing a modern locomotive of Pacific, Mikado or Atlantic type is from \$2,400 to \$2,500, including the construction of an oil tank, draft pan, petticoat pipe, oil burner piping, fittings, etc. This cost would also include the application and the usual overhead charge. A smaller locomotive, such as the eight and ten wheelers, can be converted at a cost of about \$1,800 to \$2,000 each.

Either the speed of the train or the tonnage is increased on an oil burning locomotive, due to the locomotive being worked to its maximum capacity at all times. A test made in 1919 shows that an oil burning Atlantic type locomotive handled an average tonnage of 750 tons, while the same kind of a coal burning locomotive handled 578 tons in the same class of service.

The Brick Arch in Oil Burning Locomotives

The paper also contains a report of tests on three oil-burning locomotives of the 2-10-2 type, all of the same class, to determine the effect of an arch tube supported brick arch on fuel performance, with the standard location of the oil burner at the front end of the firebox as well as at the rear of the firebox. These two arrangements were compared with the standard firebox arrangement, which does not include a brick arch.

The data for the individual runs during these tests, as

lower front end temperature. Another explanation for lower efficiency of the arch with oil, is that radiant heat is not utilized to the best advantage with an arch, as the arch shades part of the firebox.

As a general conclusion, taking the present standard arrangement with front end burner and no arch or arch tubes as a basis, the data secured on these tests show that the advantages resulting from the use of an arch tube supported arch with either the front or back end burner arrangement are more than offset by disadvantages and, from these tests, the installation and maintenance of the arch cannot be justified in oil-burning locomotives.

Discussion

The discussion centered around the difficulty resulting from the accumulation of carbon on the bottom of the draft pan in front of the oil burner on oil-burning locomotives. This is being experienced in some cases where oil has only recently been adopted as locomotive fuel, especially where the heavy gravity Mexican oils are in use. On roads which have had considerable experience, the difficulty has been overcome, largely by care in the location of the burner, to keep the flame properly centered in the firebox and away from the bottom of the pan, and by admitting air around the burner, principally under and at the sides of the burner.

In discussing the Santa Fe arch tests, J. T. Anthony stated that experience on other oil-burning roads indicates a saving of from five to eight per cent where the arch is used. He took exception to the statement that the arch tended to shield part of the firebox from direct flame radiation, as the temperature of the arch makes it a radiating medium itself. He

GENERAL SUMMARY OF OIL BURNING TESTS, WITH AND WITHOUT BRICK ARCH

Boiler and superheater	76.4	75.3	75.6	74.5	76.0	74.0	74.5	73.5

All runs were made between Needles, Calif; and Seligman, Ariz., 149 miles.

Firebox arrangements:
 A = Without arch tubes or arch; burner at the front end of the fire pan.
 B = With arch tubes and arch; burner at the back end of the fire pan.
 C = With arch tubes but no arch; burner at the front end of the fire pan.
 D = With arch tubes and arch; burner at the front end of the fire pan.

well as the average, show a slightly better fuel performance for the locomotives without the arch than for those with a brick arch. However, the atmospheric temperature averaged slightly higher during the runs made without the arch than for those with the arch, which would be favorable to the former in a lower radiation loss.

The data show no saving in fuel, if anything a lower efficiency for the arch, in comparison for the present front end burner arrangement without arch. This can be explained by noting that with proper drafting, without arch as well as with arch, the locomotive can be fired without showing smoke, and having as low a front end temperature without as with the arch. Obtaining complete combustion in the firebox in either case, further economy could only be obtained by absorbing more of the heat from the gases and getting a

admitted that where a boiler efficiency as high as 76 per cent was obtained without the arch there was not much range for improvement left for the arch, but doubted the ability, day in and day out, to maintain such a high efficiency.

REPORT ON FRONT ENDS, GRATES AND ASH PANS

The committee presented data for comparison of two types of grates from tests of two classes of coal, namely, Gallup and Kansas on the Santa Fe. The object was to determine what, if any, saving could be effected by using table grates in place of finger grates in locomotives burning Gallup coal. This coal, obtained from Gallup, New Mexico, is a semi-bituminous coal, having the following analysis:

Moisture, per cent.....	8.25
Volatile matter, per cent.....	29.91
Fixed carbon, per cent.....	51.46
Ash, per cent.....	10.38
Sulphur, per cent.....	0.64
Calorific value of coal as received B. t. u., per pound.....	11,484
Calorific value of dry coal, B. t. u. per pound.....	12,516

The test was made between Belen and Gallup, New Mexico, in May, 1919. The locomotive used for this test is a single expansion Mikado type equipped with a Duplex stoker and superheater. It was new, having just been received from the Baldwin Locomotive Works. The front end draft arrangement and the brick arch arrangement remained the same, and in the comparison of data of finger and table grates the same fireman was used throughout the test.

The standard finger grates for Gallup coal were installed first, and the brick arch maintained eight bricks high in the center and intermediate rows and seven on the side rows, and all set down against the tube sheet. With Gallup coal, it has been found most economical to run the arch down against the flue sheet and at least seven courses high, on account of stack losses. The standard Gallup coal grates have 5-in. openings between the fingers, while the clearance between the bars on the table grates is 3/4-in. with 5/8-in. slots for air passage up through the bars. The percentage of air opening is approximately 37.8 per cent with either design.

The locomotive was run with full compensated tonnage rating, namely, 2,300 tons, Dalies to Gonzales, and 2,700 tons, Gallup to Gonzales.

The million-foot pounds of work done at the drawbar indicated a higher average drawbar pull, a greater amount of total work done, as well as a greater amount of work per hour while working steam with the table grates than with the finger grates. This is the reason for the table grates using more coal and giving poorer evaporation than the finger grates, as the harder the locomotive is worked, particularly where there is much fine coal or slack, the greater the stack loss.

The table grates do not drop any fire and very little ash except when being shaken, while the finger grates drop considerable fire in certain portions where the fingers are cut

coal consumption with the table grates is due to insufficient air admission. While the air openings are calculated to be the same, the ashes or contents of the firebox pack down over the slots in the table grates and there is not the same chance to loosen it up by shaking as with the finger grates. The steaming of the locomotive was about the same with the table grates as with the finger grates.

When all things are taken into consideration, the saving in coal of table grates over the standard Gallup coal finger grates, or vice versa, is very small. Under certain conditions one will show a saving, while under other conditions the other grates may show a saving.

A similar test was made on the road between Argentine and Emporia, Kansas, a distance of 108 miles, with Kansas coal. The same type of locomotive, No. 3209, was used on this test as with Gallup coal and with the same equipment.

The data on the table grates were obtained for the most part by an observer on the locomotive after the test with the dynamometer car had been finished. On most of the trips with the observer on the locomotive, a test on a perforated arch in comparison with the standard seven course arch was carried at the same time. However, the results indicate that the perforated arch cut a very small figure in the saving.

Evaporation is the proper basis on which to make a comparison between table and standard grate. From a summary of dynamometer car data there was shown to be an average saving for the round trip of 8.0 per cent. Based on tests without the dynamometer car the saving averages 10 per cent for the round trip. Under all conditions there was some saving in favor of the table grates, and a conservative estimate would be from 1 to 1 1/4 tons of coal per trip.

The table grates save coal by preventing it from falling through into the pan only partly burned. The loss from this source is very noticeable with the coarse grates now used, particularly when the coal is fine and starting out of a terminal when the fire is light. Part of this loss could be eliminated by using finger grates with fingers closer together, such as those used for Gallup coal.

There is a considerable loss due to finger grate bars having

NOTE—"A" is the average of five trips in each direction, with finger grates and an eight course arch. "B" is the average of two trips in each direction with finger grates and a perforated arch. "C" is the average of three trips in each direction with table grates and an eight course arch.

short to clear obstructions in the corners of the firebox. The shape of the pan (the high sides) causes the hot ashes and fire to sweep up along the side of the cab into the engine-men's faces when a high side wind is blowing. The table grates were very popular with the enginemen on this account; also, on account of being easier to shake. There is very little need of a power grate shaker with table grates and Gallup coal.

Aside from the coal being a little finer and the locomotive being worked a little harder on trips with the table grates, which incurs a greater stack loss, it is possible that the larger

to be replaced on account of fingers being burned off which loss would probably not be so great with the table grates.

Front Ends

During the testing of the Mikado type Locomotive 3209 just referred to, a variable exhaust nozzle designed by Mr. Stevens, a boiler maker on the Santa Fe, was applied for test. This device can be regulated from the cab and gives a discharging area equal to a nozzle area anywhere between 5 1/2-in. and 6-in. diameter. The idea of the inventor was to open up this nozzle when the locomotive was steaming

freely and to close it down at gradients of 1/16 in. when for any reason the locomotive did not steam so freely.

When first applied, in February, 1919, no difference could be detected in fuel consumption, and it was found necessary to put a diamond split in the top. However, as weather conditions got better, the nozzle was run practically wide open all the time. In its operation the nozzle was run either wide open or closed. The specific gradations in closing were not utilized by the enginemen. The chief disadvantage of the variable exhaust nozzle is that if not worked frequently it becomes inoperative in a short time by being stuck up due to the exhaust gases.

At the fourth annual convention in 1912, an exhaustive paper was presented to this association showing the great possibilities in fuel saving and the further possibilities of increasing the power of locomotives by the elimination of back pressure. Information now comes to the committee that a simple and effective drafting system has been developed based on the fundamental assumption in the paper on back pressure, previously referred to, that there was sufficient energy in the exhaust steam to draft the locomotive with a maximum of four pounds back pressure on the cylinders.

The essential features of this system are an exhaust volume chamber and a governing variable exhaust nozzle which opens under very low static pressure and which has a variable opening with each exhaust blast. The variable opening and constant automatic agitation of the wings is most essential in maintaining a variable exhaust nozzle.

In the committee's last report attention was called to the Master Mechanics' formulæ for the design of stack and front end, showing that they are not properly applicable to present power. The Lewis drafting system, with its exhaust blast of very large contact area of steam and exhaust gases, and its unusually large stack, are convincing testimonials that we should no longer abide by this rule of thumb design, but that we should make investigations to find the limit of design which will give the greatest efficiency of the exhaust blast.

The report was signed by H. B. MacFarland (chairman), A. T. & S. F.; W. J. Bohan, Nor. Pac.; E. B. DeVilbiss, Penn. System; J. P. Neff, American Arch Co.; Frank Zeleny, C. B. & Q., and C. C. Higgins, St. L.-S. F.

USE OF CARBOCOAL ON LOCOMOTIVES

BY GEORGE E. SCHERICK, JP.

Fuel Engineer, International Coal Products Corporation

In the firing of bituminous coal many schemes have been tried to promote better efficiency and some of these have met with considerable success. But in spite of all attempts toward better economy the locomotive boiler remains today one of the chief offenders in the extravagant use of fuel. There can be no doubt that the continued demand of the public for abatement of the smoke nuisance will force the railroads to the use of a smokeless fuel or to electrification of their roads in their larger terminals. The limited supply of anthracite in the country makes it unlikely that anthracite can be used generally on railroads, and it is evident that there is a good field for a fuel comparable to anthracite but manufactured from bituminous coal, with a saving of the valuable by-products.

Carbocoal is a dense, smokeless fuel formed by carbonizing bituminous coal. Any coking or non-coking bituminous coal or even lignite can be used in the process, although some coals are more desirable than others. Carbocoal compares very favorably with anthracite coal and has about the same analysis, but it burns with a much less draft. It is manufactured from bituminous coal by carbonization in two stages. The raw coal is first crushed and then fed continuously to horizontal retorts, operated at a relatively low temperature. The volatile matter in the coal is reduced to about eight per

cent. This low temperature coke or semi-carbocoal is then ground, briquetted with pitch, and the resulting briquets are carbonized at a temperature corresponding to that used in coke ovens, the by-products again being collected as in coke-oven practice.

The resulting briquet is a smokeless fuel resembling anthracite in its properties and differing considerably from ordinary coke, particularly in that it is a soft form of carbon and much more free burning than coke.

Several carbocoal tests have been made by various railroads in the east, and the results as a whole have been very satisfactory, especially as these tests can only be considered of a preliminary nature.

The first test run on a locomotive with carbocoal as fuel was made on May 21, 1917, and was run to ascertain the possibilities and flexibility in handling when fired on a regular locomotive grate with its draft system. The engine (a switch engine) was equipped to burn anthracite, fuel oil or bituminous coal, and as reported by the superintendent of motive power of this railroad, who was keeping a close watch of this locomotive throughout the day, "the performance on the road was better than with either hard or soft coal. The engine steamed more freely and the fire could be kept in more satisfactory condition, as the briquets did not clinker at all but simply burned up to a fine ash which could be shaken through the grates. In this respect it was superior to any of our ordinary fuel."

It was necessary to shake the grates only four times from the time the fire was originally built. At no time during the test could any smoke be detected coming from the stack. The briquets, despite the many times they had been shoveled from the period following their manufacture to the time they rested in the tender, appeared without any mutilation and with a marked absence of slack and fines. No difficulty was experienced in maintaining a full head of steam. On six occasions it was necessary to start the blower on the engine, whereas the engine crews stated that with coal as a fuel on this particular work it was necessary to keep the forced draft in operation the greater part of the day.

In September, 1917, the Carolina, Clinchfield & Ohio ran a series of two tests with carbocoal. These were run over the same road from Kingsport to Soldier, a distance of 22 miles, with 43, 50-ton cars in the train, and as far as was feasible external conditions were kept constant. No instructions were given the fireman as to the proper methods of handling carbocoal. There was no opportunity to try out the fuel in advance. The firemen in this locality were accustomed to firing high volatile bituminous coal, while the carbocoal corresponds in many ways to anthracite coal.

CAROLINA CLINCHFIELD & OHIO TEST OF CLINCHFIELD CARBOCOAL

Water evaporated per pound of coal.....	7.77	7.30	7.53
Equivalent evaporated per pound of coal.....	9.36	8.83	9.09
Fuel consumed per ton mile, train load.....	.184	.250	.217

*Allowance has been made for fuel due to safety valves being open at least 19½ min.

In addition to these tests a demonstration was made on the Baltimore & Ohio. This demonstration was witnessed by some of the leading citizens of the community in which it was made, and gave entire satisfaction as a smokeless fuel.

Carbocoal can be stored in unlimited quantities without danger of fire from spontaneous combustion. The storage space per ton for carbocoal is but a few per cent greater than

for coal; further, the carbocoal does not weather and slack as many coals do on storage.

Discussion

Several inquiries were made relative to the commercial possibilities to the railroads and the cost of production. The first commercial plant will commence operation in the Clinchfield district in July and no production costs are available. An estimated investment of three million dollars will provide a capacity of 1,000 tons daily with a net return under the present market of one million dollars annually.

ECONOMICS OF THE FUEL OIL SITUATION

By EUGENE McAULIFFE
President, Union Colliery Company

Within twelve months the fuel oil situation, insofar as present and future supply, as well as unit costs, are concerned, has undergone startling changes. One year ago we were alone concerned with the economical consumption of fuel oil; today there is a national, even international, feeling that the period of fuel oil consumption for steam making purposes is substantially behind us.

After practically effecting the consummation of a very extensive oil burning program the Naval Department asking in March last for Pacific Coast bids on 4,500,000 barrels of fuel oil, received but one bid covering a delivery of but 602,000 barrels, at a price of \$1.95 per barrel. In April bids were requested for Atlantic Coast deliveries, five tenders returned, covering an entirely insufficient supply, the price for bunker oil ranging from \$2.07 to \$3.76 per barrel of 42 gallons. A similar fuel problem confronts the American merchant marine, the completed program of the United States Shipping Board, aggregating 10,000,000 dead weight tons, of which 2,000,000 tons will consist of coal burning vessels and 8,000,000 tons of oil-burning vessels. The estimated fuel oil requirements of the Shipping Board for the year 1920 are forty million barrels, and for 1921 sixty million barrels.

When we consider that the necessity for maintaining a navy will not cease until the end of the existing generally used form of government, or until the millennium arrives, both of which are perhaps quite remote, it would seem very plain that the requirements of the United States Navy, equipped to carry and burn oil will take precedence over any other demand, and it is equally reasonable to assume that after the American people have spent not only millions but billions in the upbuilding of an American merchant marine, that its fuel oil requirements will take position only second to that of our battleships. The statement of men who should know, that 1920 and 1921 will mark the peak period of oil production with a steady decadence from this time forward justifies serious consideration of the oil problem. The United States Geological Survey estimates that with the close of the year 1919 we have taken approximately five billion barrels of oil out of the ground and that the estimated oil reserve yet in the ground is six and one-half billion barrels. Whatever does the future promise?

Between 1909 and 1918 the number of automobiles and trucks increased 1700 per cent, and the consumption of gasoline for automobile purposes jumped from 13,000,000 to 85,000,000 barrels, or 650 per cent, while the production of crude oil increased 95 per cent. Today we operate 7,600,000 automobiles and motor trucks, and 350,000 tractors, and the 1920 construction program totals 2,000,000 automobiles and motor trucks. Power boats, aeroplanes and minor power pumping plants employ thousands of internal combustion engines, all calling for oil and gas. It takes a half pint of oil to translate a ton of coal into power by way of the steam engine, to consume the power so generated takes much more. Without petroleum we could no more grease the bearings and spindles of industry than we could light our great build-

ings and streets with tallow dips. The total available animal fats, together with that which might be possible to extract from sea life in the period of a year, would not even dimly light and poorly lubricate the world for one-tenth of that time, even though food fats were taken to swell the supply. The government has thrown open for drilling 6,500,000 acres of national oil reserve, but these lands located in California and Wyoming will not add materially to our supply. In 1919 twenty-nine thousand wells were driven, to success or failure; of these 6,000 were dry, 2,000 returned gas without oil, the drilling expense estimated at \$600,000,000.

The translation of oil into steam will quickly cease, through the pressure of economic forces and the transportation companies must perform sense the changes that are taking place in the fuel oil world. Millions of dollars were saved in past years by the substitution of cheap crude oil and refinery residuum for coal in locomotive fireboxes. Only twelve years ago it was difficult to force the skimming plants of Texas and Oklahoma to take sufficient gasoline out of the crude to make its use on a locomotive safe. The railroads who then absorbed the residue left after the taking off of the lighter distillates built up a comfortable refinery traffic for their rails, but a complete return to coal fuel is now imminent. To avoid the necessity for summary and violent changes the work of shifting fuels should be undertaken at once and conducted quietly and gradually. Fifty million barrels of fuel oil represents twelve million tons of coal. This is not a large tonnage if it were not for the fact that the major portion of the oil is consumed where the coal production is relatively small.

Other Papers

The report of the committee on Fuel Stations which was here presented will be abstracted and published in a later issue of the *Railway Mechanical Engineer*.

M. A. Daly, Northern Pacific, chairman of the committee on firing practice, conducted before the association certain simple chemical experiments which are used in the Northern Pacific instruction car to instruct and interest engine crews in the principles of combustion. The discussion showed considerable interest in these methods.

The committee on pulverized fuel reported that efforts to secure reliable comparative cost data during the year were unproductive and the discussion indicated a desire on the part of members for information of this character applicable to decisions on local problems rather than further data of a general character about the process. Such information as was brought out in the discussion indicates that about the only extensive experience in locomotive service has been where low grade, cheap coals, such as anthracite silt, are available.

M. B. Morrow, Canmore Coal Company, Canmore, Alberta, addressed the association briefly during the closing session.

Association Business

The secretary-treasurer's report showed a gain of membership of 311 during the year with a total of 1,297. Owing to the increase in the cost of printing amendments to the constitution and by-laws were passed increasing the annual dues from three to four dollars.

The question of affiliation with the American Railroad Association was brought up and action was deferred till the next convention.

The following officers were elected for the ensuing year: President, J. B. Hurley, Wabash; vice-presidents, W. L. Robinson, Baltimore & Ohio, W. J. Bohan, Northern Pacific, and R. Bradley, Boston & Maine; executive committee: P. E. Bast, Delaware & Hudson; J. N. Clark, Southern Pacific; Robert Collett, New York Central; C. C. Higgins, St. Louis-San Francisco; J. M. Nicholson, Santa Fe; A. W. Perley, Oregon-Washington Railroad & Navigation, and T. Duff Smith, Grand Trunk Pacific.

MODERN VS. OBSOLETE ENGINE TERMINALS

Advantages of Modernized vs. Antiquated Engine
Terminals Considered from Many Different Angles

BY C. G. LANCE

Shop Engineer, Seaboard Air Line

DURING the past ten years the average size and weight of locomotives has increased from 25 to 30 per cent. In addition the complications brought about by the various specialties required on large modern locomotives, such as Power Reverse Gear, Stokers, Grate Shakers, Coal Pushers, Super-heaters, Headlight Dynamos, Automatic Fire Doors, Duplicate Air Pumps, of large size or cross compound, and the flexible steam and exhaust connections, intercepting valves, duplicate valve gears and other devices brought into use on articulated compounds, have greatly increased running repair and maintenance work. In fact, owing to the large size and weight of important parts and countless number of additional devices to require attention, that were comparatively unknown and unnecessary on small engines, the volume of work has increased in a larger proportion than the size of locomotives.

Increased tonnage and faster movement made possible by modern motive power have necessitated improvements in the physical condition of railroads that have been beneficial to operating and maintenance of way departments. Heavier rail and bridges, longer passing tracks, larger classification yards, reduction in grades and better roadbed have made it easier for the departments mentioned to care for their work although even these improvements have not kept pace with requirements and during Federal control were for the most part discontinued. The same consideration has not been given to the requirements of the mechanical department with the result that many roads are making vain effort to maintain heavy modern power at inadequate and obsolete terminals. Few modern engine terminals have been provided, except on some of the larger and far-sighted roads, and for the most part the terminals now being used to handle Mallet, Santa Fe, Mikado, and Heavy Pacific type engines were built from 20 to 25 years ago, when the largest engine was of the 10-wheel type. This is true of many important points handling from 500 to 900 engines per month. Spasmodic attempts have been made to modernize some of these old facilities by putting in 100-foot turntables and adding extensions to old roundhouses, but the fact remains that large power is still being handled with extreme difficulty in small crowded terminals where there is no possible opportunity to do more than makeshift repairs.

The Cost of Inadequate Engine Terminals

Annual improvement budgets are made up by most roads, giving in detail the needs of every department. The Mechanical Departments always bring up the question of adequate terminals showing the money justification and urging the provision of their minimum needs. For the most part discussion of these matters is closed with the statement that "they got by last year with what they had and ought to be able to run another year." Small consideration is given to the cost of handling power in obsolete terminals and its effect on future life and condition of engines. There are many terminal points that would be abandoned if a cost analysis was made which took into consideration the depreciation of power improperly maintained, the cost in road overtime due to poor work or terminal delays, fuel and labor expended standing engines on in and outbound tracks under steam on account of insufficient house room, ash pit facilities, etc.

At least one hour's time can be saved in the time required to make running repairs to each locomotive handled, considering that the average value of a locomotive in good working order is at least \$50 per day, time saving of one hour would mean a gain of \$2 per engine handled on account of increasing the total number of hours engines would be available in good working order. In addition to this on account of eliminating practice of mechanics attempting repair work on tracks outside of roundhouse, which naturally due to difficulty in handling materials and distance from tools increases cost of this work, a saving of at least one hour's time of one mechanic at 72c. per hour and one helper at 49 c. per hour or a total of \$1.21 per engine will be made. This combined with the \$2 time saving will amount to \$3.21 saving per engine, and on an average of 50 engines per day the total annual saving will be \$58,582.50. To this can be added a loss of \$30,000 per annum which represents the actual cost of fuel burnt, and the time of engine watchmen that are required to keep up the fires of engines that are either waiting for vacancy in roundhouse or engines which have been removed from roundhouse in order to make room for others, and are kept under steam for unnecessarily long periods, waiting until they are called to take out trains. This makes a total annual saving of \$88,582.50, which would result from

improved engine terminal facilities that would not cost over one million dollars, although the return assured on an investment of that magnitude would be almost nine per cent.

Obsolete Roundhouse Throws Burden on Back Shop

There are cases of old roundhouses having new and large turntables installed where the edge of pit is so close to front of house as to interfere with moving or handling of engines and preventing adjacent tracks being used for large engines on account of insufficient clearance. At some engine terminals the facilities are so inadequate that all trailer wheels removed, driving wheels dropped and similar work must be done in back shop under crane, taking up valuable engine pits and interfering with classified repairs. This, of course, can only occur at division shop points but would never occur at all if proper consideration to improvement needs had been given.

Generally roundhouses are low, smoky and in the South they are not provided with adequate heating facilities on account of the so-called short mild winters. In spite of the short mild winters referred to a surprising number of stoves are required and many instances of frozen piping and frozen up engines occur during at least five months of the year. The money wasted in fuel and attendance to stoves, thawing pipes and engines and highly paid mechanics loafing around stoves would in most cases pay for the installation of extensive heating systems and show a saving.

Some of the Improvements That Are Needed

The life of firebox, stay-bolts and boilers can always be prolonged by washing with hot water. Washing with cold water which must be done in order to get engines back into service promptly at points having no boiler washing plant is very injurious and causes leaky tubes, broken stay-bolts, cracks and other defects. There is a surprising lack of facilities for washing and filling boilers although it has been definitely proven that fuel is saved through filling boilers with hot water near the boiling point and by having clean sheets and tubes. The actual fuel saving due to filling boilers with hot water will amount to at least one-half to three-quarters of a ton of coal per engine handled, which would alone justify the expenditure, not considering the fuel savings made on account of clean tubes and sheets or the decrease in boiler repairs required and the saving in time required for washing boilers.

The machinery equipment at many roundhouse points has long been accumulated through the simple expedient of sending worn out and obsolete machinery no longer useful in main or division repair shops. This is a serious and expensive mistake and machinery of this character should be scrapped or otherwise disposed of. The roundhouse machine work must be done without delay, as in many cases there are no extra parts on hand and any manufacturing or fitting must be done accurately and promptly which cannot be done on worn out or broken down tools. Only the most modern machine tools should be installed and the small hand tools should be of good quality and furnished in such quantities as to avoid delay when more than one mechanic is required to do similar work. In old roundhouses handling heavy power delay and difficulty is usually experienced handling rods, cylinder heads, cross-heads, steam chests and other heavy parts by hand. Jib cranes have been put in for handling front cylinder heads and steam shafts, but overhead crane service should be provided in both roundhouses and shop to reduce the labor costs to a minimum.

Coaling and Ash Handling Facilities Require Particular Attention

The size, type and location of coaling and ash handling facilities contributes greatly to the successful operation of engine terminals. Many ash pits are the old style depressed track type that require deep pits and tracks supported on

columns. These are hard to maintain and require large labor forces to handle cinders. In crowded yards this type of pit takes up much valuable room, on account of the approach to the depressed cinder loading tracks. Any type of cinder pit installed should provide for prompt mechanical removal of cinders and elimination of expensive hand labor, and delay to engines, pits having overhead crane service or bucket conveyors being preferable. Low first cost has generally been the consideration when erecting coal chutes and results in annoying and expensive delays when repairs are necessary account of poor design or light construction. Coal chutes should be provided with powerful rugged hoisting mechanism whether operated by steam or electricity, serving more than one track to eliminate all possible delay. Sand drying and delivering facilities should be arranged so coal and sand can be taken at the same time. There should be several water cranes located at the most convenient points.

A Comprehensive Plan Essential

I have endeavored to call attention to a few of the main features that will have to be remedied before efficient and economical operation can take place and power kept at its maximum efficiency. The longer the provision of adequate facilities is delayed, the greater will have to be the final expenditure. A comprehensive improvement program covering the requirements for the future as well as present needs should be mapped out by every railway and followed through to a conclusion. Care should be taken not to locate terminals where there is insufficient room for extension, thereby making it necessary to move to new location when extensions are required. Many improvements have been made in the past of light or semi-permanent construction—with an eye to economy in first cost. This is a serious error in judgment for buildings of this character soon deteriorate, are expensive to maintain, and in wet or cold weather work is interfered with and machinery and equipment damaged.

The most economical plan when providing facilities, taking into consideration all features, is to provide well planned and constructed facilities properly located, just a little larger than needed to care for immediate requirements, equipped with the best machinery and most up-to-date equipment obtainable. The execution of this plan will result in an actual money saving, a decrease in engine failures and terminal delays, prolonged life and increased efficiency of motive power.

FEDERATED AMERICAN ENGINEERING SOCIETIES

A total of 134 delegates, representing 66 engineering and other technical organizations, responded to the invitation of the Joint Conference Committee of the four founder societies to meet in Washington, D. C., on June 3 and 4. The result of this convention was the formation of The Federated American Engineering Societies, composed of societies and affiliations and not of individuals. The first action after the election of the chairman and secretary was the presentation of the following resolutions:

Resolved, that it is the sense of this convention that an organization be created to further the public welfare wherever technical knowledge and engineering experience are involved, and to consider and act upon matters of common concern to the engineering and allied technical professions.

Resolved, that it is the sense of this convention that the proposed organization should be an organization of societies and affiliations and not of individuals.

The discussion which followed concentrated upon these resolutions. This brought forth a variety of opinions. The representatives of the American Association of Engineers, evidently believing that the new organization would possibly interfere with, or in some ways duplicate, their efforts in public welfare work, carefully sounded out the assembly on

the question of a society composed of individuals. Outside of the attention given the matter by this society the question of an organization composed of individuals received but little attention, the chief objection to it being the difficulty attending its promotion. The fact was brought out that practically all of the active members of the local and national societies were members of two or more organizations and that as such was the case there would be great difficulty in securing a membership large enough to promote and carry on the desired work.

With the sentiment in favor of an organization composed of societies and affiliations, the American Association of Engineers yielded its point and, joining with the rest, made the vote in favor of adopting the resolutions unanimous.

Constitution Is Adopted

The constitution, as presented at the second day's session, was finally adopted with a few minor changes and one addition, a publicity clause insuring the maximum co-operation with the press. In brief, the constitution provides for an organization to be composed of national, local, state and regional engineering and allied technical organizations. The management will be vested in a body known as the American Engineering Council and an executive board composed of 30 members of the council, including the president, the four vice-presidents and the treasurer of the council. Representation on the council will be on a basis of one member for the first 100 to 1,000 members of a society and one for every additional 1,000 or major portion thereof up to a maximum of 20. While it is in some measure true that this plan would give the nationals too large a relative representation it was shown that the affairs of the nationals and the locals were so closely allied and the memberships of the two were so closely interwoven that in reality it would make but slight difference. Members of the executive board will be elected by districts, the proportion being the same as on the council.

Funds for the financing of the new organization will be provided by contributions from each member-society equal to \$1.50 per member for the national and \$1 per person for the local, state and regional organizations. Several local societies objected to this on the basis that a large part of their membership consisted of non-voting members paying small dues and that the tax would be out of proportion.

Under the circumstances the constitution was interpreted to read that as each organization must submit its constitution and by-laws to the executive board before becoming a member, it could at that time submit a statement showing the number of voting members or members upon which it wished its representation based. The board would then be in a position to judge fairly and to decide in each case what would be equitable.

Provision was made for co-operation with and the encouraging of local, state and regional organizations in the formation of affiliations for the purpose of considering public welfare matters. In inserting a publicity clause, a provision was made for the formation of a publicity committee and in order to further their work all meetings, except executive sessions of the board, were to be open meetings, and the books and minutes of the organization were to be open for transcription at any time.

The constitution and by-laws were adopted by the conference by a unanimous vote of all voting, although several societies refrained from casting a vote, even though it was understood by all present that any decision made by a delegate was not binding upon his society. The largest organization not voting was the American Association of Engineers, whose representatives refrained from voting on the basis that as they disagreed with certain sections of the constitution they did not feel at liberty to ratify it. They did wish, however, to assure the conference of their sincere intention

to co-operate to the best of their ability and along such lines as the Federated American Engineering Societies would formulate, leaving the question of ratification to a vote of the association itself.

The only delegation present with full power to accept or refuse any action of the conference was that of the American Society of Mechanical Engineers, who ratified the constitution in the name of that society. The representatives of this society further stated that the society was ready to enter the federated societies at any or such time as the latter found convenient to handle such work.

Significance of the Federation

A study of the constitution adopted reveals the underlying significance of the federation and outlines in some measure the scope of its future activities. The following statement from Article II of this document is worthy of note:

Service to others is the expression of the highest motive to which men can respond, and duty to contribute to the public welfare demands the best efforts that men can put forth; therefore, it shall be the object of this organization to further the interests of the public through the use of technical knowledge and engineering experience, and to consider and act upon matters common to the engineering and allied technical professions.

In this paragraph is revealed a splendid appreciation of responsibilities of the engineering profession to the public welfare. The engineering profession today exercises a greater control over those forces of nature that affect our material welfare than any other profession; although the youngest, it has acquired in a brief space of time the greatest potentialities for doing good. The organization of this federation is, in fact, a belated appreciation of the dignity and power of the profession as a whole, and a desire to put into concrete form an expression of the ideals of the engineer.

In this movement the engineer both sacrifices and gains something affecting his personal interests. Affiliation with the federation represents a subordination of the purely personal objectives to the public good, but at the same time the engineer has gained much. The federation should go a long way towards dignifying the profession and towards commanding the respect of all other interests. It should tend to put the engineering profession in its proper plane and to put the individual engineer in a position where he cannot be exploited.

Federation and the Railroads

The formation of this important federation should mean something to men of the engineering profession in railroad service. While a few engineers have made a brilliant success out of a railroad career, the profession has not as a whole fared favorably at the hands of the railroads, and this in turn has reacted unfavorably on the railroads themselves, until we have a situation in which but relatively few young engineers are engaging in railroad employ.

Railroad work should afford a splendid opportunity for the engineer, its technical problems are immense and it has been demonstrated that the trained engineer often makes a most proficient executive in the operating as well as the technical field. It is not too much to say that the engineering profession affords the best if not the only salvation for the railroads in their endeavor to perform a great public service with insufficient and inefficient equipment. The Federated American Engineering Societies can do much towards improving the standards of remuneration for engineers and towards creating appreciation of the value of engineering service; it can also point out the engineer's responsibility to the public and public service in which the railroads must figure prominently.

TWO ADDITIONAL STATES REQUIRE CAR REPAIR SHEDS

Recent statutes passed by the states of Minnesota and North Dakota require railroads or other concerns doing car repairing to provide suitable houses so that the men engaged in this work are protected from the weather. The Minnesota law requires that such buildings shall be constructed wherever there are six men engaged at one time in the repairing of cars, car trucks, etc., while in North Dakota the minimum is five men. Exception is made in the case of repairs to cars while they are en route as part of a train.

The Minnesota law goes into minute detail as to the character of the building and leaves very little of the design to be determined by the railway company's architects

apart. The side windows shall not be less than 9 ft. high and not less than 4 ft. wide. Windows shall be in three sections and each section shall be equipped with pivot and opening device. The buildings shall be equipped with side and end doors. The end doors shall be not less than 6 ft. wide and 15 ft. high, and there shall be two such doors for each track covered by the building. The side doors shall be the same width and height as the end doors and shall be not to exceed 40 ft. apart. The roof shall be provided with a cupola the entire length of the building and be equipped with side windows of not less than 3 ft. in width and 6 ft. in height, having pivot and opening device that shall be at all times operative. A similar cupola shall be provided for each two additional tracks in width of such building.

"The buildings shall be equipped with necessary heating

Car Repair Shed Designed by Northern Pacific to Meet Requirements of Minnesota Law

or engineers. The specifications as given in the statute are as follows:

"In buildings that cover more than one track the distance between the inside rails of each track shall not be less than 12 ft. Between the walls of the building and the outside rails there shall be a distance of 10 ft. The building or buildings shall not be less than 20 ft. high at the eaves. Each building shall be enclosed from roof to ground and shall have glass windows on each side not to exceed 12 ft.

facilities and shall at all times have drainage that will keep them in a clean and sanitary condition. They shall be equipped with sanitary drinking fountains where clean, wholesome drinking water can be obtained. A sufficient number of sanitary lavatories shall be provided for said employees. Such toilets shall be properly partitioned and there shall be at least one for each 15 persons employed. All scaffolding used in such buildings shall be made of clear lumber free of all knots and shall be kept in first-class

condition at all times. The use of paint spraying machines shall not be permitted inside such buildings."

The execution of the law is imposed on the Railroad & Warehouse Commission of Minnesota, which shall determine as soon as practical where and what buildings are to be built by the railroads and issue orders accordingly. Penalty for failure to comply with the provisions of the statute is a fine of not less than \$100 or more than \$500 for each offense, and each day or part of the day that failure continues constitutes a separate offense.

The manner in which railroads are complying with these statutes is indicated by the drawing of a structure designed by the Northern Pacific for construction at Watertown, N. D. This is a frame shed, 100 ft. by 250 ft., supported by 10-in. by 12-in. posts and spaced 20 ft. center to center transversely, and 21 ft. longitudinally. The roof consists of 2-in. by 8-in. planks carried on 4-in. by 12-in. purlines and covered with pitch and gravel roofing. The walls are composed of a layer of 1-in. by 8-in. shiplap covered by 1-in. by 6-in. drop-siding with tarred paper between. The foundations are of concrete and the floor of cinders. Tracks are provided at 20-ft. centers. The monitor is 21 ft. wide by 9 ft. high and is equipped with corrugated iron curtain walls at intervals of about 62 ft. as barriers to spreading fires. Toilet facilities are provided in a lean-to 18 ft. by 22 ft. in the middle of one side.

AIR PRESSES DESIGNED FOR CAR SHOP AND RECLAMATION WORK

BY F. S. TINDER
Material Inspector, Virginian Railway

Two air presses built for the reclamation department and car smith shop of the Virginian Railway have proved of considerable value in facilitating both reclamation and repair work, and their use has resulted in important savings of material and money. The double action press illustrated in Fig. 1 was developed for use in the reclamation department and has been kept busy straightening bent shanks and re-setting guard arms of car couplers, straightening angle and channel iron, flanged sheets for pressed steel cars, and other

Fig. 1—Double Action Air Press for Reclamation Work

miscellaneous work. It is also used to great advantage in straightening and re-flanging pressed steel car parts, as this material is best straightened cold. By the use of suitable dies on this machine, such miscellaneous articles as truss rods for brake beams, corner angles, sill steps, etc., can be formed and bent.

The machine is built mostly of second-hand material, the 15-in. I-beams used for the frame being removed from old bridges. Second-hand 14-in. by 12-in. air brake cylinders were used, two of these cylinders being bolted together and rebored for each side of the press. As indicated in the illus-

tration, a guide and crosshead is provided for the piston and through the operation of suitable levers, the plunger is forced down against a cast iron table on which the work is placed. The entire framework of the press is substantial and rigidly connected. The plunger is held in a vertical position by a supporting guide made of 4-in. heavy pipe, rigidly held in place. It is possible to obtain a working pressure of approximately 50 tons with this press.

The air press developed for blacksmith shop use, shown in Fig. 2, is built of the same material as the double action press previously described. The construction and operation of this press is quite plainly indicated in the sketch and will develop practically one-half the pressure of the double ac-

Fig. 2—Single Action Air Press for Car Shop Work

tion press. An additional advantage, however, consists in the fact that one side is open. This makes it possible to handle large sheets and odd shaped material. The press is used for straightening and forming various car parts.

The valve operating both of these air presses consists of an operating seat and stem used with the top case of an H-6 Westinghouse brake valve, the two important positions of the handle being application and release. The ordinary designs of air presses with a large cylinder acting directly on the ram are not only wasteful of air but also make it difficult to use sledges for straightening sheets while held in the press. These presses are economical in operation, easy to make and will be found important adjuncts to facilitate work in both the reclamation department and car blacksmith shops.

HOW AN ENGINEER GOT RICH.—We have just learned of an engineer who started poor 20 years ago and has retired with the comfortable fortune of \$50,000. This money was acquired through industry, economy, conscientious efforts to give full value, indomitable perseverance and the death of an uncle who left the engineer \$49,999.50.—*Official Bulletin, Colorado Society of Engineers.*

HEAT TREATMENT OILS.—The essential requirements of tempering oils are: flash and fire tests high enough to avoid serious evaporation loss or to incur high fire risk, comparative freedom from decomposition, absence of acid or acid forming substances, which would have a materially corrosive action on metals at high temperature, a fairly high heat capacity, and enough fluidity to permit rapid carrying-away of the heat.—*The Atlantic Lubricator.*

The Freight Car Shop at Elizabethport

CAR REPAIRS AT ELIZABETHPORT SHOPS

Interesting Features of the Work Done at the Principal Plant on the Central Railroad of New Jersey

THE Elizabethport shops of the Central Railroad of New Jersey are the largest car shops of that road, having a capacity of about 4,000 cars a month. The great variety of work done at this plant involves some interesting and novel practices. The account which follows is intended not as a comprehensive description of the shop practices,

Bracing Applied to Corners of Box Cars

but rather as a few notes on methods used for facilitating the work, for eliminating maintenance troubles and for securing improved service from the equipment.

Reinforcing Wooden Cars

In cars with wooden superstructure it has been found that the weaving of the body loosens the sheathing and lining and causes the car to leak. This action is particularly noticeable near the ends, and to overcome it the corners of cars passing through the shops are being strengthened by the application of diagonal braces. These braces, as shown in the illustration, are made of 4-in. by 1-in. channels, or of 3-in. by $\frac{3}{8}$ -in. bars, with an angle of $\frac{1}{4}$ -in. plate riveted to each

end. One brace is used in each of the four corners, being bolted to the side plate and the end plate.

On some of the wooden box cars of 60,000 lb. capacity steel center sills are being applied in connection with transom draft gear and friction springs. The center sill reinforcing consists of 9-in., 15-lb. channels, spaced $9\frac{1}{2}$ -in. back to back, with the flanges extending over the wooden center sills, to which the channels are bolted every two feet. Stop plates are riveted between the channels and to these in turn are fastened the bolsters. In order to give additional strength to the section of the center sill between the bolsters the two sills are tied together with $\frac{3}{4}$ -in. bolts and 1-in. pipe thimbles. The end sill is reinforced by a 10-in. channel.

Reinforcing Center Sills on Coal Cars

Hopper cars used for coal traffic often give trouble due to the center sills buckling a short distance beyond the bolster. The cause of such failures is usually excessive corrosion of the sills resulting from the moisture that drips upon

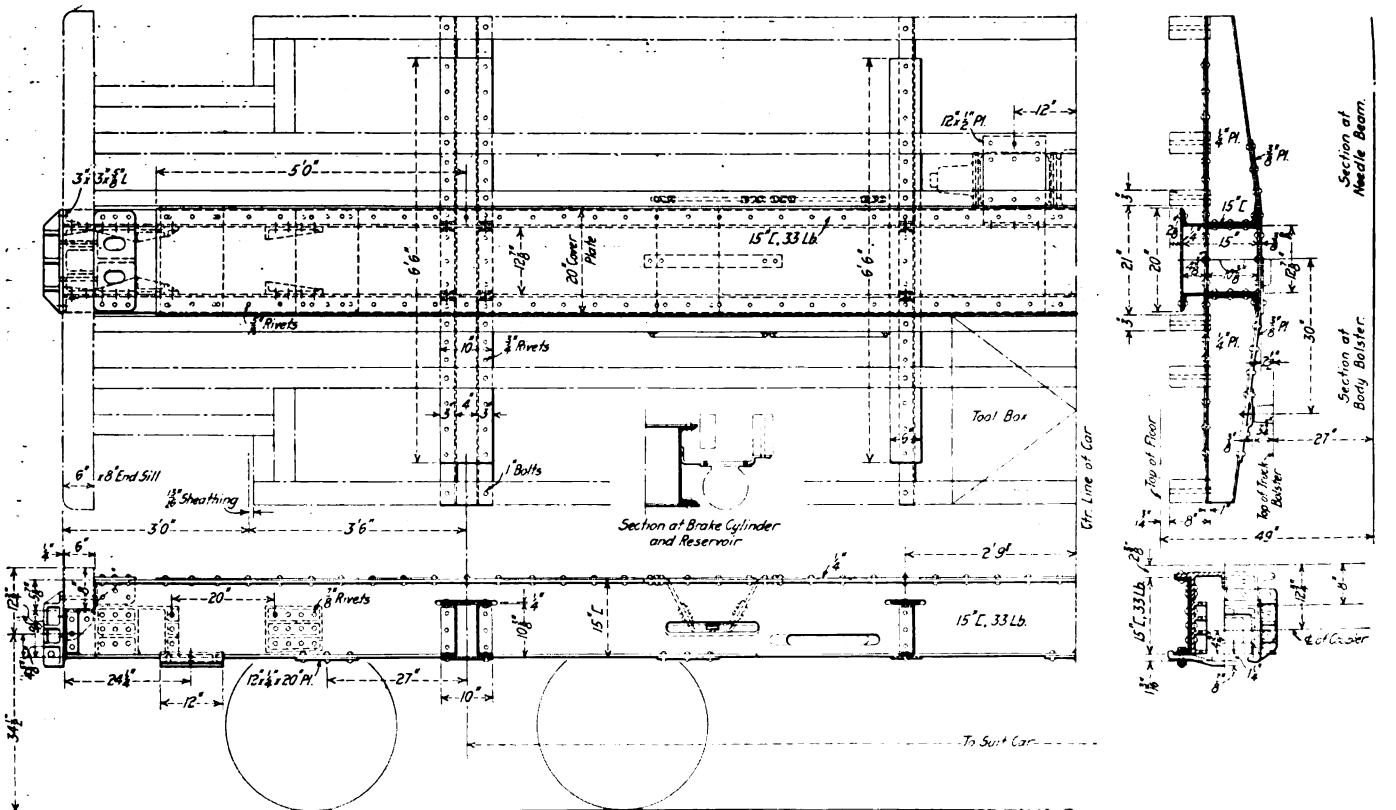

Reinforcing for Hopper Car Center Sills

them at this point. It is difficult to protect the sills from the water, which often contains sulphuric acid from the coal. Failure of the center sill is very costly to repair and to avoid such trouble the underframes on some classes of hopper cars have been reinforced at the points where they pass through

Reinforcing for 60,000-lb. Capacity Box Cars

Steel Underframe Applied to Caboose Cars

the hopper. This reinforcing consists of $\frac{3}{8}$ -in. plates, 5 ft. $7\frac{1}{2}$ in. long, flanged to fit between the flanges of the center sill channels as shown in the drawing.

Steel Underframes for Caboose

In order to make wooden cabooses suitable for modern service, the Central Railroad of New Jersey is fitting this

Bracket for Inside Hung Brake Beams Riveted to Arch Bar

class of equipment with steel underframes which are constructed at Elizabethport shop. The details of the underframes have been standardized. The center sills are made up of two 15-in., 35-lb. channels, continuous from end to

Details of the Brake Hanger Bracket

end. The center line of draft is $4\frac{5}{8}$ -in. from the lower flanges and the upper flanges and web plates are notched to receive the 6-in. by 8-in. end sill, which fits between the striking plate and a filler casting. A cover plate $\frac{1}{4}$ -in. thick and 20 in. wide extends 5 ft. beyond the bolsters.

The body bolsters are of channel section, pressed from $\frac{1}{4}$ -in. steel plate. Pressed steel fillers are also used between the center sills at the bolsters. The web plates are spaced four

inches apart and fit against the lower flange of the center sill. The top cover plate 10-in. wide, $\frac{1}{4}$ -in. thick and 6-ft. 6-in. long, passes through slots cut in the sills. The bottom cover plate is $\frac{3}{8}$ -in. by 10-in. by 6-ft. 6-in. and extends under the body bolster. Cast steel center plates and pressed side bearings are used.

The needle beams have web plates of one pressed section identical with those used in the bolsters. The fillers between the channels are also the same. The top cover plates are $\frac{1}{4}$ -in. by 6-in. by 6-ft. 6-in., while the bottom plates are $\frac{3}{8}$ -in. by 6-in. by 4ft. 0-in. Cross braces are riveted to the bottom flange of the center sills at the center line of the car midway between the needle beams and bolster and 2-ft. 3-in. outside the bolster. These underframes are fitted to receive Miner A-18 friction draft gear.

A Simple Uncoupling Arrangement

The Central Railroad of New Jersey is now applying to a large number of cars a simple uncoupling arrangement of rugged design, which does away with chains and clevises. The end of the uncoupling lever is bent to form an elongated

Uncoupling Mechanism in Lock Set Position

gated eye. The link for attachment to the coupler lock is a simple piece made in the forging machine from $\frac{5}{8}$ -in. round stock. A half round head is formed on one end and the eye on the other end is bent partly shut. This eye is slipped through the opening in the uncoupling lever and is closed after the end is passed through the eye in the coupler lock. The freedom of action secured by this arrangement is clearly shown in the drawing.

Applying Inside Hung Brake Beams on Caboose Car Trucks

On some of the lighter arch bar trucks which do not warrant extensive remodeling, a simple method has been adopted for applying inside hung brake beams. A forged bracket to support the brake beam is riveted to the top arch bar, as shown in the photograph. This does away with the necessity for changing the column posts or even removing the column bolts. As the arch bar is in compression the rivet holes are not objectionable and the bracket gives additional strength.

Cleaning Passenger Trucks

The labor involved in cleaning passenger trucks has been greatly reduced by using a spray for removing the lye clean-

ing solution. Water alone would not give satisfactory results in washing off the compound. A combining nozzle was made in which the water is introduced into a jet of air, forming a heavy spray. This has sufficient force to clean

Details of Uncoupling Arrangement Showing Wide Range of Action

the lye from the parts. It is also used for washing down the sides of cars and by attaching it to a tank it can be employed for whitewashing.

Winch for Hauling Cars

Steel cars passing through Elizabethport shop and in need of general repainting are thoroughly sand blasted before the paint is applied. As the sand blast building is only 90 ft.

Hauling a Cut of Cars with the Electric Winch

long the cars must be pulled out at frequent intervals. To avoid tying up a switch engine for this work an electrically operated three-ton Sprague winch has been installed just outside the building. A block is also attached at the entrance to the paint shop and by means of a rope the cars can be hauled in either direction.

THERE IS JUST ONE WAY to force prices down under present conditions—that is for all of us to pitch in and produce so much of everything that at the same time prices can and must go down. Cut the cost and boost the supply and prices must drop. But as long as we go on cutting the supply and boosting the cost by loafing on our jobs, prices will hold their upward course.—*Saturday Evening Post.*

PNEUMATIC CLAMP FOR TRIPLE VALVES

BY T. H. BIRCH

Air Brake Foreman, Chicago, Milwaukee & St. Paul

Many triple valves come to the car shop for repairs and if only a few minutes can be saved on each valve the total saving of time in the course of a year will be considerable. One way in which this time has been saved at the Milwaukee shops of the Chicago, Milwaukee & St. Paul has been by the construction and installation of a device which clamps triple valves quickly and holds them during the operation of cleaning and repairing. Formerly an ordinary vise was used for this purpose, but the contour of the check valve case made it somewhat difficult to hold the valve firmly, and in addition the valve was not in the most convenient position for repair work.

Adapting the clamping principle of the triple valve test rack the device, illustrated, was made and proved very successful for this work. Referring to the illustration, the de-

Clamp for Holding Triple Valves While Being Repaired

vice which is of simple construction consists of a bracket A made of 5/8-in. iron, bent up at the end and bolted to the repair bench as shown. This bracket is stiffened by two rods and supports a K-1 slack adjuster cylinder B, as shown. This cylinder is operated by air through the operating valve C, and when the air is turned on clamping arms DD are moved in such a way as to hold the triple valve firmly against the bracket. When the cylinder piston starts to move the clamping arms approach the bracket and come together, being guided by the slots EE. The operation of the clamp will be evident from an inspection of the illustration.

For any car shop repairing a considerable number of valves, this triple valve clamp will more than pay for the cost of its construction by the saving in time effected by means of its use.

METRIC SYSTEM CONDEMNED.—In addition to the recent order of Secretary of War Baker directing the discontinuance of the use of the metric system, the Navy Department also, through prominent officers, has expressed its opposition to that system.

REFRIGERATOR CARS.—There are approximately 115,000 freight refrigerator cars and 1,650 express refrigerator cars in service at the present time. Thirty thousand of the freight cars are owned by private car lines, while 250 of the express refrigerator cars are owned by the American Railway Express.

THE INSPECTION OF FREIGHT EQUIPMENT*

Handling and Testing Tank Cars; Regulations Governing Interchange; Billing for Foreign Repairs

BY L. K. SILLCOX

Assistant General Superintendent Motive Power, Chicago, Milwaukee & St. Paul

THE rules of the American Railroad Association, Mechanical Section, cover Standard Specifications for Tank Cars and schedules for testing tanks and tank safety valves. Extracts from sections of the rules relating to the handling of this equipment are given below.

Transportation requirements. (c) A tank which does not meet the prescribed tests shall be withdrawn from transportation service.

Tests

22. *Certification of Tests:* Tests of all tanks and their safety valves shall be certified by the party making the tests to the owner of the tank car and to the Chief Inspector, Bureau of Explosives, in the form prescribed by the bureau.

23. *Tests of Tanks.* CLASS I. Tanks shall be tested at intervals of not over five years.

CLASSES II AND III. Tanks shall be tested before being put into service, again at the expiration of ten years, and after that at intervals of not over five years; with the exception that where tanks are used for the transportation of such corrosive products that deterioration is to be expected in a shorter time, the first test for such tanks shall be reduced to five years. Tanks requiring this five year test shall be those used for the transportation of chemicals such as acids, ammonia, liquors, etc., and such other products as may hereafter be specified.

CLASS IV. Tanks shall be tested before being put into service, and after that at intervals of not over five years.

CLASS V. Tanks shall be tested before being put into service, and after that at intervals of not over two years.

CLASSES I, II, III AND IV. Any tank damaged to the extent of requiring patching or renewal of one or more sheets, or extensive riveting or recalking of seams, shall be retested before being returned to service.

CLASS V. Any tank damaged to the extent of requiring patching or renewal of one or more sheets shall be retested before being returned to service.

Tanks shall be tested to the following pressures:

Class I	Either 40 or 60 lb. per sq. in.
Class II	Either 40 or 60 lb. per sq. in.
Class III	60 lb. per sq. in.
Class IV	75 lb. per sq. in.
Class V	300 lb. per sq. in.

CLASSES I, II, III and IV. All tests shall be made by completely filling the tank with water, or other approved liquid safe to use, of a temperature which shall not exceed 70 deg. F. during the tests, and apply the pressure in any suitable manner. The tank shall hold the prescribed pressure for not less than ten minutes without leak or evidence of distress after the tank has been calked tight.

CLASS V. The tank shall hold the prescribed pressure for not less than 30 minutes without any leak whatever. Calking to stop leaks developed during the test will not be permitted.

ALL CLASSES. When tanks are tested, the date, pressure to which tested, place where test was made, and by whom, shall be stencilled on the tank in accordance with the Master Car Builders' standard marking for freight cars.

24. *Test of Safety Valves.* CLASSES I, II, III and IV. Safety valves shall be tested at intervals of not over two years, those on new cars being tested before the cars are placed in service.

CLASS IV. At intervals of not over six months.

CLASSES I, II, III and IV. The test may be made without the removal of the valve from the car, provided the valve unseats at a total pressure corresponding with the area of the seat multiplied by the required pressure.

ALL CLASSES. When valves are tested, the date, pressure to which tested, place where test was made, and by whom, shall be stencilled on the tank in accordance with Master Car Builders' standard marking for freight cars.

20. The pressure to which valves shall be set are prescribed in Section 20 of each specification and are:

CLASSES I and II. Products with flash point below 20 deg. F., valves shall be set at 25 lb. per sq. in. Products

*Seventh of a series of articles on this subject by Mr. Sillcox, copyright 1920 by the Simmonds-Boardman Publishing Co.

with flash point 20 deg. to 150 deg. F., valves may be set to 12 lb. per sq. in.

CLASS III. Valves shall be set at 25 lb.

CLASS IV. Valves shall be set at 25 lb.

CLASS V. Valves shall be set at 200 lb.

The tolerance above or below the specified pressure is one pound for the 12-lb. setting; three pounds for the 25-lb. setting and five pounds for the 200-lb. setting.

Apparatus for setting safety valves in place on cars should be furnished at the principal repair points. These devices should be made up in accordance with the specification for tank cars, a copy of which must be in the hands of each car foreman.

Interstate Commerce Commission Tank Car Regulations

1822, (g) Tests of all tank cars and their safety valves, as made in compliance with Master Car Builders' rules, must be certified by the party making the tests to the owner of the tank car and to the chief inspector, Bureau of Explosives; and this certification must show the initials and number of the tank car, the service for which it is suitable, the date of test, place of test and by whom made.

1824, (j) After May 1, 1915, a tank car must not be used for shipping inflammable liquids with flash point lower than 20 deg. F., unless it has been tested with cold water of 60 lb. per sq. in. pressure and stencilled as required by Master Car Builders' rules.

Note. For casinghead gasoline, blended or unblended with other products, and with vapor tension not exceeding 10 lb., tank cars, 60 lb. test class, must have safety valves set to operate at 25 lb. per sq. in., and provided with "fool proof" dome covers (see amended paragraph 1824 (k), effective May 15, 1916).

For all other liquids with flash points lower than 20 deg. F., safety valves must be set to operate at 25 lb. and "fool proof" dome covers must be provided not later than July 1, 1917 (see amended paragraph 1825 (k), effective July 1, 1917).

The above instructions are taken from the Standard Specification for tank cars. It is important that each car foreman familiarize himself with the specification for tank cars, and especially the instructions pertaining to the testing of tanks and the safety valves. As stated above, certain points should be equipped with the apparatus for testing valves on cars, the object being to equip only the more important interchange points, so that cars can be tested before being delivered in interchange, when the date of the last test requires that retest be made. All points having equipment to test safety valves should make the report on B. E. form 17-B, Certification of Test, to cover each car tested.

Leaky Tank Cars.—In cases where tank cars are transferred due to leakage and no repairs made, they should be stencilled on each side "Leaky tank; do not load until repaired."

Outlet Valves and Dome Caps on Tank Cars

Tank cars enroute should never be allowed to proceed with tank outlet valve caps dangling from retaining chains, since they break off and are lost in this manner. In some instances, employees have been found opening outlet valves on the bottom of empty tank cars which have been loaded with gasoline or other oils, to drain them. This is a very dangerous practice and should not be permitted. In the same manner dome caps are to be properly secured and in place at all times.

Hooks for Refrigerator Car Doors

Refrigerator cars not equipped with door hooks and fasteners to secure the doors in an open position will not be accepted in interchange.

Stake Pockets for Flat Cars

It is desirable and necessary for flat cars used in commercial service to have side stake pockets spaced 24 in. minimum and 42 in. maximum. System cars are to be

equipped as fast as possible with bent plate type stake pockets secured by either bolts or rivets and inside washer bearing plate.

Temporary Running Boards

When it is necessary to provide temporary running boards and hand rails to well-hole cars and those not equipped with roofs or running boards to make the equipment safe for trainmen, the cost is chargeable to the owner in cases where owners are responsible for the defective condition. The cost of applying temporary hand railings to, or boarding over the openings on empty well-hole cars, is also chargeable to the car owner.

General Handling of Interchange

If a car has defects for which the owners are not responsible, the receiving line shall require that a defect card be securely attached to the car. Defect cards shall not be required for any damage so slight that no repairs are required, nor for raked or cornered sheathing, roof boards, fascia, or bent or cornered end sills, not necessitating the shopping of the car.

At outlying points where joint inspection is not in effect, the matter will be left to the judgment of the receiving line. Where chief joint interchange inspectors are employed, the decision will be made by the chief interchange inspector.

Defect cards shall not be required for missing material in fair usage from cars offered in interchange. Neither shall they be required of the delivering company for improper repairs that were not made by it.

Defect cards must be of the form prescribed by standard instructions. They must be of cardboard, printed in red ink on both sides, and must be filled in on both sides with ink or black indelible pencil. The cards must plainly specify in full each item for which charges are authorized, indicating the location of defects.

To justify bill, repairs authorized by defect cards must be made within two years from date of first receipt of car on home line, except wrong repairs, which must be corrected within nine months from date of first receipt of car on home line.

Any road making partial repairs of defects on a car which are covered by a defect card will have the defects repaired crossed off the original card with ink or indelible pencil and the card replaced on the car. A copy of the card accompanying the bill with the defects which were not repaired crossed off will be sufficient authority to bill.

Original Record of Repairs

When repairs are made to a foreign car (except as otherwise provided) or to any car on the authority of a defect card, a form shall be used for the original record of repairs, from which the billing repair card shall be made. This form embodies the minimum information required for the proper preparation of billing repair cards. Additions may be made to this form and its size made to suit the requirements of any company. This original record of repairs may be in book form if so desired.

A card similar to the above in its essential requirements, upon which repairs to more than one car may be recorded, may be used for recording minor repairs made in transportation yards.

In recording repairs upon the original record the following requirements must be observed:

(1) Cars shopped for repairs must be carefully inspected by an authorized person before the work of repairing is begun, and all work authorized by him must be entered upon the original record, including the location of each item of repairs and the exact reason or cause for making repairs. This information must not be assumed, but must be deter-

mined by an actual inspection. The common terms "broken," "bent," "missing," etc., if used, when caused by wreck, derailment, cornering, sideswiping or other causes must be qualified to show such cause.

(2) Special care must be taken to obtain a correct account of the material actually used. The finished sizes of lumber as applied to the car must be shown on the original record; feet, board measure need not be shown. The number and size of bolts, and the purpose for which they are used, must be shown upon the original record; the weights need not be shown. Nuts must be specified, except those used on bolts renewed, in which case an average of one nut per bolt will be assumed as used, regardless of whether double nuts are used.

The actual weight of forgings, structural or pressed steel shapes and weight and kind of castings must be shown on the original record in the space provided, except where the weight is accurately determined by definite description. Paint and nails must be shown on the original record; the quantity need not be shown in those cases where it can be properly determined by the billing clerks.

(3) All items carrying labor charges must be covered in proper detail on the original record; the time or money charges need not be shown. For items of labor computed on the rivet basis, the number and diameter of rivets must be shown on the original record. For items of labor for straightening or repairing, computed upon the weight basis, the weight of material must be shown on the original record.

(4) The original record must be signed by the authorized person making the original inspection and the person making the complete inspection or by other authorized person making the original record, to vouch for its correctness. The original records covering minor repairs made in transportation yards must be signed by either the person inspecting the repairs or the workman who repairs the car. All corrections made on the original record must be made by the person or persons who have vouched for the correctness of the original record by their signature.

Billing Work on Foreign Cars

These original records must be kept on file, for ready reference, preferably either at the point where repairs are made or the point at which they may be stored in accordance with local regulations. The billing repair cards must check with the original record of repairs, in so far as they should properly check as regards to details charges.

When repairs of any kind are made to foreign cars a billing repair card must be furnished the car owner, except as otherwise provided. This card must specify fully the repairs made, the reason for same, the date and place where made and the name of the road making repairs, and must also show the location of parts repaired or renewed.

When repairs are made to any car on authority of a defect card issued by other than the owner of the car, in addition to the billing repair card furnished the car owner, a separate billing repair card must accompany the defect card. This separate billing repair card must show the repairs made, details of charges, date and place where repairs were made; also references to the name or initial of the road issuing the defect card and the date issued.

If no bill is to be rendered, the billing repair card must be attached to the monthly bill, with the words "no bill" written across the face of the card, in which case the cards must be entered in the billing statement in the first four columns, with the notation "no bill" in the fifth column for reference.

The billing repair card shall be made in duplicate, the original to be known as the billing repair card and the duplicate to be known as the record repair card and to be of the forms prescribed, all items of repairs to be in handwriting or typewriting.

The following information must be specified on billing repair cards:

MCB couplers or parts thereof, R and R.....	{ New or second hand. Size of shank. Where 1 1/4 in. head coupler or type D coupler is removed or applied, it must be so stated. Riveted yoke or key attachment. Cast steel, cast iron, wrought steel or steel tired wheels. New or second hand. Cause of removal (See MCB rule 10).
Wheels and axles, R and R.....	{ MCB or non-MCB, length of axle, diameter and length of journal, diameter of wheel fit, diameter of center of axle. (Only one dimension for length of journal, diameter of journal or diameter of wheel fit to be given, which shall be the dimension nearest the condemning limit.) All markings on wheels and axles; if no marks are found, a notation to that effect must be made. Box number (See MCB rule 14). New or second hand (relined journal bearings are considered as new).
Journal Bearings.....	{ Solid filled or other kind R & R. Make or name. Length of journal. Box number (See MCB rule 14).
Brake shoes, applied.....	{ New or second hand. Cast or reinforced back.
Metal brake beams, R & R.....	{ New or second-hand applied, if MCB, and number of same, or non-MCB. Make or name. Cause of removal.
Triple valve, R & R.....	{ Make and type. When cleaned, must show "tested, per Rule 60" (when so tested), to justify charge.
Air hose applied.....	{ New or second-hand.
General	{ Finished sizes of lumber. Feet of lumber. Value of miscellaneous items. Hours of labor. (The above information to be shown opposite each item, except where no bill is rendered.)

When lead paint is used, it must be so specified.

When triple valve, cylinder or centrifugal dirt collector is cleaned, the initial of road and date of last previous cleaning must be shown.

If necessary to remove the load to make repairs, as specified, it must be plainly stated.

When tank or safety valve of tank cars are tested in accordance with the MCB specifications for tank cars, the certificate of test as required by the Interstate Commerce Commission regulations must accompany the billing repair card.

Interpretations Regarding Billing

Q.—Is it necessary to show the dimension for over-all length of axle, in addition to showing whether MCB or non-MCB length?

A.—No, the over-all dimension need not be shown.

Q.—Is it necessary to show how much of the flange, tread, rim, etc., is defective on wheels removed? Is the term "worn flange" or "chipped flange" sufficient without showing how thick the flange is when removed or how long the chip is?

A.—For cast iron or cast steel wheels it is unnecessary to show any dimensions or qualify the terms in any way, as it is assumed that the repairing line would not remove the wheels unless the defects were beyond the limit of safety. In so far as wrought steel wheels are concerned, it is necessary to furnish the information specified. In noting the cause of removal of wheels and axle, standard terms shall be used. In all cases of wrought steel wheels, the actual thickness of tread must be shown before and after turning off, measured from the base line of the tread to the condemning limit of the tread, which is 1/4 in. above the witness groove; also show the actual thickness of tread on other wheels ap-

plied. This information must be reported to car owners regardless of whether or not repairs are chargeable to the owners.

Journal bearings having a babbitt lining $\frac{3}{8}$ in. thick or thicker shall be charged as filled journal bearings, and not as solid journal bearings.

The evidence of a joint inspector, or the joint evidence of two inspectors, one representing the owner of the car and the other representing a railroad company, subscriber to the MCB rules, that the repairs are not proper, shall be final; the evidence to be signed only after an actual inspection has been made.

A joint evidence card should be used for this purpose, which shall describe and show the location of parts repaired or renewed. This card shall be of the form prescribed. If repairs are not corrected at the time of inspection, the joint evidence card shall be attached to the car. Joint evidence must be obtained within ninety days after first receipt of car home. The joint evidence may be obtained at any point on the home line at which the improper repairs are found, but preferably at the point where the car is received, and only after an actual inspection is made.

The joint evidence card showing copy of billing repair card covering wrong repairs, when wrong repairs have been corrected, shall be sent to the company issuing such billing repair card. If within 60 days from the date of such request the latter does not issue its MCB defect card covering, bill made on copy of joint evidence and copy of billing repair card shall be final authority, provided the wrong repairs mentioned on joint evidence card are covered by such billing repair card. It must be stated on back of joint evidence card where and when the wrong repairs were corrected.

The end of car toward which the cylinder push rod travels shall be known as the *B* end and the opposite end shall be known as the *A* end.

Facing the *B* end of the car, in their order on the right side of the car, wheels, journal boxes and contained parts, shall be known as *R-1*, *R-2*, *R-C*, and *R-3*, and similarly those on the left side of car shall be known as *L-1*, *L-2*, *L-3* and *L-4*.

Defect cards and joint evidence cards must be securely attached to the car with at least four tacks, preferably on the outside face of an intermediate sill between cross-tie timbers on wooden cars, and on steel cars to a cardboard located either on a cross tie under the car or on the inside of the sill at the end of the car.

Duplicate defect, billing repair or joint evidence cards must be furnished promptly, on request, for lost or illegible cards.

Any car having defects which render it unsafe to run, unsafe to trainmen, or to any lading suitable to the car, may be repaired.

Repairs to foreign cars shall be promptly made, and the work shall conform in detail to the original construction, and with the quality of material originally used.

Standards for Repairing Foreign Cars

In repairing foreign cars:

(a) Defective non-MCB standards may be replaced with MCB standards (which must comply with MCB specifications), provided such substitution does not impair the strength of the car. Any increased cost resulting from and any expense of alteration necessary for the application of such MCB standards shall be charged to the car owner. Scrap credits are to be allowed for undamaged parts thus removed.

(b) Malleable iron, wrought iron or steel MCB standards may be substituted for each other or for gray iron MCB standards, gray iron MCB standards applied in lieu of malleable iron, wrought iron or steel MCB standards shall be considered as wrong repairs.

(c) In replacing MCB standard couplers, MCB type D Couplers or MCB temporary standard couplers, the dimensions of shank and butt of MCB couplers standard to the car must be maintained, except that $9\frac{1}{2}$ in. butt may be substituted for $6\frac{1}{2}$ in. butt when used with MCB standard yoke in substitution for non-MCB standard yoke.

(d) If the car owner elects, on account of improper repairs, to remove an MCB standard coupler, MCB type D coupler or MCB temporary standard coupler in good condition, second hand credit should be allowed, and charge be confined to second hand coupler applied.

(e) MCB No. 2 brake beams may be used in repairs to all freight equipment cars equipped with MCB No. 2, MCB No. 1 or non-MCB brake beams. Any increased cost resulting from the application of No. 2 brake beams to be borne by the car owner. MCB No. 3 brake beams must be replaced in kind.

(f) The billing repair card must specify the kind of material applied and removed, and the bill rendered in accordance therewith.

(g) Cast-iron brake shoes may be replaced with brake shoes having a reinforced back and the increased cost charged to the party responsible for the repairs.

(h) White pine, yellow pine, fir or cypress may be used when repairing siding, when of equal grade or quality to the material standard to the car. Fir, oak or southern pine may be substituted for each other in the renewing or splicing of longitudinal sills and side plates. Oak and southern pine may be substituted for each other in renewing end plates. Fir and southern pine may be substituted for each other in renewing or splicing end plank and side plank.

(i) Brake shafts, sill steps, uncoupling levers and grab irons must not be welded.

Cotter keys are not to be applied to knuckle pins of couplers on cars other than hopper and fixed-end gondolas.

Interpretations—Q.—Does the substitution of a New York auxiliary reservoir and cylinder in place of a Westinghouse constitute wrong repairs?

A.—The substitution is permissible, inasmuch as these details are interchangeable and are of the same dimensions, and the substitution of one for the other is not wrong repairs.

Q.—We are having trouble in living up to the Interstate Commerce Commission rules regarding end ladder clearance, due to the fact that some railroads do not replace our couplers with those of the latest dimensions, namely, $9\frac{1}{4}$ in. from inside face of knuckle to striking face of coupler horn. What protection is offered under the rules?

A.—That end ladder clearance may be maintained, couplers of less than $9\frac{1}{4}$ in. from inside face of knuckle to striking face of coupler horn should not be applied in repairing foreign cars. This should not be construed to mean that a coupler with $9\frac{1}{4}$ in. dimensions may be submitted for the MCB temporary standard coupler or the MCB standard Type D coupler.

Q.—Will it be necessary to stencil cars equipped with the D type of coupler in order to protect them against substitution of the present type of coupler?

A.—Yes.

Q.—Is it permissible to charge for cast steel bottom brake rods applied to foreign cars when wrought iron is standard to the car?

A.—Inasmuch as the association has a standard bottom connection, it is permissible to make use of cast steel in this connection. The charge should be on the basis of material applied and the credit on the basis of material removed.

Q.—Is it permissible to charge for cast steel when cast steel column castings are applied in place of malleable iron standard to the car?

A.—Cast steel may be substituted for malleable iron but the charge should be limited to the kind of material removed. The association has no standard column casting.

Q.—Is it proper in cases where a K-2 triple valve has been applied in place of a G.N.-2 triple valve to scrap the G.N.-2 valve, or should the charge be confined to a charge for cleaning?

A.—If the car was built prior to Jan. 1st, 1915, no charge for this betterment could be made, except upon authority of the car owner.

Q.—In connection with the interpretation of the 1916 code of rules regarding the substitution of Westinghouse triple valves for New York triple valves, or vice versa, what triple valves manufactured by the Westinghouse and New York air brake companies are considered as being of similar types?

A.—The MCB standard K-1 and K-2 triple valves, manufactured by both the Westinghouse and New York air brake companies are the only triple valves that can be properly considered of similar type.

Improper Repairs

Any company making improper repairs by using material which the repairing line should carry in stock is solely responsible to the owners. Such improper repairs must be corrected within nine months after first receipt of the car on the home line, to justify bill.

The company making such improper repairs must place upon the car, at the time and place the work is done, an MCB defect card, which card must state the wrong repairs made.

In order that repairs to cars may be expedited as fully as possible, foreign or private line cars may be repaired by the handling line by using material from their own stock instead of ordering material from the car owner, in which event the repairing line is absolved from all responsibility for the cost of standardizing repairs thus made.

Interpretation: Q.—In the event of using wrong material from stock, instead of ordering correct material from the car owner, are such repairs chargeable to the owner?

A.—Yes, provided the original defects are owners' responsibility.

Companies shall promptly furnish to each other, upon requisition, and forward, freight or express charges collect from point of shipment, material for repairs of their cars on foreign line. If the material is for repairs of car owner's defects, the foreign company may bill the car owner for the entire freight charges, and in such case the car owner may reclaim freight charges for the portion of the movement over its own line. If the material is for repairs of user's defects, the foreign line may reclaim only for that portion or the movement over its line. A separate bill, with copy of freight, express or due bill attached, should be rendered for the freight or express charges, showing reference to the bill covering repairs.

Requisitions for such material shall specify that it is for repairs of cars, giving the number and initial of such car, together with pattern number, sketch or other data to enable correct filling of the requisition. Material weighing less than 250 lb. gross weight ordered from the car owner must be shipped by express.

The company having the car in its possession at the time shall provide from its own stock the following: Lumber, forgings, hardware stock, paint, hairfelt, piping, air brake material and all MCB standard material.

Interpretations: (1) Q.—If material is shipped by local freight to repair owner's defects, who should pay the cartage from the freight depot to the repair tracks?

A.—There should be no charge for cartage.

Q.—(2) What items are covered by the word "forging"?

A.—Commercial shapes, such as channels, Z-bars, etc.,

should be furnished by the repairing line. Pressed steel shapes which require special dies for their forming should not be carried as forgings; such material should be furnished by the car owner.

On May 14, 1919, the American Railroad Association Section 111—Mechanical—issued circular No. S-111-37, making certain changes in the rules of interchange. The changes again make car owners responsible for and therefore chargeable with, the following items of repairs, which prior to April 15, 1919 were not to be billed for.

1. Air hose gaskets, applied, except with hose complete, applied.
2. Bolts, 6 in. long or under, applied, except when used to complete items of repairs not herein listed.
3. Brake beam finger guard pins, finger guard pin castings, safety chain clips, safety chains, links or hook bolts, applied.
4. Brake hangers, repaired or applied, except with renewal or change of brake beam.
5. Brake hanger pins or bolts, applied.
6. Brake pawl, applied.
7. Brake pins or key bolts, applied.
8. Brake ratchet wheel keys, applied.
9. Brake shaft rings, applied.
10. Brake shoes, applied.
11. Brake shoe keys, applied.
12. Carrier iron, Bettendorf type, when turned over, no charge for adjustment.
13. Coupler release clevises, clevis rings or chains, clevis pins or bolts, applied.
14. Door hasps and staples, applied, except with complete door, applied.
15. Door seal pins or chains, applied, except with complete door, applied.
16. Journal box lids and bolts, or springs for same, applied.
17. Knuckle locks, applied, except with coupler, complete, applied.
18. Knuckle lock sets, applied, except with coupler complete, applied.
19. Knuckle pins, applied, except with coupler complete, applied.
20. Lag screws, applied, except when used to complete other items of repairs not herein listed.
21. Nuts or lag screws tightened.
22. Nuts, applied, except those used in renewing bolts, other than bolts 6 in. long or under, where the latter are used in completing items of repairs not herein listed.
23. Nut locks, or lock nuts, applied.
24. Pipe fittings, union gaskets, pipe hangers, clamps, and cutting of pipe threads, except with renewal of any or all air brake on retaining valve pipe.
25. Refrigerator car door hooks, applied.
26. Rehanging side or end doors.
27. Release lever brackets, applied.
28. Release valve rods, repaired or applied.
29. Renailing sheathing, lining, fascia or roofing.
30. Spring cotters and split keys, applied.
31. Straightening brake shafts and uncoupling levers when not removed from car.
32. Staples, applied.
33. Wood screws, applied, except when used in renewal of running board.
34. Washers, applied.

The circular also provides that defect cards shall be required as between all roads for cars having defects for which the delivering line is held responsible under MCB rules.

Defect cards shall also be required as between all roads for improper repairs made to cars as per MCB rules 12 and 13.

Delivering lines again become responsible to the receiving line for the cost of transferring or adjusting lading on cars as per MCB rule 2 and A.R.A. rule 15.

This circular also abrogated modifications A, B and C of the Interchange Rules governing passenger train cars, so that defect cards are again required for delivering line defects on cars offered in interchange, also wrong repairs made to foreign cars. Gas certificates must be issued to the delivering line to cover gas in holders of cars received and when passenger cars leave the road a gas certificate must be requested from the road receiving the car.

Interchange at Chicago

At Chicago, the handling of cars in interchange will be in accordance with the Chicago Car Interchange Bureau's instructions, a copy of which follows:

In accordance with American Railroad Association, Section III Mechanical Circular No. S-111-37 dated May 14th, 1919, effective June 1st, 1919, the cost of transferring the lading of freight cars or re-arrangement of lading at junction points in the Chicago Switching District, including the main line of the E.J. & E. from Waukegan, Ill. to Porter, Ind. shall be handled as follows:

FIRST: The delivering line shall pay cost of transfer or re-arrangement:

(a) When transfer is due to defective equipment that is not

safe to run according to MCB rules, *except where the repairs can be made under load as per MCB rule 2.*

(b) When transfer or arrangement of load is due to contents being improperly loaded or overloaded, according to MCB rules, or the Interstate Commerce Commission regulations for the Transportation of Explosives and other dangerous articles by freight and by express, or when dimensions of the lading of open cars are in excess of the published clearances of any of the roads covered by the routing.

(c) When transfer is due to the delivering line not desiring its equipment to go beyond junction points.

(d) When cars cannot pass the approved clearances of the American Railroad Association.

SECOND: The receiving road shall pay the cost of transfer or re-arrangement:

(e) When cars cannot pass clearances, except as provided in paragraph (d), or when cars and lading exceed load limit or cannot be moved through on account of any other disability of the receiving line.

(f) When receiving road desires transfer to save cost of mileage or per diem.

THIRD: Transfer orders shall not be issued against belt or intermediate switching lines, except:

(g) For defective or improperly loaded cars when load originates on their rails.

(h) For defects which develop after receipt from trunk lines, providing defects existing on receipt of car were not the cause of subsequent damage which necessitated transfer of car, or re-adjustment of lading.

(i) Cars delivered to belt or intermediate switching line with defects which would make transfer necessary either by the belt or intermediate switching line or their connection, if transferred by the latter, the belt or intermediate switching line is to be relieved of the cost of transfer, and transfer order issued against the trunk line delivering the car to the belt or intermediate switching line.

FOURTH: Seven dollars per load will be charged for such transfer or re-arrangement, except in cases of adjustment of lading and application of door protection in house cars, a charge of two dollars will be made.

FIFTH: All roads in the Chicago switching district, in so far as the transfer of loaded cars or the adjustment of lading is concerned, shall arrange as follows:

(1) Car foremen, inspectors and others will be required to fill in all information on form 159-A and must also show on same what disposition was made of the car after it has been transferred, showing to what shop the car was carded for repairs after transfer, or if it is a Chicago owned car it must be shown that the car was carded home to the car owners for repairs. In cases where cars are transferred for old defects, or the lading is readjusted due to the car being originally improperly loaded, the form should be made out in quadruplicate and in cases where the cars are transferred or lading readjusted due to new damage or the lading is adjusted due to rough handling, it should be made out in duplicate and forwarded to the chief interchange inspector, who will issue authority for transfer or adjustment of lading against the road responsible.

(2) No authorities for transfer will be furnished for cars having the following defects:

(a) Defective wheels and axles under all cars.

(b) All other truck defects on home cars.

(c) All other truck defects on foreign cars, except metal bolsters, center plates, where cast integral with bolsters, metal truck sides, metal truck transoms and metal spring planks, also excepting non-MCB standard journal boxes and contained parts in cases where the MCB standard is not a proper substitute.

(d) Defective outside wooden end sills on all cars.

(e) Defective body center plate and center plate bolts that do not pass through center sills on all cars, except when such center plates are cast integral with bolsters on foreign cars; also center pins that are not applied from inside of car on all cars.

(f) Renewal of roof boards of outside wooden roofs, and of inside metal roofs, where such renewal does not exceed 25 per cent of the roof boards, and where purlines, rafters, ridge pole, side and end plates are in good condition, on all cars.

(g) Missing or defective side doors (except that an adjustment order may be obtained to apply proper door protection, as required by the Loading Rules), end doors, roof doors and hatch covers on all cars.

SIXTH: The repairs to car or transfer of lading is to be done by the railroad having facilities nearest available. If facilities are equally available by both railroads, the car will be moved to facilities located in the direction car is moving.

SEVENTH: Bad order cars which previously had been delivered in bad order under load must be repaired by the road making transfer if they have facilities and material; if not, the nearest repair point on any line, having material and facilities should make repairs—with the exception of Chicago owned cars, which may be delivered to the car owners for repairs.

At Minneapolis and St. Paul the handling of cars in interchange will be in accordance with the Twin City Joint Inspection Association Bulletin which is similar to the Chicago regulations.

At Minneapolis and St. Paul the handling of cars in interchange will be in accordance with the Twin City Joint Inspection Association Bulletin which is similar to the Chicago regulations. At Council Bluffs and Omaha the handling of cars in interchange will be in accordance with an agreement which is practically the same as the Chicago agreement. At Kansas City the interchange of cars will be handled in accordance with an agreement which will also be practically the same as the Chicago agreement. At other interchange points the interchange of cars will be handled strictly in accordance with the MCB rules, unless there be some local agreement to the contrary.

FREIGHT CAR ROOF CONSTRUCTION*

BY H. R. NAYLOR

It is interesting to note the progress made on this continent in car roof construction from the time when the outer covering consisted only of a single layer of boards having tongue and grooved joints. In many instances, I believe it was customary to use a wood shingle roof similar to that commonly used in house construction. Another method adopted, presumably to overcome the leakage, was to apply the roof boards lengthwise of the car, overlapping each other similar to clapboarding on present-day wooden buildings. This method of construction proved unsatisfactory, and gave way to the double board roof which can be seen on a large number of cars even today. This was a decided improvement over the earlier types of roof, especially when at a later date a layer of waterproof paper was applied between the first and second course of boards, which became known as the "plastic roof." This roof undoubtedly protected the lading for some time, but it eventually became waterlogged, and a method was then sought to prevent the water leaking between the joints of the top course of boards which rapidly destroyed the paper and bottom boards. This was overcome to a great extent by grooving the face of the top boards, the grooves acting as drains, carrying off the water, and protecting the joints from possible leakage. In fact, this is the most common type of roof to be found on stock and refrigerator cars at the present time.

The Sub-Metal Roof

The next step was a distinctly new departure, and brought into existence the metal sub-roof, over which a wood roof was applied for protection only. The roof framing consisted of a ridgepole, carlines and purlins, to which an addition was made in the form of cross rafters. The galvanized metal sheets were formed with corrugations, and fitted into suitable grooves in the ridgepole and rafters, providing altogether a fairly effective watershed. But it was not long before the usual complaints were being made about this new metal roof, owing to the grooved edges of the wooden rafters breaking away, allowing the metal sheets to sag and leak. This defect was eventually overcome by flanging the roof sheets, and applying a metal capping over the rafters, which enclosed the flanges of the roof sheets, making a continuous metal water-

*From a paper presented at the Canadian Railway Club by Mr. Naylor, who is assistant works manager, car department, Canadian Pacific Railway.

shed for the full length of the car. With a few later modifications this was the final attempt along the lines of a metal sub-roof.

Some of the principal objections to the metal sub-roof are that the roof sheets in time buckle up at the eaves, and work out of the grooves in the ridgepole. With the constant twisting and straining of the car superstructure, the metal sheets and caps are soon displaced and bent, and in making repairs to the outer wood roof the metal sheets are frequently punctured by nails carelessly driven, all of which result in damage to the lading. The outer wood roof also requires frequent renewal, on account of constant exposure, which is a rather expensive item when added to the cost of maintaining the metal sub-roof.

The demand for improved roof construction was then met by adopting a roof framing made of steel, as in other parts of the car; for instance, the wooden carlines which were bolted to the sideplates, and a source of constant trouble, gave way to the steel carlines of various shapes, riveted to the sideplates, in order to give greater rigidity and strength. Other parts of the roof framing were improved and reinforced in a similar manner, providing greater stability, which is most essential if the outer roof is to be protected from the racking and straining of the car superstructure.

Outside Metal Roofs

The demand for greater stability was largely responsible for an entirely new departure in roof design, for instead of placing the wood roofboards on the outside, as in the case of the metal sub-roof, the plan was reversed, the roof boards being applied direct to the roof framing, and the metal roof sheets used as an outer protection for the boards in addition to acting as a watershed. The roof boards in this case being applied direct to the roof framing had the effect of bracing the roof against cornering and bulging, and brought into extensive use the outside metal roof.

The outside metal roof usually consists of one course of 13/16-inch tongued and grooved boards, securely fastened to the roof framing, the outer metal roof being formed of galvanized iron sheets generally of No. 22 gage. At the junctions of the main sheets suitable weather-proof protection is provided by metal caps, formed in various ways to interlock with the flanged edges of the main sheets. The method of securing the outside metal sheets at the eaves is very different to that on the metal sub-roof. The roof sheets on the latter type are prevented from lifting by the capping and outer wood roof, the fascia boards securing the sheets laterally on the car, making nailing unnecessary at the eaves. On the outside metal roof the main roof sheets or eave flashings are flanged at the eaves and secured to the outside of the fascia boards. This difference in the method of attachment on the early types of outside metal roofs, which were not designed to allow freedom of movement at the roof sheet intersections, resulted in cracked sheets and a considerable number of defective roofs, but eventually this was entirely overcome by providing ample sideplay at the main sheet capping, and applying eave flashings, giving the roof the necessary flexibility to withstand the cornering, weaving and bulging of the superstructure.

Advent of the All-Steel Roof

We find roofs today built entirely of steel. In comparison with the composite roofs already described, the all-steel roof presents an entirely new departure in design, both in regard to framing and roofing. The roof sheets are usually of 1/16-inch galvanized steel, but in some instances the sheets are 3/32-inch thick and span the full width of the car, providing in themselves the necessary protection against puncture or other hard usage. Additional reinforcement can be obtained by corrugating the roof sheets at suitable intervals. The carlines in most cases are designed to provide ready means of

connecting the roof sheets, in addition to supporting the roof, and bracing the superstructure of the car.

With the adoption of the all-steel roof, the question of flexibility becomes a very live subject. Some types provide for free movement of the roof sheets, in a similar manner to the flexible outside metal roof, while in others the roof sheets are flanged, capped and riveted together, forming in themselves an absolutely rigid roof. It is claimed for the first type that the roof should be sufficiently flexible to take care of the constant straining of the car body, while in the rigid type the roof is made strong enough to resist the straining of the body, and act as bracing for the superstructure.

The all-steel roof lends itself readily to the use of outside carlines, this arrangement giving the car a considerable advantage in loading space; other advantages being the reduction in fire risk, and final cost, owing to the life of the roof more nearly corresponding with other parts of the car and finally a greater safeguard against leakage is obtained by the use of thicker sheets, which resist corrosion and cracking to a greater extent, and as a result this type of roof is gradually meeting with more general approval.

An objection which is sometimes raised against the all-steel roof is the claim that under certain conditions it is liable to sweat, resulting possibly in damage to lading. For instance, freshly milled flour containing a high percentage of moisture, and which is usually hot when loaded, quickly raises the temperature of the car above that of the outside atmosphere. It is claimed that the metal roof being then subject to two widely varying temperatures commences to sweat, and that the resultant moisture is sufficient to damage the contents. It is questionable, however, if this is of enough importance to warrant special attention when building box cars for general service requirements, but as a measure of precaution effective steps are being taken to prevent the possibility of this occurring even under the most extreme conditions, and eventually there is good reason to believe that the all-steel roof will meet all requirements.

Conclusions

As previously mentioned, the double board roof is the most common type on refrigerator and stock cars today, and while it meets the requirements for stock cars, it is rather surprising that a better roof has not been previously adopted for refrigerator cars in order to protect more effectively the insulation. In making repairs to this class of car it is often necessary to renew the whole roof insulation, and ceiling, which have become waterlogged and decayed, owing to the poor protection offered by the double board roof. The entire side and end framing, with their insulation, are often affected in a similar manner, due to the water working down through the defective roof. These conditions are becoming better recognized, and as a result we find the outside metal roof now being adopted for refrigerator cars. Owing to the metal roof being a greater conductor of heat it might be necessary to increase the roof insulation, but the added cost would be more than offset by the saving in maintenance.

A car roof should be so constructed that repairs can be made quickly and at a minimum cost. The position of the roof in relation to other parts of the car does not lend itself to proper maintenance. Trucks, air-brakes and draft gear are constantly being inspected for indications of possible failure, but unfortunately, and all too often, the only warning received of roof failure is when the damage has actually occurred to the lading. Car roofs should, therefore, be as far as possible self maintaining. Corrosion is an important factor in modern roof maintenance and calls for a systematic method of painting, for it cannot be expected that the galvanizing will protect the roof sheets indefinitely. The best designed car roof will only last in proportion to the maintenance it receives, and the object should be to make the life of the roof equal to the life of the car.

Discussion

L. Brown:—Each year the average car goes on the repair track five times during the year. When a car is built the roofs are generally in good condition and very few are found leaking. The trouble is not in the new roofs but in the old roofs that have been in service for some time, very few of which do not leak. In looking over the defects in these cars we see that the boards are split, nails get loose and rust away and allow the water to get in through the nail-holes; metal sheets when unsecured, get loose, distorted and punctured. Caps over the inside metal roofs frequently become loose and the water follows the nail holes to the inside of the car. Nails securing the parts on the outside metal sheets work up out of the side plates and through metal sheets; parts securing the outside metal sheets frequently allow the water to get around the sheets, which wear away by friction and become cracked over the side plates.

The all-steel roof has less objectionable features than the other types and the condensation of moisture has been overrated in proportion to its importance, and the shipments which are damaged by moisture are few compared with the damage caused by water leaking in from the outside. The condensation inside may be eliminated by proper ventilation or by the use of non-conductive materials on the inside.

Objection has been raised to the rigid roof on account of causing derailments, but there is little justification for that theory. I have made tests of various roofs on empty cars and loaded cars with various types of roofs, and find that the additional force necessary to twist the cars having rigid roofs is negligible. The rigid roofs are not blamed for derailments of passenger cars which have such roofs and travel faster, have greater side bearing movement and have permanently heavier loads.

E. V. Harrison:—From an operating standpoint it is not so much the damage to merchandise from the roofs as from the side sheeting. During the past few years in the case of new cars turned out we have not had any side sheeting, with the result that considerable damage has occurred not only to flour but to other merchandise as well. I do not want to give any secrets away to the industrial people, but this is a thing which we have had to contend with both in regard to claims and damage.

James Coleman:—There are more loss and damage claims as a result of leaky car roofs than from any other direct cause, and I think the time is coming when the all-steel car roof will be adopted universally for the reason that it prolongs the life of the car, and if well constructed and properly applied will last almost the life of the car. The question has been raised as to the sweating of the steel roof in cars loaded with flour, but I think investigation will show that responsibility for this rests principally with the people who load the flour and fail to take precautions to prevent claims for damage. In October, 1919, a circular was issued by the U. S. R. A. to fifteen railroads at St. Paul and Minneapolis, where an embargo had been issued against the loading of flour in cars with all-steel roofs.

(Paragraph from U. S. R. A. Circular).—Upon further investigation it has developed that where flour is loaded in a warm condition in any kind of a car, whether *all steel or all wood roof*, if the temperature of the weather is very low, there will be condensation of moisture, due to the fact that there is no ventilation in the car and consequently it will cause this sweating.

The Western Weighing and Inspection Bureau has issued instructions on this subject, which read as follows: "In the interest of claim prevention, we should endeavor to prevail upon the flour mill people not to load their flour in a warm condition into cars during extremely cold weather; but, if they do so load it, then the flour should be covered with paper in order to protect same against the drippings from the sides or roofs of the cars."

Some all-steel roofs are constructed with a means provided

for ventilation at the eaves, and with this means any moisture deposited on the underside of the roof sheets will be evaporated by this circulation. This possibly would not provide circulation enough with hot flour in the car, from 60 to 80 degrees, but this means of circulation will provide for any moisture that may be deposited on the roof sheets under ordinary lading. In confirmation of this, I have never yet heard of a report of sweating of room except of reports made by the people of Minneapolis and St. Paul in loading flour.

With the years of experience that these people have had at Minneapolis and St. Paul, they now admit that moisture will be deposited on a roof of any kind when the flour in the car is loaded at a high temperature, and they have given instructions that some covering—paper or tarpaulin—must be put over lading when loaded at a high temperature, in order to prevent the moisture dripping from the roof; either from a wooden or all-steel roof.

H. R. Naylor:—We are getting to the time when the modern car roof will take the form of an all-plate roof. For some time it has been more or less of a thin plate roof, but I think in the development of the all-steel roof, the tendency will be to use sheets of heavier gage, say $\frac{1}{8}$ -inch thick or heavier, thus making a good solid plate roof. When this is done the roof will more nearly last the life of the car, whereas today the average roof has to be renewed two or three times in the same period. By adopting a roof of this type, there should also be a tendency to avoid designs which are in any way complicated in order to reduce to the minimum the possibility of leakage, and enable them to be easily maintained. The roof, therefore, should be designed with the least possible number of sheet joints, the joints being formed and secured in such a manner as to make them absolutely weather proof. Providing the roof sheets are protected from the straining of the roof frame, there would appear to be no necessity of providing for flexibility. The superstructure should be well braced to protect the roof framing, and the roof framing should also be braced diagonally to protect the roof sheets from undue racking and strain. If we take care of the strains set up in the superstructure and transferred to the roof framing, then we should be able to use an all-steel roof of simple design, which need not necessarily be flexible.

W. J. Hyman:—A few years ago I examined a great many outside metal roofs that had been in service from four to six years, and on some of these roofs the paint was scaling off, on others along the edges of the carlines the weaving of the car had caused the paint to rub off and naturally they had started to rust. If some of our paint manufacturers could supply a paint which would stay on without scaling under extreme weather conditions and be elastic enough to take care of the weavings of the car it would go a long way in prolonging the life of the outside metal roof.

Norman Holland:—The question of being able to make a paint which will stay on roofs is extremely simple. You can make anything if the consumer will pay the price. It is possible to make a roof composition that will stay on cars. A sample I have consists of sixteen coats of such a paint and is made for passenger car roofs. It would be too expensive to make it standard for freight cars, although it might not be too expensive if you figured it out from the standpoint of maintenance cost. The point is that in dealing with freight car roofs you have to consider the joint in your board, and you cannot expect anything to be elastic enough to stand one half inch warping, and I have seen warps that were one and three-quarter inches.

SAFETY FIRST.—Don't swing a sledge or hammer that you know is working loose on the handle, thinking it won't come off till "next time." You may not be hurt, but what about "the other fellow."

Interior of the Erecting Shop

EXTENSIVE ADDITIONS TO C. & O. SHOP

New Erecting, Machine and Blacksmith Shop and Brass Foundry Erected at Huntington, W. Va.

IN 1916 the Chesapeake & Ohio decided to enlarge the facilities for handling repairs to equipment at the main shops at Huntington, W. Va. The equipment owned by the road includes 923 locomotives, 395 passenger cars and 52,324 freight cars, and the increase in the amount of rolling stock as well as the increase in the size of the motive power necessitated an enlargement of the shops. Additional rea-

sons for changes were found in the poor grouping of the existing buildings and the inadequate provision for lighting, heating and transporting material. The site of the Huntington shop is a plot approximately 5,000 ft. by 850 ft., or about 100 acres, located north of the main line tracks. After a study of the requirements an expansion of the shop to three times the existing size was decided upon. Plans were laid for carrying out the changes without interfering with the operation of the shop and the improvements were divided into three stages. The first stage has now been completed, the second will probably be carried out in 1921 and the third without material delay.

increasing the floor area for this work from 8,500 sq. ft. to 14,000 sq. ft.; (2) the building of an addition to the blacksmith shop, increasing the area from 22,000 sq. ft. to 30,000 sq. ft.; (3) the removal of the machinery from the freight car blacksmith shop to the new addition to the locomotive blacksmith shop; (4) the erection of a new longitudinal erecting and machine shop at the north end of the existing machine, erecting and blacksmith shops; (5) the installation of a 10-ton traveling crane between the blacksmith and machine shops, extending from the new erecting and machine shop to the storehouse; (6) the enlargement of the transfer table pit and the installation of the new transfer table; (7) the rearrangement of the steam and gas piping and electric wiring.

West End of the Blacksmith Shop

Interior of the Power House

sons for changes were found in the poor grouping of the existing buildings and the inadequate provision for lighting, heating and transporting material.

The site of the Huntington shop is a plot approximately 5,000 ft. by 850 ft., or about 100 acres, located north of the main line tracks. After a study of the requirements an expansion of the shop to three times the existing size was decided upon. Plans were laid for carrying out the changes without interfering with the operation of the shop and the improvements were divided into three stages. The first stage has now been completed, the second will probably be carried out in 1921 and the third without material delay.

First Stage of the Improvements

The work included in the first stage of the plan comprised the following steps: (1) the erection of a new brass foundry,

in developing the plans and to handle the construction work of the first stage.

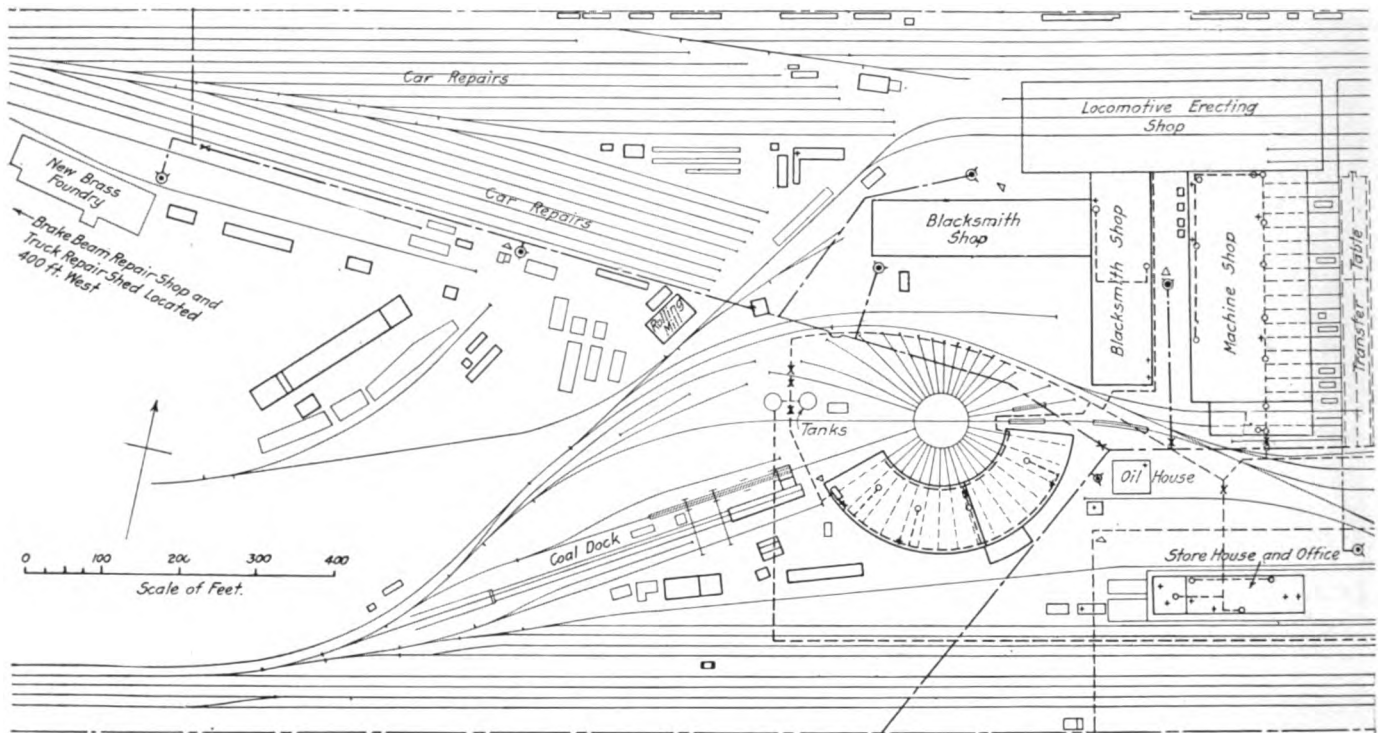

Projected Improvements

Second Stage.—The second stage consists of: (1) the removal of the present transverse erecting shop, which has been

in service for 40 years, and the construction of a new and modern transverse erecting shop equipped with overhead cranes; (2) alterations to the present machine shop in the way of improved lighting and additional sanitary and toilet facilities and general repairs on the building; (3) an exten-

tion to the roundhouse; (8) the construction of paved roadways to displace a greater part of the present plank roadways within the shop grounds; (9) enlarging the boiler and tank shop.

Third Stage.—The third stage consists of: (1) the filling

General Arrangement of the Shops

sion on the office building to provide approximately 11,000 sq. ft. floor area; (4) the construction of a new reinforced concrete, fireproof oil and paint storage house including

of an area of low ground at the east end of the shop site and the construction of approximately 35,500 ft. of tracks for a new steel car repair shop and yard; (2) the construction of

West End of Erecting and Machine Shop, Blacksmith Shop at Extreme Right

storage tanks, pumps and modern oil house equipment; (5) an extension to the boiler plant to permit the installation of approximately 1,000 additional boiler h.p.; (6) the construction of a new lumber dry kiln and equipment; (7) an ex-

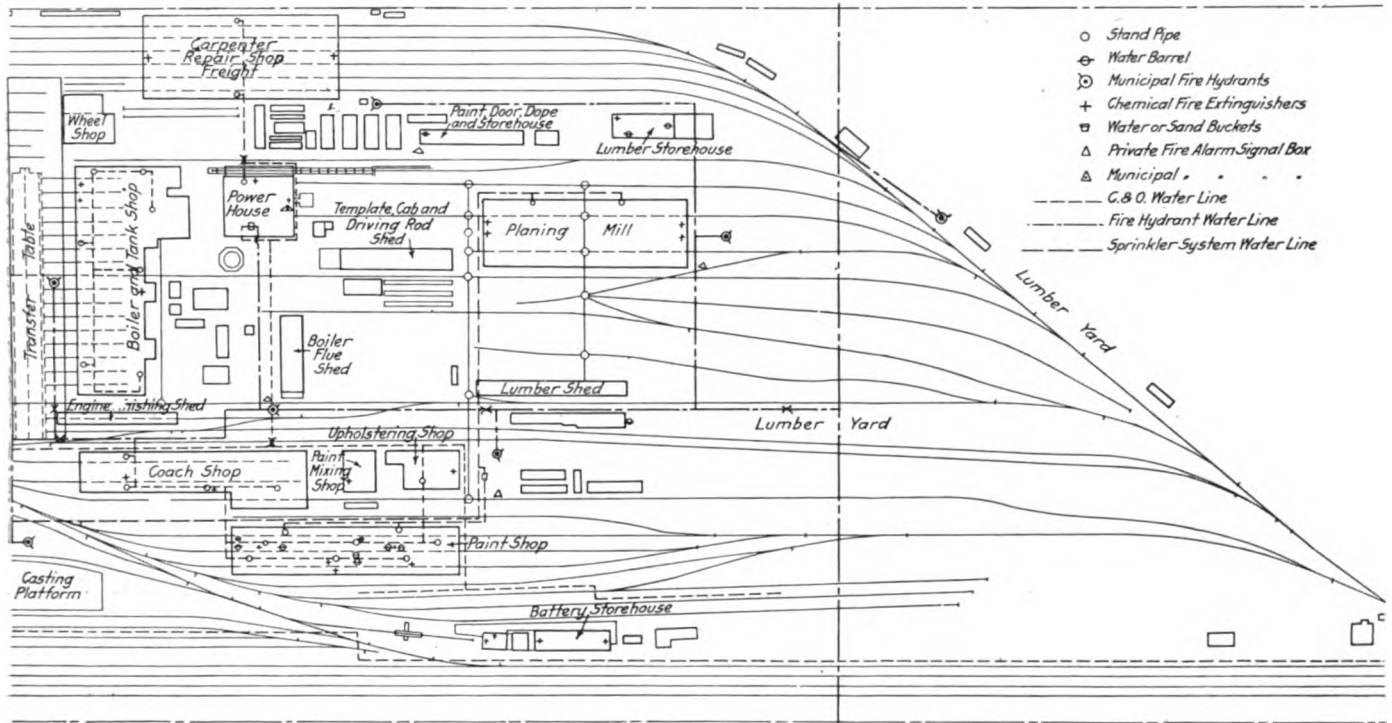

new steel car repair shop approximately 1,200 ft. long, to shelter at least 68 steel coal cars undergoing repairs, this building to be equipped with modern traveling cranes; (3) the construction of a new freight car shop, blacksmith shop.

wheel shop and bolt shop complete with installation of equipment; (4) the construction of a new coach and paint shop and additional transfer table and pit serving this shop; (5) the construction of a new wood freight car repair shop for housing approximately 60 wooden freight cars undergoing

These three stages of the development, when completed, will be sufficient to take care of the needs for many years.

General Layout of the Shops

The facilities at Huntington shop include locomotive shops,

of the Chesapeake & Ohio, Huntington, W. Va.

repairs; (6) remodeling the present coach shop and converting it into a truck shop, tin and pipe shop, polishing and upholstery department.

With the completion of these new freight car repair faci-

car shops for both freight and passenger equipment, a brass foundry, a storehouse, an extensive reclamation plant and a complete engine terminal. As will be noted from the drawing of the shop layout, the tracks leading to the roundhouse

Heavy Machine Bay in the Erecting Shop

ties, the freight car work is to be removed from the present west end of the site available for a future extension to the locomotive repair shop and a large area available for a future reclamation plant and possibly an iron foundry.

leave the running tracks along the main line near the southwest corner of the shop grounds. These tracks also give access to the reclamation plant, to the west ends of the erecting and blacksmith shops and also to the south end of the

machine shop and the transfer table. The approach to the car repair shops and storehouse is from a lead at the east end of the shop. The locomotive shops can also be reached indirectly over these tracks. At the northwest section of the plot is a large car repair yard, served by two leads, and the brass foundry.

As the principal additions to the shops included in the first stage of the development, which was commenced in 1918 and

to the truss. The building has concrete foundations and footings, concrete walls to the window sills, with brick side and end walls and pilasters. The framework and trusses of the superstructure are steel, over which is applied a wood roof covered with four-ply asphalt roofing. A ventilated steel sash is used in the side walls and monitors. The floor is of creosoted wood block over a concrete sub-base. Wooden doors of substantial construction are used. The erecting bay

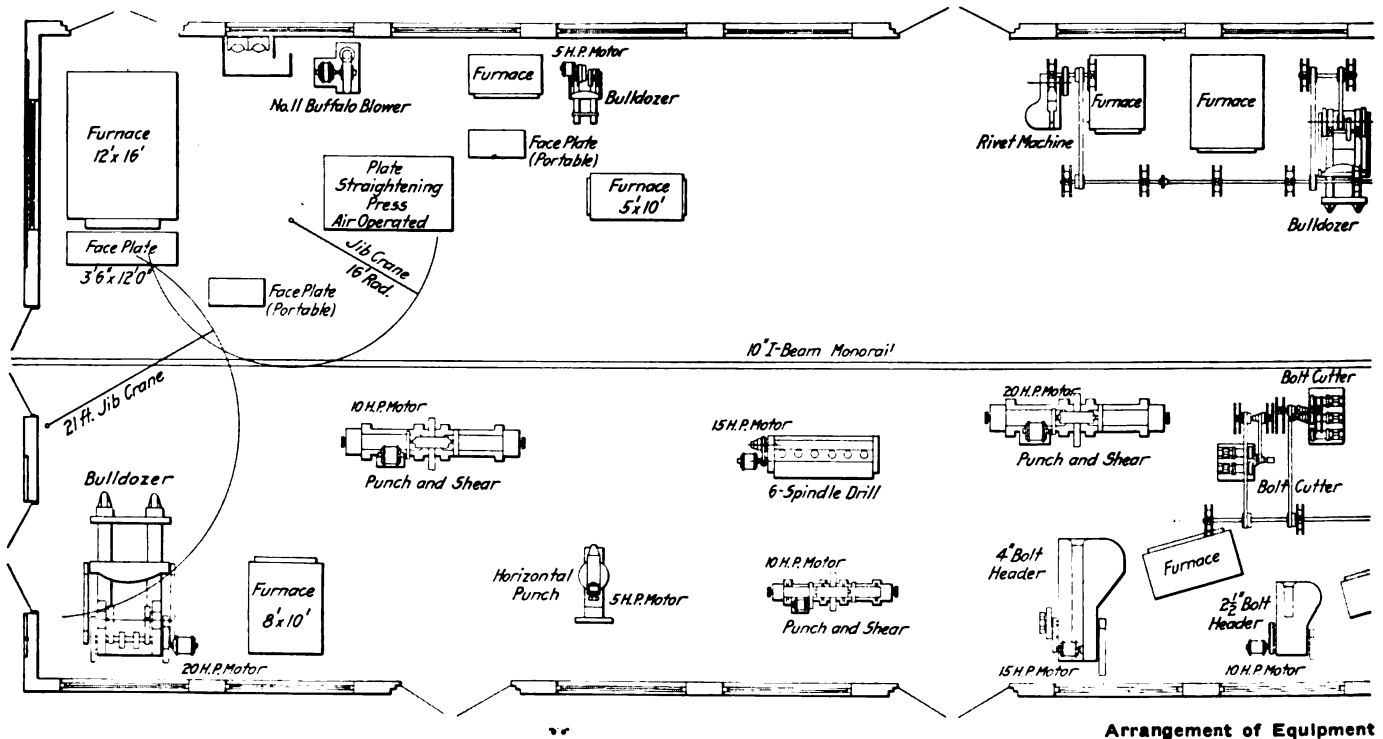

completed in 1919, are all in connection with the locomotive facilities, the detailed description which follows is confined to that section of the plant.

Erecting Shops

Locomotives undergoing repairs are placed on two sets of tracks, the Mallet and Mikado locomotives being shopped in

has two 150-ton cranes with auxiliary hoists of 10 tons and 5 tons capacity. The machine bay is served by one 10-ton crane.

The machine shop and blacksmith shop extend south from the erecting shop and at right angles to it. The boiler and tank shop is in a separate building at the eastern side of the transfer table pit, which has been enlarged. The rebuilt

the new longitudinal erecting shop, while the smaller power is set on transverse tracks in the machine shop building. The new erecting shop is 400 ft. long and 113 ft. wide. It is divided into an erecting bay 70 ft. wide and 41 ft. to the bottom of the roof truss, and a machine tool bay 43 ft. wide and 24 ft.

transfer table was made by extending the old table along practically the same lines but of heavier construction, as shown in the drawing, with the addition of more powerful motor, gearing and shaft. A special type of drive for the table was designed by the mechanical department with a

50 hp. 230 volt, D. C. crane motor geared to a drive shaft having shifting gears to mesh with the main drive of the table, or for driving the pulling drums, one of which is located at each end of the table for pulling engines on or off the transfer table.

Between the machine shop and blacksmith shop is a crane runway 50 ft. wide, which extends 520 ft. from the erecting shop, ending over the unloading platform at the storehouse.

machine shop. The wheel department, which is located at the south end of the machine shop, is equipped with two axle lathes, a truck wheel boring machine, a boring mill for tires and wheel centers, a wheel press, and a 96-in. wheel lathe. Two wheel lathes of lighter construction are used for truing journals, for turning mounted wheel centers and similar work. On practically all locomotives on the Chesapeake & Ohio lateral wear is taken up by brass liners on the driv-

Erecting Shop

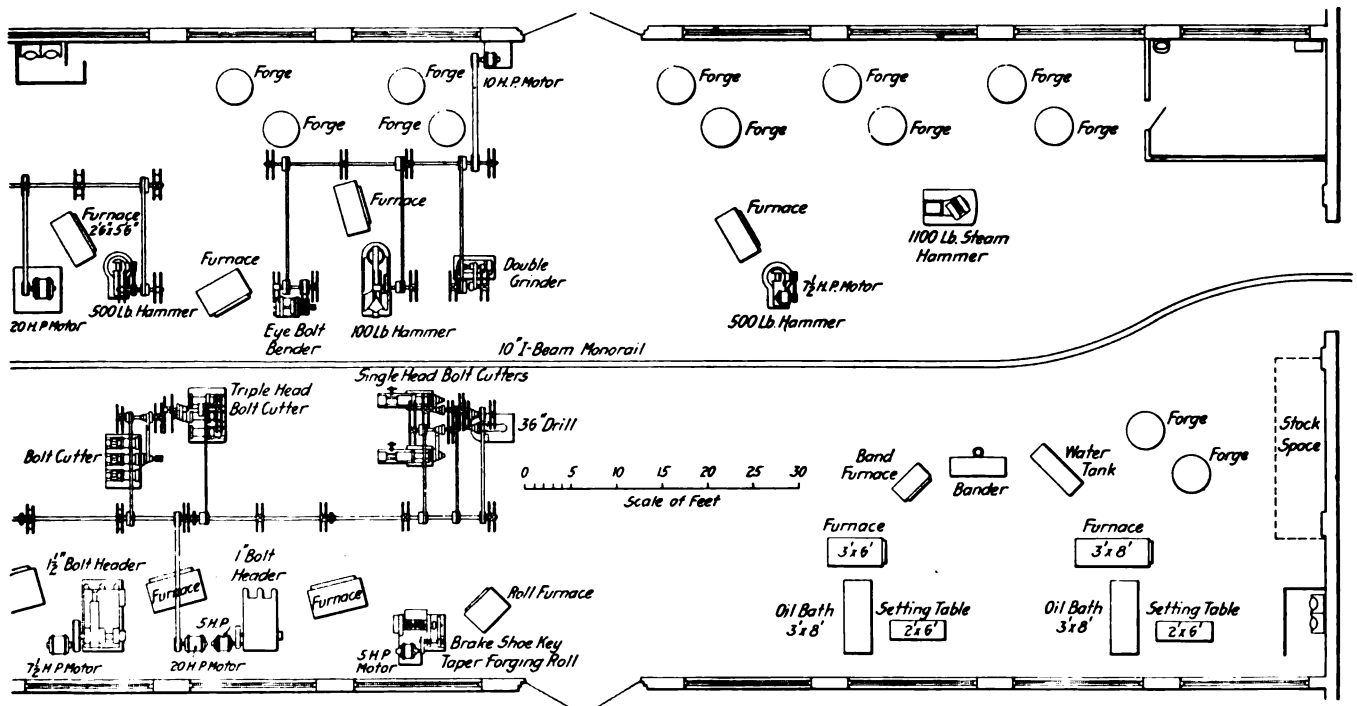

the Heavy Machine Bay

Locomotives enter the erecting shop by the center track at the west end or across the transfer table at the east end. They are stripped on this track and are then set on either of the two side tracks, each of which is long enough to hold four Mallet locomotives and two non-articulated engines.

In general, the parts removed for repairs follow a definite course through the machine shop or the heavy machine bay

ing box and very little facing on the driving wheel hubs is necessary.

The driving boxes after being cleaned in the lye vat are brought into the heavy machine bay and pass to the 100-ton vertical hydraulic press, where the crown brasses are removed and the hub liners cut off. New brasses are turned on a vertical turret lathe in the

In the New Blacksmith Shop

and are delivered to the erecting shop when completed. Driving wheels leave the shop by the transverse track leading under the crane runway, which furnishes considerable storage space. The driving box cellars are pulled out by the crane, then the wheels are taken to the south end of the

machine shop. They are then slotted to fit the box on the crank planer and are pressed in. A cast brass hub liner is then fastened to the box with brass studs, and the brass liners for the shoe and wedge fit are renewed if necessary. The shoe and wedge faces are then planed and the box is bored

and faced, the grease grooves being cut before it is removed from the chuck. Some boxes have the crown brass and hub liner cast in place. This work is done in the brass foundry, the boxes being returned to the heavy machine bay for boring and facing.

Main and Side Rods

The main and side rods after being stripped are placed on trestles in the machine bay. The bushings are removed with a hydraulic press and new bushings turned on the vertical turret lathe are pressed in.

New rods coming from the blacksmith shop are first milled on both sides on the slab milling machine. They are then taken to the lay-out table and the outline is laid out. The edges are then finished on the vertical milling machine and the slotter, except that the main section of the rod is finished on the slab milling machine. The holes for the bushings are then drilled on a two-spindle rod boring machine. The pistons and rods, valves and link motion are handled in the old machine shop, on tools and fitting benches grouped near the north end of the shop.

The new erecting shop is used exclusively for Mallet and heavy non-articulated locomotives. The lighter power is dismantled in a stripping shed at the south end of the machine shop, the engines being transferred to the 16 pits in the old machine and erecting shop or the two pits in the

A Section of the Interior of the New Blacksmith Shop

machine bay of the new shop by means of the transfer table, which has been rebuilt and enlarged to facilitate handling heavy locomotives.

Blacksmith Shop

The blacksmith shop occupies a brick building at right angles to the new erecting shop and an addition on the west side of the original blacksmith shop, which forms part of the new construction. The new building is 290 ft. by 72 ft., of the same type of construction as the erecting shop.

The heavy parts and locomotive work are largely handled in the older building. In the new shop are located the spring department and the facilities for handling the blacksmith work for cars. All the tools in this section are motor driven. A monorail crane running down the center of the shop facilitates handling heavy parts. The spring department is located at the extreme eastern end of the shop. A series of furnaces and forging machines is located along the center portion of the south wall. Adjacent to them are drill presses and bolt threaders, this arrangement making it possible to finish many of the parts completely before they leave the shop. Along the north side of the shop are six forges and near them are placed one 1,100 lb. steam hammer, Beauty hammers and Bradley hammers.

The west section of the shop is equipped for making steel car parts. In this section are three combined punches and shears, one 4-spindle arch bar drill, two bull-dozers, a horizontal punch and a pneumatic straightening press, besides the furnaces necessary for heating the work.

Powerful Transfer Table at Huntington Shop

Directly south of the blacksmith shop is a shed where bars are stored. Just outside one of the doors is a shear house where bolt stock is cut to length before being brought to the blacksmith shop. In this building there are a combined punch and heavy bar shear, a light bar shear and a washer press for manufacturing washers from scrap material.

The boiler and tank shop is located east of the turntable pit and has 16 transverse tracks. The north end of the shop is used for pipe and sheet metal work and an addition at the northeast corner is equipped for handling tubes and flues. The boiler shop tools are located along the east wall of the shop and are served by a monorail crane. The tracks are

East End of the Brass Foundry

used principally for repairing tenders, as it is the practice to cut and flange the firebox sheets in the boiler shop and to assemble them within the boiler in the erecting shop, where they are welded and riveted.

Power House

The power house has six 275-hp. Sterling boilers, carrying 150-lb. pressure. Four of the boilers are fired with natural gas and two are fitted for burning coal and shavings, in order to provide for disposition of the refuse from the planing mill. The boilers are completely equipped with steam flow meters and are fed through a Cochrane metering heater fitted with a graphic recorder. An additional open heater is located in the basement of the power house and a cooling tower is placed outside of the building.

In connection with the installation of the second heater a unique method of testing boilers in the erecting shop was installed. The feed pumps connected to the open heater now lead through a main to the erecting shop. A pressure of 125 lb. is carried on this line and in case boilers are to be tested this pressure is raised to the desired amount by two portable electric triplex pumps in the machine shop.

The electric generating apparatus consists of two 750-kw. Curtiss turbines, direct-connected to an alternating current generator, with a capacity of 1,120 amperes at 480 volts. There is also a 25-kw. turbine for excitation and a motor generator set driven by a 35-hp. induction motor. The direct current required for the shops is furnished by a motor generator set of 250 kw. capacity. Compressed air is provided by two steam driven compressors, with capacities of 2,130 and 3,300 cu. ft. per minute, and a motor-driven compressor, with a capacity of 1,730 cu. ft. per minute.

The first stage of construction included a general rearrangement of service pipe lines and electric transmission lines to serve the new shops. An addition to the engine room of the power house was built to provide for the installation of the 1,730 cu. ft. capacity direct connected synchronous motor driven air compressor.

Brass Foundry

The brass foundry is located in a new building, which is situated at the extreme west end of the shops. The building is of concrete and brick construction with a double monitor roof and is 288 ft. long by 58 ft. wide. The location is convenient for receiving material and is also adjacent to the freight car repair yard, where a large number of brasses are used. The finished material going to the storehouses is readily handled on electric trucks; that shipped to outside points is loaded directly into the cars at the brass foundry.

The extreme western end of the foundry is used for coke storage and adjacent to this is a row of eight pit furnaces for melting in crucibles. The core ovens are located at the sides of the furnaces. The molding floor extends from the furnaces beyond the center of the shop and on the north side there are two Rockwell and one Monarch tilting furnaces fired with natural gas. Along the north wall on either side of these furnaces is a series of bins with doors opening outward, thus making it possible to unload the scrap brass directly from the cars into the bins. A magnetic separator is placed adjacent to the bins used for brass turnings. A monorail track carrying a one-ton hoist is installed in front of the scrap bins and the two sets of furnaces. Another track forms a loop over the molding floor. In addition to this the molding floor is served by six small cranes with one-ton chain hoists.

At the eastern end of the molding floor there is a pair of Nichols molding machines and a Berkshire molding machine, all of which are used for making journal bearings. Just east of the molding floor is the section in which the bearings are babbitted and other castings finished. Two tumbling barrels are located in a small lean-to on the south side of the shop. Along the south wall are located a sprue cutter, two stand grinders, a two-spindle boring machine, a swing grinder and two babbitt furnaces. These furnaces are used for babbitting crossheads and similar work and two other

View Looking West in the Brass Foundry Showing Molding Floor and Tilting Furnaces

furnaces are provided at the north side of this section, one of which is used for melting off the babbitt and the other for tinning and babbitting journal bearings. The extreme eastern end of the building is used for storage of the finished castings. For convenience in loading outgoing shipments the room is provided with a pneumatic elevator. A dial scale is used for weighing castings. The space above the casting storage room is used for the storage of patterns. Adequate provision has been made for the comfort of the workers. Above the scrap bins east of the tilting furnaces are located locker rooms and shower baths. This foundry has a capacity of 15 tons daily and supplies brass castings for both cars and locomotives for the entire C. & O. system.

ALL IN A DAY'S WORK*

Hot Boxes, Derailments and the Grievance Committee
Add Interest to the Life of the General Foreman

BY M. S. ROBERTS

EARLY one morning during the recent severe winter weather, I called at the office of a general car foreman at a busy terminal, to investigate with him certain conditions which were causing an epidemic of hot journals on through passenger trains.

I had known John Swinton, the general foreman, for many years, and so walked, unannounced, into his private office, where I found him busy at the telephone, getting a line on train detentions from the dispatcher, and, judging from the appearance of his memorandum pad, there had been a considerable number.

"Jim," said John, after greeting me most cordially, "it looks as though we would have to give the cars on trains 1

In a Few Minutes John and the Committeemen Came Out of His Office

and 15 extra careful attention for a few days, because these two trains have been performing"—Here the telephone demanded immediate silencing.

"Hello, chief; this is Swinton talking."—"What do you say? Broken arch bar on the wrecking derrick! Fine business. They were just returning from a derailment at ZX to clean up a bad mess in our passenger storage yard."—"Did Jones tell you how long it would be before he could move?"—"Good! One hour's delay won't tie us up here too badly, and I will say that it certainly pays to carry these repair parts on the wrecking outfit."—"Sure thing, you can see what it would mean if we had to send the arch bar out to ZX from the terminal."—"Good-bye, chief."

"Well, Jim," resumed John, "getting back to our hot journals. I was about to say that trains 1 and 15 burned things up pretty badly again last night, and you and I had better camp out on the equipment this morning to see if anything is being overlooked in the yard. Let's start now while the going is good."

On the way out we met the grievance committee coming in to see John, so he asked me to make myself comfortable in the outside office while he heard the men's complaints. The session was surprisingly brief, for in a few minutes John and the committeemen came out of his office. They

were all apparently quite happy and it seemed probable to me that the men had carried off most of the honors in the argument.

"John," I remarked, "it did not take the boys long to put it over you that time."

"You are quite wrong, Jim," said John, smiling, "for it was more nearly the other way around. Two cases were discussed: the first one involved a shortage in a man's back pay adjustment, due to an oversight on the part of our timekeeper, and will, of course, be promptly adjusted; the second case presented proved to be without foundation, and after I had read and explained a couple of the rules of the National Agreement to the committee, they admitted their error and promptly withdrew the grievance. So you see, Jim, the meeting was mutually satisfactory."

"This is certainly a surprise to me," I exclaimed, "and if it is a fair sample of your sessions with the grievance committee, you certainly are more fortunate, or probably more diplomatic, in handling men than are many supervising officers of my acquaintance."

"I don't know about the diplomacy part of it," laughed John, evidently pleased by what I had said, "but I do know that boys here have a very fair attitude toward the company, and they seem very willing to be set right when they make errors in applying the many orders, supplements, amendments, addenda, interpretations, rules and docked decisions, with which we have had to struggle during the past eighteen months. They are not apt to present grievances until they are reasonably sure of their ground, and for this reason, I believe, do not spend their time and waste mine by following me around the territory bringing up petty grievances."

"On the other hand," he continued, "we have made an honest effort to line up to all the awards and agreements covering wages and working conditions. The men know our attitude and feel that they have been given a square deal. Confidentially, I feel that dealing with the men through their committee has been to my advantage rather than the contrary, because the disciplinary effect of this method on the rank and file has, so far, been wholesome. Of course, I probably would feel very different if the committee members were inclined to be radical, but, fortunately, these men have, up to the present time, proved themselves to be very fair minded and reasonable."

I was most interested to hear what John had to say on this important subject. There is no doubt in my mind that his success in dealing with his men is the result of his broad-minded attitude toward them, to which they naturally responded in kind.

Without further interruption, we proceeded to the passenger storage yard and began making our inspection of the journals, bearings and packing on the equipment which had been causing so much trouble of late.

Several journal bearings were found which showed signs of linings starting to crush out at the sides, and, on removal, most of them proved to have linings slightly cracked along the crown. I was strongly of the opinion that this condition was caused by excessive pounding due to lack of resilience of the track on account of the severe cold weather and deeply frozen roadbed; all of which resulted in subjecting the jour-

*Entered in the Railway Mechanical Engineer's prize story contest.

nal bearings to an abnormal shock, and the consequent cracking of the weakest part thereof, namely, the linings.

John agreed with me, but pointed out another serious feature, which he claimed to be at least an important contributing feature in causing the hot journals. The journal box packing now being furnished as a substitute for long fibre wool waste is of a very inferior quality. It disintegrates after a few days' service and becomes very soggy, and, in this condition, soon resembles soft mud. Lubrication, under these circumstances, becomes questionable and there is little doubt that many hot boxes can be charged to this kind of packing.

We discussed this matter thoroughly and decided, until such time as a better grade of packing became available,

John Agreed With Me, But Pointed Out Another Serious Feature

to use a mixture of reclaimed long-fibre wool packing with the inferior grade of packing now in stock, because some benefit could be secured from the springy action of the old packing and it would, at the same time, result in better capillary transmission of the oil to the journals.

We had just about completed this inspection and had made arrangements to repack all the journal boxes on the two trains, when a messenger handed John a rush communication. After reading it he said, "It looks, Jim, as though we would have to part company for the rest of the day, because the pleasant tidings which I have just received direct me to meet one of the federal inspectors, right away, and to accompany him while he makes an inspection of freight car repairs on the repair tracks. If I can get away from him on time, I am expected to attend the regular monthly safety meeting in the superintendent's office this afternoon."

I then suggested that I would gladly look over more of the passenger cars and would let him know later in the day whether I had anything more of a remedial nature to offer.

"Thanks, old man," he said, evidently relieved at my suggestion, "I hate like the mischief to leave you this way, but it is mighty fine of you to give me the benefit of your experience, and I trust that you can spare the time to go over the other trains. Well, so long, Jim, I must hurry now. It would not do to keep my friend from Washington waiting."

Shortly before six o'clock that evening, I went back to the general foreman's office, half expecting not to find him there so late. But he was in, apparently having arrived there just ahead of me, for he was looking over a couple of reports which covered the day's output of the freight and passenger repair tracks.

After briefly telling him what I had observed in connection with journals and lubrication since he left me, earlier in the day, I asked him if he had reached the safety meeting in time. "Yes, indeed," he answered, "I was able to satisfy the Federal man in a very few minutes. He was interested,

principally, in keeping light repair cars moving from the repair tracks promptly. We have been making a campaign on this very thing for several weeks past, and our records showed to his complete satisfaction that, practically without exception, no light repair cars are being held over night. So he did not stay long with me, and I had just time enough left to get a bite to eat and to make the safety meeting on time.

"Jim, you have certainly put in a very full day, and I appreciate the assistance you have given me. There is a train leaving in about ten minutes, and you had better start for home," he urged, "or else your good wife will think some accident has befallen you."

"You had better call it a day yourself, John," I argued.

"Not for a little while, yet," he said, "I will go as far as the station with you, but I still have to see the night foreman for a few minutes and then I will go home."

"I don't suppose you have many days as busy as this one has been, do you, John?" I asked.

"Why, this was what I would call an average day," he laughed, "and, if the telephone behaves at all well tonight I will consider that it has been a very satisfactory day."

By this time we had reached the station and, after bidding John good-bye, I hurried for my train.

As I traveled homeward that night, I could not help thinking how typical my friend is of the great majority of rail-

I Went Back to the General Foreman's Office Half Expecting Not to Find Him There

road operating officers—cheerful, uncomplaining, serene; most congenial when busiest; and blessed with an optimism taught by years of exacting railroad experience. There is surely romance in their day's work, even though they probably never think of it in just that way.

MR. MCADOO'S INFLUENCE.—Horatio Alger's heroes may have to look to their laurels, according to a Canadian paper. A callboy of the Grand Trunk is likely to write his career as "From call boy to president." No clock watcher is this youngster. He has just drawn a pay check for two weeks, for \$109.35, the result of his overtime efforts as a call boy. At this rate he is drawing a salary on the basis of \$218.70 a month, which is more than the chief clerk—his boss—receives. Several other officials admit that he is getting more than they, says our Canadian contemporary, "but they explain that the scale set in the McAdoo award is responsible for the anomaly."

SOME NOTES ON ERECTING SHOP PRACTICE

**A Definite Program and Attention to Details
are Essential to the Operation of an Erecting Shop**

BY C. P. HUBBARD

Erecting Foreman, Hornell Repair and Construction Corporation, Hornell, N. Y.

THE purpose of this article is to enumerate the various operations performed in the erecting shop in making standard classified repairs and to recommend performances for each class of repairs rather than to describe the operations themselves. The ever-increasing size of power is emphasizing the necessity of having the back shop relieve the roundhouse of heavy repairs, and as this work generally comes under the present Class 4 and 5 repairs, these operations should be distinguished from those performed in Class 1, 2 and 3 repairs. Important betterments, such as the application of superheaters, outside steam pipes, improved cylinders or valve gears, can best be made while undergoing Class 1 and 2 repairs, as when Class 3 repairs are needed the boiler and cylinders are often in good condition and require routine repairs only.

Advance information of the condition of the locomotive should be furnished so that the necessary material will be available without delay, and a comprehensive report made from observation of the locomotive in service should accompany it to the shop. When Class 4 and 5 repairs are required the report will indicate the necessity of testing cylinders and steam pipes, but these tests should always be made when making other classes of repairs.

Dismantling can best be performed by a separate gang, who will remove, clean and deliver the various parts to the proper department with their report of defective or missing material. This gang will also make the preliminary test of the boiler and cylinders and with the inspectors report their findings.

Light Classified Repairs

While preparing for Class 4 and 5 repairs, when the removal of all drivers is not intended, a careful inspection of all parts should be made in order that nothing will be overlooked that would necessitate the further removal of drivers until the next shopping. It is considered good practice by some, whenever any driving boxes require attention, to remove the complete set for a more detailed inspection. All motion work, spring gear, brake rigging, frames and connec-

tions are to be examined and put in condition for the mileage expected. Steam chests, crossheads, cylinders, steam pipes, tubes and flues and all other parts are to be made fit, so that they will not require overhauling until the next shopping.

When all wheels are removed the shoes and wedges should be lined, as required in Class 3 repairs, with the exception that driving boxes and shoes and wedges that are in good condition may be trued up, as they should run until the next shopping before going to the expense of bringing the entire set to standard. Eccentrics should be turned if found worn over 1/16 in. and their straps reduced, if needed, or replaced if the lateral motion is in excess of 1/8 in. Engine truck and trailer truck boxes and bearings are to receive needed repairs, main reservoirs are to be tested unless the date thereon indicates that they will run until the next shopping before the test is due. Air brake equipment, lubricators, injectors, safety valves and other appliances should be cleaned or repaired, so that the engine will be able to make the mileage required without the removal of heavy parts by the roundhouse force.

Handling Heavy Repair Work

In taking up Class 3 repairs the fact should be borne in mind that the work on the parts mentioned above is the same as required for the same parts in Class 1 and 2 repairs. As full mileage is expected, the engine is to be stripped of all parts under the running board, except such frame connections as show unmistakably that they need no repairs. The frames are now to be thoroughly cleaned and whitewashed. After the frames are dry they are to be sledge-hammer tested for defects and all bolts examined and removed unless in perfect condition. Particular attention should be given to cylinder and frame splice bolts, and if doubt exists as to the condition one bolt should be removed where the question arises and examined to determine the advisability of removing further bolts. If then there is any doubt as to their condition it is better to remove all bolts, as repairs of this kind between shoppings will reflect badly on the erecting shop. All bolt holes should be trued up with standard reamers and good-fitting bolts applied. Frame crossties and pedestal braces are

now to be adjusted to fit in place, worn pedestal jaws trued up and, if needed, restored to proper shape by autogenous welding. Where spring hangers are liable to chafe the frames a steel liner may be bolted or welded in place. Particular attention should be given to the guide yoke, as generally it will be found in need of some repairs. Boiler supports will need some attention, and where shoes are used under the front they will require truing up and lubricating. Worn draw castings can often be reclaimed by autogenous welding, but they should receive special attention in regard to the condition of the draw bar pin holes and the connection to the frames, as they are hard to repair between shoppings.

When the frames are bolted completely and the pedestal braces are in place with the jaws finished, the centers are to be laid out on the main jaws. This may be done in any recognized manner, but the prevailing practice is to use lines parallel to the frames with a straight edge set square and proving the centers by it. With the main centers located, the other centers are marked off and the shoes and wedges put in place and laid out. The importance of accuracy in this operation is very great, and accurate machining of driving boxes should be insisted on, as the engine wheels will not tram properly if poor work is allowed. A standard proof mark on the shoes and wedges will determine if any liners are required, and in planing, if the shoe or wedge will not true up to the proof, it should be planed so that one liner of standard size boiler steel, not less than $\frac{1}{8}$ in. thick, may be used, this liner to be securely riveted in place.

All spring rigging should be thoroughly overhauled, attention being given to see that the saddles set square on the driving boxes. After spring rigging has been repaired and reapplied, the frames and spring rigging may be painted and the engine is ready for the wheels.

Details That Require Special Attention

If the cylinders do not need renewing they should be bored if out of round $\frac{1}{16}$ in., or bushed if they will not true up to $\frac{5}{8}$ in. over the correct size. Valve chamber bushings should be bored to $\frac{1}{8}$ in. oversize or renewed if already oversize, and packing and bull rings should be carried in stock in these sizes. If slide valves are used the seats should be trued up until they reach $\frac{1}{8}$ in. thickness, when they are to be faced flush and false seats applied. Slide valves that have reached $\frac{5}{8}$ in. or less in thickness are to be renewed and the pressure plates are to be lined and planed true, so that there will be $\frac{1}{8}$ in. clearance when drawn down in place. Guides should be carefully lined, so that the crosshead will be central with the bore of the cylinders and straight bolts fit to a light driving fit and single liners should be applied to hold the guides in place.

When the boiler work is complete, the test made and defective flues replaced, the steam pipes applied and all mountings applied to the boiler, it should be charged with steam or compressed air and the steam passages should be blown out, after which the ports should be examined to locate lodged foreign matter. This done, the steam chests should be closed and the passages to the cylinders blown out by placing the valves in the forward and back positions. The pistons and cylinder heads may now be applied and the stroke of the piston measured, making sure that the piston will have at least $\frac{1}{2}$ in. clearance over all.

It is advisable that all work possible, such as the application of air pumps, stacks, sand boxes, bells, generators, cabs, injectors and the like, be handled as early as possible in the erection of the engine in order to avoid the confusion of a large number of men working close together when the engine is nearing completion.

Main reservoirs are due for hammer test at the time when heavy repairs are made, and should be replaced if found defective. A 16-in. reservoir is to be condemned if any part

is $\frac{3}{32}$ in. or less in thickness, 18 in. to 20 in. reservoirs if $\frac{9}{64}$ in. or less and 22 in. and over if $\frac{3}{16}$ in. or less, or if any reservoir will not stand 170-lb. hydrostatic pressure.

All brackets or other attachments to the boiler should be left securely fastened in place, special attention being given to these particular parts when the lagging is off the boiler.

Engine truck and trailer trucks should be well built and should have not over $\frac{1}{4}$ -in. lateral motion when new, the same rule applying to driving wheels.

Planning the Final Operations

After wheels and trucks are applied, shoes and wedges are put in place and the wheels trammed. They will tram if all the work is correctly done, and the wheels should be parallel to lines run parallel to frames, as was done when main centers were laid out. After any errors are corrected, the pedestal braces may be bolted in place and the ash pan, brake rigging and other parts underneath the engine applied.

The motion work should be applied by this time and it should hang free, being without any cramp or strain. The subject of valve setting has been dwelt upon so much that it is not necessary to discuss it here, except to say that this work should be done according to instructions from the proper authority and should not be left to the judgment of the man who does the work. With the valve setting complete and adjustments made, the rods are ready to be applied and adjusted for the proper travel.

With the last details complete, the engine leaves the shop, the tender is coupled and the engine fired up. The pop valves are set, the air brakes adjusted and the engine is run a few revolutions, with the cylinder cocks out to make sure that the cylinders are clean. The engine should make the trial trip with the cylinder and steam chest casings off, the better to locate any leaks that may develop.

In order that all the details necessary to the operation of the erecting shop may be successfully performed, it is necessary that some definite program be adopted. The subject of scheduling or routing deserves serious attention, but the successful operation of the shop depends upon the co-operation of all departments toward that end.

RADIUM.—A recent issue of the Scientific American contains an interesting account of radium. It is stated that so far there are only three or four companies in the world producing radium commercially, and the product of the largest of these is about an ounce a year. The total amount of pure radium in the world today is only about five ounces, the market value being \$120,000 a gram, which is one twenty-eighth of an ounce. Only two practical uses have so far been discovered. The first is for medicinal purposes and the second is in the production of the luminous material used on watch and clock dials and as locaters for electric switches, etc. Already more than 4,000,000 watches and clocks have been treated and hardly a third of an ounce of radium has been used in the production of all of the luminous material required. In making this luminous material zinc sulphide or crystallized zinc is used as a base. The glow is caused chiefly by the bombardment of minute particles to which the zinc is subjected in the presence of radium, and it is necessary to have the zinc sulphide of great purity. The largest of the domestic producers has its mines in Paradox valley, Colorado. The ore is hauled to the railroad, a distance of 58 miles, by six-horse wagons, and from there is carried by rail to a plant in Orange, N. J. The reduction process is a complicated one of chemical separation and elimination. After passing through scores of vats, strainers, compressors, evaporators and the like, about eight carloads of ore have been reduced to less than a thimbleful of radium. Considerable quantities of uranium and vanadium are a by-product of the process.

CONVENTION OF THE MASTER BOILER MAKERS

Welding Firebox Sheets; Steam Pressure and Staybolt Breakage; Handholes vs. Washout Plugs

THE twelfth annual convention of the Master Boiler Makers' Association opened at the Curtis Hotel, Minneapolis, Minn., at 10 a. m., Tuesday, May 25. About 250 members were present at the opening session. The opening address was given by Hon. J. E. Meyers, mayor of Minneapolis, who welcomed the association to the city.

Following this William Schlafge, mechanical manager of the Erie Railroad, spoke of the necessity of organization in the industries, in order that productive efficiency might be increased. The duty of all boiler makers, and particularly the foremen, is to hasten the replacement of power equipment in the country by carrying on the good work which has in the past marked their efforts. During the war the principles of conservation of labor and of materials were applied with remarkable results. Machine equipment was adopted wherever possible to aid production; in other words, every effort was made to obtain a maximum result with a minimum expenditure of time and labor. The same principles must be applied to a higher degree now to carry the nation through

ness. Under the head of miscellaneous business it was voted to consider the invitation of Section III—Mechanical, American Railroad Association, for the Master Boiler Makers' Association to become a member of the organization.

Wednesday Session

The opening address at the Wednesday session was made by J. M. Hall, assistant chief inspector, Bureau of Locomotive Inspection of the Interstate Commerce Commission, on the causes of boiler failures. Lantern slides of disastrous locomotive explosions were exhibited. The accidents illustrated the more usual contributory causes, and in each case these were quite apparent. Low water, corrosion of plates, bad welding of seams, formation of scale in the water glass and gage cock plugs have all increased the total of locomotive disasters. Mention was made of experiments conducted by the chief inspector's office on the relative accuracy of the gage cock and water glass in indicating the true height of water in a boiler. The conclusion reached, after testing

J. B. Tate (Penn.)
President

First Vice-President

Thomas Lewis (L. V.)
Second Vice-President

the present economic crisis without undue hardship. Turning from their constructive duties, Mr. Schlafge spoke of the responsibilities that superintendents and all others in positions of authority have toward the men under them, in instructing them in their work and understanding their requirements. All radical tendencies must be stamped out and the sad experiences of labor in European countries prevented.

The president of the association, John B. Tate, delivered his address on power units of the future. The engineering departments of all roads must provide for more powerful locomotives—engines capable of hauling 150 cars of 150 tons each. In the present freight congestion this need for greater power has been well demonstrated. Stationary boiler design must also be improved, so that the operating efficiency may be increased and the cost of upkeep diminished. Because of the increasing tendency toward the electrification of roads, the size and efficiency of power plant units must be increased. During this reconstruction period the men who hold the responsibilities of supervision in the shops must act at all times in such a manner that decisions are entirely fair and impartial.

The remainder of the Tuesday session was taken up with reports of the secretary and the treasurer and routine busi-

ness. Under the head of miscellaneous business it was voted to consider the invitation of Section III—Mechanical, American Railroad Association, for the Master Boiler Makers' Association to become a member of the organization.

W. H. Bremner, president of the Minneapolis & St. Louis, impressed on the members of the association the necessity for the best workmanship and inspection to keep the present equipment of the railroads at 100 per cent efficiency, for although replacements have been commenced it will be many months before many old locomotives will be eliminated. The railroads depend not on any one individual or group to maintain the standards, but upon every man in the organization, no matter what his duties may be. The same loyalty must be shown to the private companies now as while the roads were under federal control, for the nation's welfare is absolutely dependent on the service of the railroads, which is being well demonstrated at the present time.

After the conclusion of this talk the remainder of the

Wednesday session was devoted to the discussion of papers submitted by members of the association.

Relative Advantages of Handhole Plates and Washout Plugs

In the absence of a report from the entire committee on this subject, the secretary read the personal report of Charles P. Patrick, chairman of the committee.

The question as understood means, what is the best washout opening device to tighten under pressure? This question involves other considerations which must be met. Accidents, expense and terminal delays to locomotives are to be considered with the subject.

The best device to overcome leakage when the boiler is under pressure is a good-order brass plug having 12 threads to the inch and a taper of $\frac{3}{4}$ in. to the foot. These plugs must be full in size, made of good material and have four full, good-order continuous threads at least in the sheet. If these conditions are maintained there will be but little chance of material leakage, and if leakages occur there is little or no trouble or danger in tightening a good-order plug properly applied, which has from some cause or other not been made tight while the boiler was empty.

We cannot provide against neglect of sheets or plugs which cause failures and accidents. These conditions are controlled by the boiler inspectors and men in charge of the work. If the threads on a plug are bad, or the plug allowed to be used

plug. As to accidents chargeable to these plugs we have the following record from the Bureau of Locomotive Inspection: "We have 69,000 locomotives coming under this department. During preceding years the accidents from arch tube and washout plugs consisted of

13 in 1912	17 in 1916
20 in 1913	8 in 1917
21 in 1914	14 in 1918
16 in 1915	30 in 1919

making a total of 139 accidents from all causes during the last eight years, or an average of 17.3 per year. We will assume 18 accidents per year.

"About 40 per cent of these locomotives, or 27,600, are equipped with arch tubes, and the average number of plugs in each boiler is 25. For the entire lot of engines this gives 690,000 plugs. The remaining 41,400 locomotives are without arch tube plugs; therefore have eight less, or 17 plugs per boiler, giving a total of 703,800 plugs, and a grand total of 1,393,800 plugs.

"Some water conditions necessitate the removal of plugs only once a month, while the other extreme is reached in bad water districts where as many as 10 removals a month are made. However, to be on the safe side we will take an average of two washouts a month, which means 33,451,200 washout plugs removed each year. As before stated, we have an average of 18 accidents per year, or one accident for every 1,858,177 plugs removed.

T. P. Madden (Mo. Pa.)
Third Vice-President

E. W. Young (C. M. & St. P.)
Fourth Vice-President

H. D. Vought
Secretary

after it gets a shoulder by which it is temporarily frozen tight, or the sheet allowed to grow thin to the extent that it does not contain sufficient threads to hold the plug, or the threads bruised and battered so a plug will not tighten, an accident or engine failure may occur.

Also the brass screwed washout plug is the most economical washout opening device in use today, and there are no other removable attachments to the boiler that give less trouble or cause fewer accidents.

Discussion

Although handhole plates have been used in some cases without undue trouble, it seemed to be the consensus of opinion that a plug of good design made of brass or steel is far superior, and most of the roads in the country eliminated handhole plates many years ago. All members agreed on the standard of 12 threads per inch, but the taper used varied from $\frac{3}{4}$ in. to $1\frac{1}{4}$ in. per foot, the results, however, differing but slightly. It is possible that plugs having the greater taper are less liable to have a shoulder form, which shortens their period of usefulness.

There are no more complete data on a locomotive device in the records of the bureau than on the service of the washout

"There is really no reason whatever to be alarmed about accidents from washout plugs. They are the safest device I know of on a locomotive boiler, considering how often they are handled.

"And it is also, in my opinion, the cheapest device for stopping up a hole in a boiler which has to be unstopped and restopped from one to ten times a month."

Tensile Strength of Firebox Steel

On the question of whether the best results may be obtained from firebox steel having a tensile strength from 48,000 to 58,000 lb. per sq. in., or from 55,000 to 65,000 lb. per sq. in., the committee has endeavored to make the report on the subject as brief as possible. In gathering this information we find there is a very slight difference of opinion, or rather a slight difference in the specifications of the various railroads, for firebox steel.

The members of the committee have given considerable attention to the care of locomotive boilers, including the study of failures of firebox sheets.

In general, firebox sheets fail in one of two ways:

- (1) Gradual Failure: The sheet may have a good many

small cracks, which are mostly in a vertical direction. These cracks are thickest, radiating out from the staybolts and frequently run from one staybolt to another in the same vertical row, but never between staybolts horizontally. These cracks are almost always on the fire side and at times extend through the thickness of the sheet, first going through next to the staybolts. Such sheets are almost always accompanied with more or less corrugation, and the cracked and corrugated condition is almost always confined to the lower half of the sheet.

(2) Sudden Failure or Rupture: The sheets may fail by a single crack or rupture from a foot to several feet long. In bad cases the crack may extend from the mud ring to the crown sheets, but ordinarily the cracks are confined to the lower half of the sheet, extending upward from the mud ring or from a few inches above it, and it is always near the middle of the side sheet longitudinally. Such sheets may show no corrugations and may show very little if any other defects.

The failures of the first kind are of gradual formation, but those of the second class occur suddenly.

The records on file of one of the largest railroads in the United States show that between the years 1886 and 1913, 115,000 tons of boiler and firebox steel were used on locomotive boilers, and they do not have any record of any failure that resulted in injury to persons or loss of life due to the character of the material.

This same railroad in 1892 specified and adopted firebox steel with a tensile strength of 55,000 to 65,000 lb. per sq. in., and they are using the same grade today.

It is the opinion of the committee that the life of the firebox sheets does not entirely depend on the specifications or tensile strength of the material, but rather on the care and treatment to which the plates are subject; for instance, the washing of boilers with cold water before the boiler is properly cooled down; second, using the injectors when active steam production is not going on.

In conclusion, from the best information this committee was able to obtain, firebox steel with a tensile strength of 55,000 to 65,000 lb. per sq. in. gives the best results.

However, we would also add that it is our experience that by suitable treatment of water supplies, a proper arrangement for delivering feedwater into the boilers and proper methods of caring for boilers in the enginehouses and elsewhere, long life can be expected with most any grade of firebox steel.

The report is signed by W. J. Murphy, chairman; J. F. Ferestrum and Lewis Eberle.

Discussion

Opinion seemed about equally divided on the desirable tensile strength for firebox steel. Good results have been obtained with steel from 48,000 to 58,000 lb. per square inch, as well as from the higher strength of 55,000 to 65,000 lb. per square inch. It seems to be true that if the staybolts are properly applied along the fire line, crown sheet failures will be prevented. In any case the strength of steel or the carbon content have little to do with failures so long as the material is within the 48,000 to 65,000 lb. per square inch limit.

Effect of Steam Pressures on Staybolt Breakage

On the subject of superheating and reducing steam pressures in locomotive boilers and their effect on staybolt breakage, the committee submitted the following report:

The compiled data taken from six different territories or districts where the service, water condition, etc., differ largely and steam pressure is about the same, are given.

The chart shows there is no doubt that the superheater and reduction of steam pressure of boilers from 220 to 195 lb. pressure will decrease the staybolt breakage.

We have also compared 10 locomotives previously operated

as saturated without brick arch. These locomotives were later equipped with a superheater and brick arch, and the pressure remained the same—205 lb.

The comparison shows considerably less staybolt breakage. (While this paper is not on the brick arch, we consider they are co-related and have some bearing on the subject.) The reduced breakage of staybolts is accounted for along these lines: The brick arch acts as an indicator, making the proper

DATA ON STAYBOLT BREAKAGE COVERING PERIOD OF FIVE YEARS

District number	Number of locos.	Steam pressure	Total broken	Bolts broken per year	Bolts broken per engine per year
Superheater.....	5	185 to 200	127	25.4	5.08
Saturated.....	5	220	514	102.8	20.56

Saturated.....	5	220	1,610	322	64.4
Superheater.....	5	185	432	86.4	17.28
Saturated.....	5	220	470	94	18.8
Superheater.....	1	185 to 200	71		
Saturated.....	5	220	358	71.6	14.32

All engines involved are Pacific type.

handling of the boiler compulsory. If the boiler is blown down too soon arch tubes will be distorted. Saving the arch tubes also saves the staybolts.

Our records show that superheating and reducing of steam pressure of boilers result in a reduction of staybolt breakage.

The report is signed by T. L. Mallam, chairman; F. A. Mayer and E. J. Sweeney.

Discussion

An individual report on this subject was submitted by T. L. Mallam, chairman of the report committee.

"The New York Central Railroad, in connection with the Pennsylvania, during 1910 made two elaborate series of tests, and the results obtained showed that superheater locomotives decreased the demand on the boiler from 25 to 35 per cent; that is to say, the boilers of the superheater locomotives have to make considerably less steam than the boilers of the other type. This is, of course, due to the fact that less superheated steam, with its greater heat content, is needed for a given power.

"In line with the results of these tests and my own experience, I contend that superheated boilers do not break as many bolts as boilers not superheated. We have in service on our road four O. G. style fireboxes that are not superheated. These four engines carry 200-lb. per square inch pressure, whereas all the others carry 180-lb. pressure. We find that more staybolts are broken in these four engines than in any eight superheaters.

"There is a question in my mind whether the lesser staybolt breakage on our superheaters is the result of the lower boiler pressure or whether it is the result of other conditions caused by superheat, design and service. As just mentioned, I think the superheater boilers do not have to make as much steam as the saturated steam boilers and therefore do not have to be worked as hard as the latter, with the result that firebox sheets are not punished as badly. The lower boiler pressures of a superheater may help, but I am of the opinion that the greater advantage to staybolts and boiler maintenance conditions from superheat is that with it an engine can be more easily fired and the steam maintained more uniformly.

"I believe everyone appreciates the fact that staybolts are caused to break by expansion and contraction, which again causes the inside and outside sheets to move with relation to each other. The harder and more irregularly the boiler is forced, the greater will be such movement and the greater the staybolt strain. The lower the factor of safety in the design, the greater becomes the chance for staybolt breakage with this strain."

The early part of the discussion seemed to indicate that

the mere act of decreasing the steam pressure by superheating to obtain the same power as with saturated steam would decrease the breakage of staybolts. However, the problem is not quite as simple, for staybolt breakage depends on a variety of independent factors. The steam must, of course, be considered, but so also must the type of service, the general topography of the country in which an engine operates, the quality of the water used, and above all the state of repair of the locomotive. To gain even an approximate comparison between superheated locomotives and those utilizing saturated steam, engines of the same type in the same sort of service and the same condition of repair must be used. The nearest approach to such a comparison came from a representative of the Georgia Railroad, in whose charge are eight locomotives fulfilling the above conditions, four of which are superheaters and the other four use saturated steam. From accurate records of the staybolt breakage on these eight machines there does not seem to be a bit of difference. The final conclusion reached is that the design of a locomotive and its service and care have all to do with staybolt breakage.

Cinder Hopper on Bottom of Smoke Arch

From inquiries and observations made, the committee finds that the use of a cinder hopper on the bottom of the smoke arch is quite varied. There are roads that have some of their engines equipped with a hopper, and others not so equipped, and their performance is also varied; some engines with the hopper as well as those without it clean themselves satisfactorily and steam well, while other engines of the same class and type, having the same design and adjustment of front-end appliance set alike, do not perform as well, accumulating such an amount of cinders in the front end that it is necessary to clean them out while on the road and away from the terminal.

The committee is aware of the fact that with some grades of coal the front end fills up to a greater extent than with other kinds, and to facilitate the removal of cinders the hopper is a convenience, if not a necessity. However, its use or non-use depends largely on local conditions, kind of fuel and grade of coal used. We incline to the opinion that it is not necessary to maintain the hopper on oil-burning nor on coal-burning engines that have front-end draft appliances so designed, fitted and adjusted that they will clean themselves without danger of throwing sparks of such size and glow that they cause fires on the road.

Our inquiries further indicate that the foregoing also applies equally as well to the second part of the subject, "On what size locomotives should it be maintained?" and that the use of the cinder hopper is about evenly divided between the larger and smaller classes of engines on the various railroads.

In regard to the third question of the subject, viz., "Which is the better design to overcome air leaks?" we find that there are a number of different designs used by the various roads. Some have hoppers with a double nozzle lengthwise of the smoke arch, others a double nozzle transverse with the arch, the cover held in place by a bolt and spring between the nozzle, while on others a single nozzle with the cover hinged so it will drop down, or one that opens to one side, is used. Again, others have the single nozzle hopper, the cover being of wedge shape. As it is of great importance to keep the front end as free as possible from air leaks, it is our opinion that the single nozzle hopper with the cover plate fastened on each side is a better design.

The report is signed by Frank H. Davison, chairman. Thomas J. Reddy and John L. Welk.

Discussion

The need of the cinder hopper on the bottom of the smoke arch has long since been eliminated by most roads. In its place a standard form of non-adjustable, self-cleaning front end has been applied. In some instances a patch is riveted

under the smoke arch and a two-inch washout plug arranged to take care of any leakage from the pipes or superheater tubes.

Flanging of Firebox Sheets on the Flange Press

The committee reported that the flanging of firebox sheets on a flanging press is not detrimental. It is a matter of the proper heating of the material.

Cold flanging can be successfully employed on round heads and straight sides of flue and door sheets in all types of fireboxes.

The report is signed by Robert C. Gibson, chairman.

Thursday Session

A short talk was given by A. H. Kipp, mechanical superintendent of the Soo Line, on the duties of the members of the association to the country. Following this the discussion of papers was resumed.

Electric and Oxy-Acetylene Welding of Firebox Sheets

In the absence of a report, Prof. A. S. Kinsey, in charge of welding and shop practice at Stevens Institute of Technology, gave a general survey of the present standing of autogenous welding and the future prospects of its recognition as a permissible process of boiler construction.

Professor Kinsey had just been present at the St. Louis meeting of the American Society of Mechanical Engineers, at which a prominent insurance company requested that the Boiler Code Committee, of which Professor Kinsey is a member, allow the use of autogenous welding in stationary heating boilers generating steam up to 15-lb. pressure. The Boiler Code Committee is considering this petition seriously and will probably report favorably on it. In connection with this subject the A. S. M. E. Boiler Code Committee has appointed a sub-committee to investigate the matter of welding seams in boilers and pressure vessels with a similar committee from the American Welding Society.

Forge welding has been allowed a rating of 52 per cent, or a permissible load of 52 per cent of the strength of the metal, by insurance companies. Although autogenous welding is not recognized as yet, there is no reason why fusion welding cannot be made very nearly as strong as forge welding. As a matter of fact, an increase in the rating of forge welding from 52 to 75 per cent is now being considered by the A. S. M. E. If every one interested in advancing the process is united, first of all, in demanding the best welds possible in the shops where the process is used and then in advocating its adoption and recognition by the insurance companies and the A. S. M. E., there can be little doubt of the outcome.

From consultations with A. G. Pack, chief inspector of the Bureau of Locomotive Inspection, and from extensive examinations of defective welds taken from exploded boilers, Professor Kinsey stated that they were some of the worst welds he had ever examined and that they had done a great deal to retard the advance of the process.

The development of autogenous or better fusion welding has nearly reached the point where it is possible to weld manganese steel frogs on rails. Firebox plates can be welded as safely as they can be riveted by either the electric arc or acetylene torch. Any weld may be easily made to lose its strength by burning or oxidizing the metal, and this is the greatest defect to be combated in the operation of welding.

Two rules should be followed in welding. The grain of the metal should be so refined as to come back to its original size and, in the case of steel, the weld should be annealed. When recognized by the A. S. M. E., this requirement for annealing will probably be inserted in the rules for permissible welding procedure.

At the St. Louis meeting of the A. S. M. E. the safe-ending of boiler tubes was discussed at one of the Boiler Code Committee sessions, and the records were consulted to determine

if welding were allowable in this case. It was found that it is permissible to weld the safe ends of tubes in fire tube boilers but not in water tubes, which means that locomotives may use it in this connection.

Discussion

The criticisms brought out at the last convention have served their purpose in arousing the interest of all members of the association, and no doubt the fewer accidents from the letting go of welded seams may be due to the closer supervision of all welding in railroad shops. However, if the reports of the Bureau of Locomotive Inspection continue to show any disastrous explosions from the failure of welded seams, it will be a difficult matter to obtain an early official recognition of the process.

A short paper on the procedure used in electric arc welding was given by one of the members.

On the Santa Fe the welding departments of all shops are required to send test specimens of their work to the laboratories to be tested to destruction. The seams are reinforced about 20 per cent and when pulled average about 83 per cent, which is about what is obtained with riveted joints. One instance was cited of 29 specimens taken out of plates after being in service 4½ years, which tested 71 per cent.

As on all other questions, opinion was divided. Certain members advocated great caution in adopting the process, particularly where human life depends on the quality of the work. So long as there is a doubt as to the safety of a seam, and certainly until disasters from weak seams have stopped, it is well to avoid the extensive application of autogenous welding. The discussion turned from welded seams to the welding of flues. In certain sections of the country it was found that electrically welded superheater flues cracked, while smaller tubes were not found to do this. In still other districts leaks are found in both superheater and smaller flues. In bad water districts, scale forms in pockets around the flue end, and by preventing the cooling effect of the water, permits the heat to crack the tube. This applies to the side sheet, under the arch as well as where the heat is intense. When staybolts are calked where they enter the side sheets, pin cracks are started if the water does not circulate properly. Flues should be prossered in bad water districts.

Where welds have been found sound in good water districts, a few months with hard water have only been necessary to allow the formation of cracks. The conclusion seemed to be that in good water districts welded flues remained tight, while bad water tended to hasten the formation of cracks in safe ends.

The subject of welded patches was barely touched upon without any definite decision as to their use.

Best Style Grate for Bituminous Coal

No report was submitted by the committee, but a brief outline of the use of the box grate was presented by William Stinsky. In the course of the discussion it was stated that the time is rapidly approaching when the dump grate will be eliminated from both ends of the firebox. The best results have been obtained with box grates having a width of nine inches. If a dump grate is used it must be kept from under the flues, for if used in this position all sorts of leakage and trouble result.

The draft opening in the ashpan was brought up for discussion, and the opinion seemed to be general that at least 15 per cent of the grate area should be opened in the pan to obtain complete combustion of fuel. Even with the opening in the pan, sufficient flues must be installed to carry off the gases. Side openings and center openings have been tried, and netting has been used in the pan, all bringing about good results where used to fill certain operating requirements.

Box grates up to 11 in. wide have been tried and minimum openings of 18 per cent, with varying degrees of success. The

standard, however, seems to be a nine-inch grate and a 15 per cent ashpan opening.

Following this the annual election of officers was held.

Officers for 1920-1921

President, Charles P. Patrick, Wilson Welding Repair Company; first vice-president, Thomas Lewis, Lehigh Valley; second vice-president, T. P. Madden, Missouri Pacific; third vice-president, E. W. Young, Chicago, Milwaukee & St. Paul; fourth vice-president, Frank Gray, Chicago & Alton; fifth vice-president, Thomas F. Powers, Chicago & North Western; secretary, Harry D. Vought; treasurer, W. H. Laugbridge, Hocking Valley.

Executive board for one year: L. M. Stewart, Atlantic Coast Line; John F. Raps, Illinois Central; John Harthill, New York Central. For two years: W. J. Murphy, Pennsylvania Railroad; Harry F. Weldin, Pennsylvania Railroad; E. J. Reardon, Interstate Commerce Commission. Three years: B. F. Sarver, Pennsylvania Lines; George Austin, Santa Fe; H. J. Wandberg, Chicago, Milwaukee & St. Paul.

DRILLING RECORDS MADE AT ATLANTIC CITY

Drilling demonstrations with Cleveland milled high speed drills were conducted during the annual June convention of the American Railroad Association, Sections III and VI, at Atlantic City. Several records were made in these tests and it is reported that records made in 1911 were completely shattered. On June 15 and 16, milled high speed drills were forced through cast iron at the rate of 6 ft. per minute and through machinery steel at the rate of 2½ ft. per minute. Details of speed, feed, etc., are given below.

Material	Dia. of drill	R.p.m.	Feed in. per rev.	Number of inches drilled	Vol. lb. removed
3 in. cast iron.....	1 in.	720	.100	9 in.	14.74
3 in. mchy. steel.....	1 in.	600	.050	3 in.	6.60
3 in. cast iron.....	1¼ in.	720	.100	15 in.	23.01
3 in. mchy. steel.....	1¼ in.	500	.040	3 in.	7.00

It is evident that the above records could not be recommended for commercial shop practice as few, if any, shops would have the press equipment or power to duplicate them. For example, in making the record in cast iron with a 1-in. drill, a feed of .100 in. per revolution and speed of 720 R. P. M. were used. Good shop practice would indicate a speed no greater than 267 R. P. M. and a feed of .015 in. per revolution. In the tests shown above, both the feed and speed exceeded normal practice. The same statement applies to the record in machinery steel. Demonstrations, like the above, show the tremendous reserve in the modern high speed milled twist drill. Stock drills were used in the tests and the drills were driven by a Foote-Burt heavy duty drill press.

Additional drilling tests were conducted in open hearth chrome nickel steel using Hercules high speed drills made by the Whitman & Barnes Manufacturing Company, the power being furnished by a 6 ft. American radial drill. The results of these tests showed conclusively that hard and tough alloy steels can be drilled on a production basis and economically. The chemical analysis of the steel showed .50 per cent carbon, .90 per cent chromium, 1.00 per cent nickel and .75 per cent manganese. Holes 3 in. deep were drilled in nine seconds with 1 in., 1¼ in. and 1½ in. drills attaining a penetration of 1 in. every three seconds. The following is a summary of the data secured in these tests:

Material	Dia. of drill	R. p. m.	Feed in. per rev.	Time per hole	Average No. holes per grinding
3 in. alloy steel..	1 in.	500	.040 in.	9 sec.	32
3 in. alloy steel..	1¼ in.	500	.040 in.	9 sec.	24
3 in. alloy steel..	1¼ in.	500	.040 in.	9 sec.	27
3 in. alloy steel..	1½ in.	500	.029 in.	12½ sec.	29
3 in. alloy steel..	2 in.	206	.040 in.	22 sec.	27
3 in. alloy steel..	2¼ in.	206	.022 in.	40 sec.	12

Right Line Radial Drilling Machine

RIGHT line radial drilling machines built in either full universal or plain types and with five-foot or six-foot swing have been developed and placed on the market recently by the Niles-Bement-Pond Company, New York. These right line radials embody somewhat radical changes from the usual type of radial drill. The drive has been simplified so that a high percentage of the driving power is delivered to the spindle. A general view of the machine, Fig. 1, indicates the entire absence of belts and the reduction of driving gears to a minimum. A feature of the new drill

tegral at the top and bottom, the arm saddle being mounted between them. The motor is mounted on the back of the arm saddle and drives the spindle through a single horizontal shaft running between the column members.

Since the column is not stationary, but rotates with the arm, it has been possible to place the metal to the best advantage in the form of a patented beam section. Bending stresses in the column are always in the direction for which this section is designed. Another advantage of this type of column is that it permits the use of vee tracks at the front and back for guiding the arm saddle. When clamped by means of a wedge connection on these tracks, the arm and column form a rigid unit. Instantaneous clamping of the column to the pedestal is obtained by means of a motor operated device shown in Fig. 4. This device is both simple and convenient in operation and the clamp is engaged and disengaged by throwing a switch located on the control head. It is not necessary for the operator to leave his working position. A lever for clamping by hand also is provided. The electric clamp is operated by a small motor with one wheel, the mechanism being self-adjusting. The arm is especially easy to swing, its entire weight being supported on a ball bearing at the bottom of the column. When clamped, a broad metal to metal contact makes the column and pedestal practically one piece.

The maximum resistance to drilling pressure is secured by a specially designed arm cross section as shown in Fig. 5. With the upper narrow guide for the saddle and the lower bearing set in a plane back of the front surface, the driving shaft is brought closer to the spindle and a greater depth is secured from the front to the back of the arm. Under heavy drilling strains, this design tends to eliminate the deflection of the column and arm structure.

The arm is raised and lowered by power from the driving motor, the mechanism being engaged by throwing the clutch lever located on the driving gear box. The machine is started

Fig. 1—General View of Niles-Bement-Pond Right Line Radial Drill

which adds to the rigidity of the machine and simplicity of drive is the patented double column arrangement, a cross section of which is shown in Fig. 2. This arrangement allows for direct drive from the motor to the spindle through the double column also shown in Fig. 3. The column is a single casting formed of two box section members cast in-

back of the arm. Under heavy drilling strains, this design tends to eliminate the deflection of the column and arm structure.

The arm is raised and lowered by power from the driving motor, the mechanism being engaged by throwing the clutch lever located on the driving gear box. The machine is started

and stopped by means of a controller handle on the control head. The elevating and clamping mechanisms are interlocking and cannot be engaged simultaneously with resultant damage to the machine. An automatic stop to pre-

Only four driving gears and one double faced pinion are used between the motor and spindle and the driving mechanism has been further simplified by eliminating friction clutches for spindle reverse and tapping operations. The spindle is quickly and accurately reversed by reversing the

Fig. 2—Cross Section of Double Column Arrangement

vent damage or accident to the machine should the operator carelessly run the arm to the limit of its travel in either direction has been provided. This device also stops the arm in case an obstruction is met in lowering. The elevating

Fig. 4—View of Electric Column Clamp

motor through the controller lever. The spindle counterweight is geared to the spindle and supported at its center of gravity to eliminate friction. A depth gage with an automatic feed trip is provided for drilling to a desired depth. Rapid hand traverse of the spindle is secured by means of

Fig. 3—The Main Driving Shaft Passes Between the Two Columns

screw is hung at the top of the column on a friction ring and when the spindle or arm meets an obstruction in lowering, the elevating screw is lifted and turns freely, thus stopping the arm.

Fig. 5—Cross Section of Arm Designed for Maximum Torsional Strength

a lever which, when pulled down, engages the power feed. An ample range of speeds is provided and there are eight positive geared feeds changed by means of a graduated disc.

Fine hand feed for the spindle also is provided. The drill head is easily moved along the arm by means of a hand wheel conveniently located at the front of the head. On universal machines, this hand wheel can be swung back out of the way when the spindle is to be swiveled.

For direct current drive, a 10 hp., four to one variable speed motor is required. For alternating current drive, a gear box is included to give the additional speeds required. In either case, the motor is provided with an automatic brake for stopping quickly in tapping operations.

Recording Instruments for Switchers

A DESCRIPTION of a model *K* recording instrument for locomotives in road service was given on page 306 of the May *Railway Mechanical Engineer* and the model *L* Loco-Recorder, described in this article, is designed for use on switchers. The instrument furnishes

a clear and complete performance record of switch engines, and affords information, the vital importance of which has long been appreciated. The record shows: (1) The time in hours and minutes that the engine is idle; (2) the time in hours and minutes that the engine is working; (3) the

Record of Switchers for Four Hours Reading from Right to Left

of these lines and their relation to the minute marks show the rate of speed. Broken lines indicate reverses. When the engine is idle the pencil remains stationary and makes a straight horizontal line on the tape. The total

distance in miles actually covered; (4) the speed at which the engine is operated at any point or at any time.

An odometer automatically records the exact mileage, registering every 35 ft. and can be set back to zero at the end of every day, week or month as desired. To conform to the service required of it, the recorder operates on a time

A Locked Metallic Case Prevents Tampering With the Mechanism

Internal Mechanism of the Loco-Recorder

idle time is thus easily calculated. An actual reproduction of the record of a switch engine for four hours, is shown in the illustration. This record shows that the switcher went ahead an eighth of a mile, stood still for two minutes, reversed and ran three-eighths of a mile at a speed of nearly eight miles an hour. It then stood still for

It then stood still for

two minutes, reversed and ran a quarter of a mile in five minutes, reversed again and ran an eighth of a mile, stood still for seven minutes, reversed again and ran 150 yards, reversed again after standing a little more than a minute and ran a quarter of a mile in two minutes and a half. After standing for four minutes the engine again reversed and ran three-quarters of a mile in eight minutes. It then made three short runs and three reverses, with three stops of about four minutes each, and was idle for 27 minutes, after which it ran a mile and an eighth at a maximum speed of half a mile in two minutes and was idle for 20 minutes. Knowledge of yard conditions makes the record a complete

story of the day's work, down to the smallest detail, and it is an easy matter to compute the idle, and working time and the service performed.

Since speed indications on a switcher are not required, the instrument can be attached to any convenient part of the locomotive and is not necessarily placed in the cab. The water-tight cover, which has to be raised for the removal and insertion of tapes, is securely locked, as shown in the illustration, and this prevents any interference with the recording mechanism. Loco-Recorders for both switchers and road locomotives are manufactured by the Speedograph Corporation, Newark, N. J.

Cutting and Welding Torch for Shop Use

CERTAIN inherent characteristics should be possessed by cutting and welding torches intended for shop service. Among these characteristics may be mentioned simplicity, ruggedness, low cost of maintenance and safety in operation. In addition, the torch should be light, well balanced and economical. With the desirability and importance of these characteristics well in mind, the A. G. A. Railway Light & Signal Company, Elizabeth, New Jersey, has recently developed a line of oxy-acetylene cutting and welding torches known as the A. G. A. torches. These torches have been thoroughly tested under severe service conditions in railway shops, navy yards and other industrial plants and are reported to have given uniformly satisfactory service.

Mixture of the gases is accomplished in the tips which are of the one piece type, thus eliminating the possibility of losing either the tip or mixer parts. The high pressure valve of the cutting torch is operated by the thumb in such a way that a single motion will open or close it. This makes alterations in pressure possible with a minimum loss of time. A welding table is furnished with the torches, and reference to the line showing thickness of metal in sixteenths of an inch, will indicate the number of tip to be used; also, the proper gas and oxygen pressures.

The standard manufacturer's torch of this make weighs only 28 ounces and is not tiresome to hold. It has been demonstrated that the effect of a heavy torch on the quality and quantity of an operator's work is most important. Not

A. G. A. Cutting and Welding Torch

only is it necessary that a torch be light in weight, but it must be well balanced in order not to cause unnecessary fatigue to the operator. With hoses attached, the A. G. A. torches balance at a point in the center of the grip. The grips are made of a ventilated, non-conducting material, oval in cross section and therefore easy to control.

Gas connections are indicated by distinctive colors as advocated by the Bureau of Construction and Repair of the Navy Department, the valve handles being plainly marked "Oxygen" and "Acetylene." All inflammable gas cylinders are painted red and the oxygen cylinders, black. This color scheme being carried out in the hoses, there is little danger of wrong connections and accidental explosions.

While not intended to be abused, torches are often subjected to rough usage either through accident or careless-

ness. The torches, illustrated, are of rugged construction and the tips, being internally threaded, are protected against damage. The heads and valve bodies are made of drop forged bronze to insure durability, the gas head tubes being of seamless drawn brass, which is difficult to spring. Nuts on which there is a considerable amount of wear are made of phosphorous brass.

Low cost of maintenance is secured by making the torches of interchangeable parts, assembled with mechanical metal to metal joints. There are no brass, soldered or welded joints to be made. Referring to the view showing a cross

Cross Section of Torch Head

section of the torch head, it will be evident that the gas head tubes are tightened in the valve body by taper bronze ferrules forced tightly about the tubes by the hexagon head nuts. The torches can be completely disassembled by the operator and then reassembled without difficulty; hence, a damaged part does not necessitate factory repairs or scrapping.

Economy of gas consumption can be secured only by establishing and maintaining a true neutral flame. Either an oxidizing or carbonizing flame indicates an excess of free oxygen or acetylene, respectively, damaging the quality of the welds and causing uneconomical torch welds. Complete mixing is accomplished in these torches by forcing the oxygen and acetylene together at equal pressures, passing the mixture through a restricted conical orifice which sets up a turbulent effect in the stream of gas and at the same time creating a velocity which prohibits back flash. The mixed gases emerge from this orifice and proceed down the tip, the turbulent effect decreasing as the mixture becomes more

and more thorough. It is not possible to thoroughly mix gases by allowing them to run together. They must be forced together and agitated until the mixing is completed. A glance at the cross sectional view will indicate how this thorough

mixing is accomplished in A. G. A. torches. Economy in gas consumption, freedom from back fire and elimination of the possibility of self-destruction, by internal burning, are secured by the design of these torches.

Facilitating the Removal of Side Rods

BY MAKING both main and side rods, also link motion rods, symmetrical above and below the true central plane, a method was described on page 105 of the February, 1917, *Railway Mechanical Engineer*, which makes it possible to get along with a much smaller stock of rods. The idea is to make the rod with two oil cups, one

Front Side Rod With Oil Cups Set at an Angle

on each side, and by this construction, the rod can be used on either side of the locomotive, thereby reducing the number of rods required to be carried in stock by one-half.

From the fact that only one-half as many rods as of the

standard form of construction need be carried in stock, the saving in costs of material on hand is considerable. The rods can be made up and properly constructed for the same work as the standard rods, no change in counterweights of the engine being necessary.

An additional feature carried out in the design of front side rods is shown in the illustration. Usually when the front section of a pair of side rods is to be removed, the engine is set with the crank pin on the bottom quarter and, in this position, the oil cup on the front side rod section extends above the bottom guide and cannot be removed without jacking up the engine. To obviate this difficulty, the side rod illustrated was designed and patented by three employees of the Delaware, Lackawanna & Western at Scranton, Pa., Charles E. Weitaw, William R. Owens and H. R. Jones. As indicated, the oil cups are set at an angle so that the upper corner of the oil cup extends only slightly above the crank pin collar. A considerable saving of effort will be effected by the use of this rod inasmuch as it can be removed easily without jacking up the engine.

Open Side Planer Proves a Flexible Unit

A MACHINE that is equally well adapted to perform small planing operations on irregular shapes either in roundhouses or back shops, has been developed recently by the Automatic Machine Company, Bridgeport, Conn. The machine referred to is the Coulter open side

being held with equal facility and ample room being provided for the use of table fixtures. The clear view afforded makes it easy to adjust the cutting tool to lay-out lines on either end of the work, both ends being equally visible. Irregular shapes of a larger size than could pass between two

Coulter Openside Crank Planer With 24-In. Stroke

View Showing Motor Drive and Rigid Arm Construction

planer, which has already proved its value for this kind of work.

Railway shop men are waking up to the advantages afforded by open side planer construction, among which is maximum ease in setting up the work, large or small pieces

housings are easily machined on the open side machine.

Another advantage of this particular open side planer is the fact that it bridges the gap between planer and shaper construction. The convenience and speed of the shaper is combined with the accuracy and increased capacity of the

planer. Floor space is saved and ease of operation combined with high cutting speeds and feeds assures maximum output. Horizontal, vertical and angular power feed is provided, with graduated collars on the feed screw and the swivel plate. A rack and pinion raises and lowers the balanced cross rail. Sliding gears allow four speeds for each length of the table stroke.

The large supporting base forms a rigid foundation for the machine and other features tending to provide increased rigidity and accurate work are, the long, wide gibbed table provided with three tee slots and three squaring slots, the large vertical column supporting the cross rail, the length and breadth of the sliding surface on the vertical column

and cross rail and the long vertical down feed slide. The bull gear, hub bearing and crank are of rugged construction and the design provides a quick return stroke to the table. Reference to the illustration showing the arrangement for motor drive indicates the compact drive arrangement. A short continuous belt gives excellent results in service, although a silent chain drive can be used if desired.

The open side counterweighted cross rail is securely held in any position by three clamps; two handles on the front are tightened by a half turn and there is a hand wheel on the rear of the arm. The design of the cross rail and braces, all in one piece, reduces the possibility of spring and provides a rugged construction.

An Easily Applied Automatic Fire Door

PNEUMATICALLY operated fire doors are sometimes troublesome to apply because of the additional room required for opening. The back head of a modern locomotive has little unused space and to avoid interference with the various devices and their connections, that are necessary for efficient and safe locomotive operation, is often difficult. The Franklin No. 9 fire door was designed to permit of application where space is limited. It takes approximately the same space as an ordinary hand operated swing door and can be applied without relocating other boiler accessories. It is simple in construction and has few wearing parts. It consists of a door frame, semi-rotating door plates and operating cylinder with a foot pedal to provide power operation, and a hand grip for manual operation. A latch is provided to hold the door open in three different positions; wide open and two smoke notch positions. Air pressure both

In operation, pressure on the pedal admits air to the operating cylinder and the piston moves upward, transmitting motion to the upper door to rotate it around its pivots. This door is connected by a link to the rocker at the top of the frame, which in turn is connected by a link to the lower door

Franklin No. 9 Automatic Fire Door Closed

opens and closes the door; therefore it is positive in its movements. The movement of the upper door plate is actuated by the power cylinder, the motion being transmitted to the lower door plate by links. In opening, the door plates telescope inside the door frame providing full unobstructed opening for firing. This telescopic action forms the opening without taking space on the backhead outside of the door frame. The door plates rotate on pin bearings on either side.

Automatic Fire Door In Full Open Position

so that the movement of the upper plate is transmitted to the lower plate to rotate it on pivots to the open position. At the top of the cylinder a small poppet valve is opened by the upward movement of the piston; this admits air to the cylinder and cushions the upward stroke of the piston at the same time the links are assuming a position which reduces the leverage on the doors and brings them to the full open position without slam or shock.

When pressure is removed from the foot pedal, air is exhausted from the lower end of the cylinder and the air in the upper end forces the piston downward and starts the doors toward the closed position. After the piston has traveled about one-third of its movement the valve in the top of the cylinder seats, cutting off the air supply entirely. At this time the top door has traveled to a point where its weight is effective to raise the lower door. This, with the trapped air in the top of the cylinder, brings the doors to the closed position. As the piston travels downward the lower end of the cylinder acts as a dash pot and prevents slamming.

The Times Trade Supplement (London) is authority for the statement that owing to the shortage of raw materials, Belgian manufacturers have been obliged to refuse large orders for railway material, locomotives and wagons needed for South America.

A seat for a brakeman is being provided on freight locomotives in Canada, all engines to be equipped by May 1, 1921. This action has been taken on the recommendation of the Railway Association of Canada, following a request from the brakemen's brotherhood.

The Bureau of Valuation of the Interstate Commerce Commission held an informal meeting with representatives of carriers at Chicago on April 29 and 30. Engineers from roads in all sections of the country were present to discuss the progress made by the bureau in the preparation of valuation reports.

After a spirited debate resolutions were adopted in favor of government ownership of the railroads at the annual convention of the American Federation of Labor at Montreal, Que., on June 17, by a vote of 578 delegates, representing 29,159 votes in favor of the resolution and 8,349 against it. During the debate President Gompers took the floor against the passing of the resolution.

It was stated in the last report of the Indian Railways that 112 locomotives were burning oil fuel. It is anticipated that, owing to the increased output of oil from the Persian concessions of the Anglo-Persian Oil Company, the use of oil fuel on the railways of Western India will in the near future be extended. Tests conducted on this system on 20 engines fitted with different types of burners showed that the work done by one ton of oil would require 1.8 tons of coal.

Four French railroads announce that they will dismiss the men from their large shops and will have car and locomotive repairs done by contract. This is the gist of a cable despatch of May 17. The four roads are the State, the Orleans, the Paris, Lyons & Mediterranean and the Southern. The reason given for this action is that the shops were hotbeds of radicalism and their output was low. Ten thousand men will be released. Repairs will be done by private corporations able to discharge unwilling workers. The railroads are restricted by law in dealing with their employees.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, east of the Mississippi river, \$3.00 a year; west of Mississippi river and Canada, \$4.00 a year; elsewhere \$5.00, or £1 5s. 0d. a year. Foreign subscriptions may be paid through our London office, 34 Victoria Street, S. W. 1., in £ s. d. Single copy, 30 cents.

WE GUARANTEE, that of this issue 10,100 copies were printed; that of these 10,100 copies, 9,420 were mailed to regular paid subscribers, 9 were provided for counter and news company sales, 256 were mailed to advertisers, 32 were mailed to employees and correspondents, and 383 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 84,050, an average of 12,007 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

The Order of Railroad Station Agents, at its biennial convention recently held at Pittsburgh, Pa., voted, after discussions lasting three days, to eliminate the word "strike" from its constitution. This action was taken because of the organization's faith in the provisions of the Transportation Act for the handling of employees' grievances. The organization also voted to remove its headquarters from Boston, Mass., to Chicago. So far as can be ascertained at the present time, this is the first organization of the kind, composed of railroad employees, which has, because of this faith, eliminated strike clauses from its constitution.

Pupils of John Marshall high school machine shop classes (Richmond, Va.), under the supervision of their instructors, built a 22-in. modern engine lathe during shop classes in exactly seven months and three days from the time it was started and the machine is now in operation in the school machine shop, where it will become a permanent addition to the present equipment. Every detail of the machine was designed, drawn and constructed by the pupils themselves. It is valued at \$1,800, is 7 ft. 6 in. in length and weighs about 2,500 lb. It will swing a piece of work 22¼ in. in diameter and is 46 in. between centers. It has cross and longitudinal feeds, adjustable compound rest, and is capable of cutting screw threads from one to 52 threads per inch. The construction of the machine involved nearly every principle that should be taught in modern machine shop practice, according to the instructors of the class.

Wage Award Announcement Set for July 20

The United States Railroad Labor Board issued a statement on June 25, through its chairman, Judge R. M. Barton, to the effect that a decision on the billion dollar wage demands of organized railway employees, which the board has had under consideration since April 20, will be announced on or possibly before July 20. The public hearings on these demands terminated on June 2 and since that time the Labor Board has been in executive session.

Inspection of Freight Equipment

In the March issue of the *Railway Mechanical Engineer* on page 150, the location of the brake shaft on drop end low side gondolas, drop and high side gondolas, tank cars and caboose cars without platforms, was given as on the end of

the car to the left of the center and not more than 22 in. from the center. This is an error, as the safety appliance act requires the brake staff to be located on the end of the car to the left of the center, but does not specify any limiting dimension.

A. S. M. E. Railroad Section

In accordance with certain changes in the organization of the American Society of Mechanical Engineers, allowing for the formation of professional sections, a Railroad Section has recently been organized. The following officers have been elected: Chairman, Edwin B. Katte, chief engineer electric traction, New York Central; vice-chairman, George W. Rink, assistant superintendent of motive power, Central Railroad of New Jersey; other members of the executive committee, C. W. Huntington, president, Virginian Railway; Harry B. Oatley, Locomotive Superheater Company, and W. H. Winterrowd, chief mechanical engineer, Canadian Pacific Railway. It is understood that the Railroad Section will arrange for a special part in the program at the annual meeting of the society in New York next December.

Cost of Running a Railroad One Day

The second step in the reclamation campaign which has been instituted on the Chicago, Milwaukee & St. Paul, as noted in the *Railway Mechanical Engineer* for April, page 247, has been taken, in the form of a poster showing the daily expenditures on the road for fuel, lumber, etc. According to the poster, which is printed in brilliant red, 36 cents is paid for materials and supplies out of every dollar received by the company. It is also stated that every 24 hours the road spends:

\$45,800 for fuel for locomotives.	\$1,620 for station supplies.
13,700 for lumber and timber.	1,510 for shop machinery and tools.
10,200 for enginehouse expense.	1,320 for lubricants and supplies for locomotives.
8,660 for train supplies.	300 for electric light bulbs.
8,400 for ties.	
1,750 for stationery and printing.	

The committee asks for the co-operation of the employees to increase efficiency, save material and prevent waste in order to reduce the costs noted in the above items.

Changes in Rules of Interchange

V. R. Hawthorne, secretary, American Railroad Association, Section III, announces that rule 3, section k, of the rules of interchange, 1919, has been modified to read "No car will be accepted in interchange unless properly equipped with United States safety appliances, or United States safety appliances, standard, except cars moving home on car service orders, for equipping with safety appliances. Cars will not be accepted from owner at any time unless equipped with United States safety appliances or United States safety appliances, standard."

Also that rule 3, section o, is modified to read "Cars built after November 1, 1920, will not be accepted in interchange unless equipped with 6-in. by 8-in. shank A.R.A. standard type D couplers."

Working Conditions in the Prussian State Railroad Repair Shops

The Charlottenburger Neue Zeit gives some interesting facts and figures about the working conditions in the repair shops of the former Prussian State Railroad. In consequence of the demobilizing act the number of working men employed by the repair shops was increased from 70,000 to 160,000. Notwithstanding this great increase the shops are unable to meet the demands made upon them. The decrease of efficiency of the repair shops is one of the most serious problems facing the railroad management. The fact that efficiency has gone down although the railroad management spent 447,000,000 marks in 1918, and 110,000,000 marks

in 1919, for the improvement of equipment, and although the materials needed, especially copper, have been delivered in the meantime in sufficient quantities, tends to show the serious aspect the situation has taken. In the summer of 1919, the repair shops turned out 750 repaired locomotives monthly. In November, 1919, only 650 were repaired and in January, 1920, only 520 locomotives were repaired.

A. I. E. E. and A. S. M. E. to Combine Forces

Plans have been made for holding a series of joint meetings of the American Institute of Electrical Engineers and the American Society of Mechanical Engineers. The object of the joint meetings is to secure a strong program and, as the war interrupted interest in normal engineering progress, to create a new interest in old problems which now require revised consideration under existing conditions. In general the subjects selected for these meetings will come under the following classifications: Marine engineering, engineering education, industrial installations, power generation, steam railroad electrification and industrial relations. It is intended to hold the first meeting in October, on a date to be announced later.

Railway Rolling Stock for New Zealand Government

The New Zealand Government has announced, writes Consul General Alfred A. Winslow from Auckland on April 10, as noted in Commerce Reports, that the railway department will expend about \$8,516,375 for the purchase of rolling stock for government railroads of this Dominion, covering 65 locomotives, 35 passenger cars, 12 brake vans, and 4,092 freight cars.

It is announced that the government proposes to invite tenders in England for the manufacture of 25 large locomotives and 2,500 freight cars; and tenders in New Zealand for the building of 1,000 freight cars to be delivered in the shortest possible time.

In addition to the above the department is providing for the building of 20 locomotives, 35 passenger cars, 12 brake vans, and 592 freight cars in its own shops at the different centers. Twenty locomotives are now being built under contract by A. & G. Price, all to be delivered within five years.

Rolling stock is greatly needed, since the government railroads are not able to meet the increasing amount of freight offered for transportation, and the accumulation of all classes of traffic throughout the Dominion is very great.

It would seem, adds Mr. Winslow, that it would pay American interests to investigate this opening, for it is not probable that British manufacturers will be able to deliver these locomotives and cars in time to relieve the freight situation within a reasonable time, and rolling stock allotted for construction in this dominion cannot be supplied within the next four or five years unless labor conditions change very materially. In any event much of the material to be used in the construction of this rolling stock in New Zealand must come from outside and will call for hardware, car-building accessories, and certain lines of timber.

Interested parties should correspond with the Minister of Railways covering the general contracts, and with A. & G. Price at Thames or Auckland relative to supplies for the 20 locomotives they are building.

MEETINGS AND CONVENTIONS

Traveling Engineers' Association.—The next convention of the Traveling Engineers' Association will be held in Chicago, commencing September 14, 1920.

Master Car and Locomotive Painters' Association.—This association will hold its next convention on September 14 to 16, inclusive, at the New American House, Hanover street, Boston, Mass.

PERSONAL MENTION

GENERAL

American Railway Tool Foremen's Association.—The next convention of this association will be held at the Hotel Sherman, Chicago, on September 1 to 3, 1920, inclusive.

Master Blacksmiths' Association.—The International Railway Master Blacksmiths' Association will hold its next annual convention at the Hotel Statler, Detroit, Mich., on August 17, 18 and 19. The secretary of the association is A. L. Woodworth, Lima, Ohio. The president of the supply Men's Organization is H. D. Kelley, 1427 Western avenue, N. S., Pittsburgh, Pa.

American Gear Manufacturers' Association.—At a meeting of the executive committee on May 1, held at the close of the convention of this association, the following officers were elected: F. W. Sinram, president; H. E. Eberhardt, vice-president, and Frank D. Hamlin, secretary and treasurer. Messrs. Sinram and Hamlin have served as president and secretary, respectively, since the organization of the American Gear Manufacturers' Association three years ago, during which time it has grown from eight to eighty member companies. One of the chief features of the convention was the discussion of standardization as it affects the gear industry, an entire day being devoted to this subject.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.—J. P. Murphy, N. Y. C., Collinwood, Ohio.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. B. Baker, Terminal Railroad, St. Louis, Mo.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, 1145 E. Marquette Road, Chicago. Convention September 1-3, Hotel Sherman, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & W. Station, Chicago.
- CANADIAN RAILWAY CLUB.—W. A. Booth, 131 Charron St., Montreal, Que. Meetings second Tuesday in month, except June, July and August.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 North Pine Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koencke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings second Friday in January, March, May and September and second Thursday in November, Hotel Statler, Buffalo, N. Y.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—J. C. Keene, Decatur, Ill.
- CINCINNATI RAILWAY CLUB.—H. Boutet, 101 Carew Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, B. & O., Lima, O. Convention August 17-19, Hotel Statler, Detroit, Mich.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 702 East 51st St., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention Sept. 7-10, 1920, Hotel Sherman, Chicago.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B. & M., Reading, Mass. Convention September 14-16, New American House, Boston, Mass.
- NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Meetings second Tuesday in month, except June, July, August and September.
- NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings third Friday in month, except June, July and August, 29 W. 39th St., New York.
- NIAGARA FRONTIER CAR MENS' ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings second Thursday in month, alternately in San Francisco and Oakland.
- RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Friday in month, except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.—J. B. Frauenthal, Union Station, St. Louis, Mo. Meetings second Friday in month, except June, July and August.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y. Convention September 14, Chicago.
- WESTERN RAILWAY CLUB.—J. M. Byrne, 916 West 78th St., Chicago. Meetings third Monday in month, except June, July and August.

G. L. LAMBETH, superintendent of motive power and car equipment, of the Mobile & Ohio, has moved his headquarters from Mobile, Ala., to St. Louis, Mo.

G. C. NICHOLS, superintendent of motor power and equipment of the Alabama, Tennessee & Northern, with headquarters at York, Ala., has been promoted to superintendent, with the same headquarters, and his authority has been extended over the maintenance of way and transportation departments.

JOHN C. DAVIDSON has been appointed engineer of electric traction of the Norfolk & Western, with office at Bluefield, W. Va. Mr. Davidson's early experience in railroad

J. C. Davidson

work was obtained in Scotland where he completed his apprenticeship in the locomotive department of the Great North of Scotland Railway. After completing his apprenticeship he was employed in the drafting room and on material inspection and testing. From 1902 to 1906 he was employed by the British Westinghouse Company as assistant engineer on design of rolling stock and electrical equipment for the Mersey Railway and the Metropolitan

Railway electrifications. Mr. Davidson then took up work in the United States and was employed for four years as assistant engineer by the Pennsylvania Tunnel & Terminal Railroad. In this connection he worked on the electrification of the New York tunnels, specializing in the development of locomotive equipment. He entered the employ of Gibbs & Hill, consulting engineers when the firm was organized. Here he was employed as engineer on projects and designs, appraisals and reports for heavy main line electrification and was engineer in charge of the Norfolk & Western electrification. He resigned from this work to accept his present position.

G. G. YEOMANS, general purchasing agent of the New York, New Haven & Hartford, with headquarters at New Haven, Conn., has been appointed special assistant to the president, handling all matters assigned relating to materials and supplies.

C. B. YOUNG, manager of the Test Section of the United States Railroad Administration, has been reappointed mechanical engineer on the Chicago, Burlington & Quincy, with headquarters at Chicago.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

EDWARD G. BOWIE, who has been appointed division master mechanic of the Brownville division of the Canadian Pacific, with headquarters at Brownville, Me., as announced in last month's issue, was born on August 20, 1892, at Winnipeg, Man. He was educated in Aberdeen High School

and began railroad work in May, 1907, as a machinist apprentice, after which he worked as a machinist until July, 1915. He was then a dynamometer car operator on the Eastern lines until October, 1915, assistant locomotive foreman and locomotive foreman until June, 1918, being located respectively at Outremont, Que., Sherbrooke, Que., and Smith's Falls, Ont. From June, 1918, to April, 1920, he was general foreman in charge of the Canadian Pacific shops at McAdam, N. B., and on the latter date received his appointment as division master mechanic at Brownville, Me.

JAMES DAVIS has been appointed road foreman of engines on the Southern Pacific, with headquarters at Sparks, Nev., succeeding S. A. Canady, who has been assigned to other duties.

CHARLES W. MCGUIRK, assistant master mechanic of the Delaware, Lackawanna & Western at Scranton, Pa., has been appointed master mechanic of the Delaware & Hudson at Carbondale, Pa., effective July 1. Mr. McGuirk was born in Norfolk, Conn., on June 3, 1872, and was educated in St. John's School, Schenectady, N. Y. He served a four-year machinist apprenticeship at the Oneonta shops of the Delaware & Hudson. Subsequently he was employed as engine-house and shop foreman on the New York, Ontario & Western, the Lehigh Valley and the Boston & Maine. In 1906 he accepted a position as foreman of the new engine-house of the Delaware & Hudson at Oneonta, N. Y., and was promoted to general foreman of the locomotive and car departments in 1908, remaining with the latter road until April, 1912. At that time he went to the Delaware, Lackawanna & Western as general roundhouse foreman at Scranton, Pa., and about four years ago was promoted to the position of assistant master mechanic.

H. W. SASSER has been appointed superintendent of shops of the Erie at Galion, Ohio, succeeding A. J. Davis, transferred.

CAR DEPARTMENT

J. A. DEPPE, assistant master car builder of the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee, Wis., has been appointed supervisor of the freight car department, with the same headquarters, succeeding C. G. Juneau.

C. G. JUNEAU has been appointed acting master car builder of the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee, Wis., succeeding L. K. Sillcox. Mr. Juneau was born on December 12, 1874, at Milwaukee and received a public school education. He served a blacksmith apprenticeship in the car and locomotive departments of the Chicago, Milwaukee & St. Paul, which he completed on October 1, 1899, after which he was employed for about a year as a tool dresser by the Strobel Structure Company, Chicago, returning to the Chicago, Milwaukee & St. Paul on July 21, 1900, working in the car department. On February 12, 1906, he was appointed assistant foreman of the blacksmith shop. On March 1, 1918, he was appointed general foreman of the car blacksmith department for the entire system and on June 1, 1918, was made general supervisor of the freight car department, including the blacksmith department. In March, 1920, he was placed in charge of the Milwaukee terminal and shop district and on June 1, 1920, received his recent appointment.

HENRY MARSH, formerly passenger car foreman of the Chicago & North Western, with headquarters at Chicago, has been appointed district master car builder of the same road, with office at Winona, Minn.

A. S. STERNBERG, general foreman of the Belt Railroad of Chicago, with headquarters at Chicago, Ill., has been

made master car builder, the position of general foreman being abolished.

C. L. WALKER has been appointed master car repairer at the Los Angeles, Cal., general shops of the Southern Pacific.

SHOP AND ENGINEHOUSE

HARRY G. BECKER, who was recently appointed shop superintendent of the Delaware & Hudson at Colonie, N. Y., as announced in the June issue, has been engaged in railroad work since 1901, at which time he entered the employ of the Chicago, Burlington & Quincy at Beardstown, Ill., as a machinist apprentice. He remained with that road as a machinist and draftsman until 1909, when he accepted a position as shop demonstrator at the Sayre shops of the Lehigh Valley. He was later machine foreman and general erecting foreman until 1915, when he left the service of that road to accept the position of general foreman of the Delaware & Hudson at Colonie, New York, which he held until his recent promotion to the position of shop superintendent.

PURCHASING AND STOREKEEPING

L. J. AHLERING, traveling storekeeper on the Chicago & Eastern Illinois, with headquarters at Danville, Ill., has been promoted to general storekeeper, with the same headquarters, succeeding W. T. Bissell, who has resigned.

R. B. BANNERMAN has been appointed storekeeper on the Chicago division of the Minneapolis, St. Paul & Sault Ste. Marie, with headquarters at Fond du Lac, Wis.

H. S. BURR, superintendent of stores of the Erie Railroad at Meadville, Pa., has been appointed general superintendent of stores, with headquarters in New York.

E. A. ERNST, chief clerk in the office of the district storekeeper of the Chicago, Rock Island & Pacific at Horton, Kan., has been promoted to district storekeeper at Shawnee, Okla., succeeding E. W. Morris, deceased.

W. L. HUNKER, district storekeeper of the Chicago, Rock Island & Pacific, at Chicago, has been transferred to Silvis, Ill., succeeding J. C. Kirk.

J. C. KIRK, district storekeeper on the Chicago, Rock Island & Pacific, with headquarters at Silvis, Ill., has been promoted to assistant general storekeeper, with the same headquarters.

J. B. NOYES has been appointed storekeeper on the Soo division of the Minneapolis, St. Paul & Sault Ste. Marie, with headquarters at Minneapolis, Minn.

N. M. RICE, vice-president of the Pierce Oil Corporation, St. Louis, Mo., has been appointed general purchasing agent of the New York, New Haven & Hartford, succeeding G. G. Yeomans.

J. H. SWEENEY, storekeeper for the Erie at Meadville, Pa., has been appointed superintendent of stores at Meadville, succeeding H. S. Burr.

E. L. ZINK, chief clerk in the office of the district storekeeper of the Chicago, Rock Island & Pacific at Silvis, Ill., has been promoted to district storekeeper, at Chicago.

OBITUARY

GEORGE H. HAZELTON, formerly division superintendent of motive power of the New York Central & Hudson River at Albany, died on June 10. Mr. Hazelton was in the service of the New York Central, or associated lines, for more than 53 years, starting on the Rome, Watertown & Ogdensburg. He was superintendent of motive power of that road when it was taken over by the New York Central, and was made division superintendent of motive power at Albany.

During recent years he has been assigned to special duties, retiring last fall, when he was 70 years of age. After his retirement, however, he was called back into the service for special work.

COLONEL W. D. MANN, designer of the "boudoir sleeping car," used extensively in Europe, and formerly for a number of years in this country (on the Cincinnati, New Orleans & Texas Pacific), died at his home in Morristown, N. J., on May 17, at the age of 81 years.

WILSON WORSDELL, formerly chief mechanical engineer of the North Eastern Railway of England, died recently at South Ascot, Berkshire, England, his death being reported in the Railway Gazette (London) of April 16. Mr. Worsdell was a pupil at the Altoona shops of the Pennsylvania Railroad when he was a young man and began his railway service in England on the London & North Western. He was at the head of the mechanical department of the North Eastern from 1890 to 1910. During this period he built about 1,000 locomotives and several thousand cars. He introduced high capacity freight cars. He had been president of the Association of Railway Locomotive Engineers, and for several years past had been a director of the Westinghouse Brake Company.

FREDERICK O. ROBINSON, for many years chief clerk to the superintendent of motive power of the Chesapeake & Ohio, and secretary of the Richmond Railroad Club, died on March

F. O. Robinson

26, 1920, at a hospital in Richmond, Va. He had been in failing health for several years. Mr. Robinson was born in Farmington, N. H., on August 20, 1852, and began his railroad career with the Indianapolis & St. Louis in 1872, serving as telegraph operator for two years. He was later employed by the Indianapolis, Peru & Chicago for 16 years as chief clerk to the master mechanic. He served in the capacity of telegraph operator and clerk for the Wabash and as chief clerk to the general superintendent of the Lake Erie & Western. In 1892 he entered the service of the Chesapeake & Ohio as clerk to the purchasing agent, being later promoted to chief clerk of that department, in which capacity he served until 1895 when he was appointed chief motive power clerk, holding this position for 16 years under the late W. S. Morris and James F. Walsh. In 1911 he was appointed equipment clerk of the Chesapeake & Ohio, which position he filled until recently. On the organization of the Richmond Railroad Club Mr. Robinson was elected secretary-treasurer and held that office until his death.

HIGH WAGES AND LESSENER EFFICIENCY still support high prices. There are as many workingmen in the country today as there were a year ago, or two years ago. But their output is not so great and their wages much higher. Production costs are therefore increased. Strikes, holidays, vacations and diminished output per man all add to the price of goods, and hold up the price level. Labor inefficiency and sabotage are to be found in the transportation question, affecting distribution and hindering an orderly recession of prices.—*The Wall Street Journal*.

SUPPLY TRADE NOTES

G. E. Lemmerich, railroad layout engineer for the Austin Company, Cleveland, Ohio, died on April 25, of heart failure.

A. B. Konsberg, dealer in railway equipment, has moved his offices from 226 South La Salle street, Chicago, to 40 North Dearborn street.

John Scullin, chairman of the board of the Scullin Steel Company, St. Louis, Mo., died in St. Luke's Hospital, St. Louis, on May 28, at the age of 83.

W. G. Cook, manager of the Chicago office of the Garlock Packing Company, Palmyra, N. Y., has been transferred and is now manager of its Philadelphia, Pa., office.

W. Searle Rose, district manager of W. L. Brubaker & Brothers, manufacturers of taps, dies and reamers, 50 Church street, New York, has been appointed sales manager.

F. J. Foley, general sales agent, and E. McCormick, assistant to the president of the Railway Steel Spring Company, have been elected vice-presidents of the company.

The Cleveland office of the Electric Storage Battery Company, Philadelphia, Pa., has been moved from the Citizens building to Chester avenue and East Twenty-fourth street.

The Buda Company, Harvey, Ill., recently completed the construction of an additional foundry, for casting small engine parts. The building is of iron, 160 ft. wide, with concrete foundation.

The Rich Tool Company, Chicago, announces that the Garlock-Walker Machinery Company, Ltd., with offices in Toronto, Montreal and Winnipeg, has been appointed its exclusive agent for Canada.

W. F. Myer has been appointed directing transmission engineer, industrial bearings division, of the Hyatt Roller Bearing Company, New York. Mr. Myer is in charge of the sale of Hyatt line shaft roller bearings.

The R. W. Young Manufacturing Company, electric turntable tractors, electric hoists and cranes, announces its removal from 80 East Jackson boulevard, to the Harris Trust building, 111 West Monroe street, Chicago.

A. C. Johnston, chief engineer of the Link Belt Company, Chicago, has been promoted to vice-president and resident general manager of the Chicago plant, succeeding Prentiss L. Coonley, who is devoting his time to other duties.

Ernest S. Jubell, in charge of materials at the plant of the Haskell & Barker Car Company, Michigan City, Ind., has been appointed general superintendent of the Union Railway Equipment Company, with headquarters at Hammond, Ind.

The George P. Ladd Company, Pittsburgh, Pa., manufacturer of water tube boilers, has opened a district sales office at 528 McCormick building, Chicago, in charge of W. M. McKinstrey, formerly district manager for the Page Boiler Company, Chicago.

The Union Railway Equipment Company, Chicago, has purchased a tract of land at Hammond, Ind., and is now erecting shops for the manufacture of its railroad freight car specialties. When completed the plant will total an investment of approximately \$1,500,000.

George F. Smardon, who served as secretary and assistant to Carl R. Gray, director of operation, United States

Railroad Administration, during federal control, has become associated with the Anchor Packing Company, Philadelphia, as railway representative for eastern railroads.

B. G. Prytz has resigned as president of the SKF Industries, Inc., having been elected managing director of the parent company, with headquarters at Gothenburg, Sweden. F. B. Kirkbride, vice-president since the organization of the company, was elected president to succeed Mr. Prytz.

The Electric Controller & Manufacturing Company, Cleveland, Ohio, has opened a branch office in Boston, Mass., at 49 Federal street. The new office is in charge of M. D. Goodman. An office has also been opened in St. Louis, Mo., at 208 North Broadway, in charge of R. J. Ehrhart.

The Rome Iron Mills, Inc., New York, manufacturer of solid and hollow locomotive staybolt and engine bolt iron, announces the appointment of A. M. Castle & Company as its western representative. The latter company has offices in the principal western cities, with warehouses at Chicago and Seattle.

The Chicago Flexible Shaft Company, Chicago, has opened an office in the Railway Exchange building, St. Louis, Mo., in order to render more efficient service and distribution in the southwest territory. The office is in charge of Otto Bersch, formerly connected with the Brown Instrument Company, and Jack Stroman.

DeWitt V. D. Reiley, vice-president of the Davis-Bournonville Company, Jersey City, N. J., has been elected president, succeeding Augustine Davis, who resigned last November. Charles B. Wortham, treasurer of the company since its organization, was elected vice-president and William G. McCune secretary and treasurer.

Whitfield P. Pressinger, first vice-president and general manager of the Chicago Pneumatic Tool Company, with headquarters in New York, died recently at the Roosevelt Hospital in New York following an operation. Mr. Pressinger was born at New York on September 27, 1871. He received a public school education and shortly after beginning work he entered the employ of the company in whose service he rose to the rank he occupied at the time of his death. Mr. Pressinger was the author of "Advances of Compressed Air," which has been translated into several languages. Besides being a member of many other clubs, he was a member of the New York Railroad Club and the American Society of Civil Engineers. He also served for nine years with Company A, Seventh Regiment.

W. P. Pressinger

J. H. Kuhns, manager of the railroad department of the Republic Rubber Company, has been elected vice-president of the Union Asbestos & Rubber Company, Chicago, which company has been appointed the western railroad sales agent for the Republic Rubber Company. His headquarters will be at 231 South Wells street, Chicago.

The Page Steel & Wire Company has removed its New York offices from 30 Church street, to the offices of the American Chain Company, with which it has been consolidated, in the Grand Central Terminal, New York. The

Chicago office of the company has been moved from 29 South La Salle street to 208 South La Salle street.

William Oesterlein, president of the Oesterlein Machine Company, Cincinnati, Ohio, died at his home on May 10. Shortly after coming to Cincinnati about 50 years ago he started a machine tool shop in a small way and is reputed to have built the first milling machine in Cincinnati. He was one of the founders of the machine tool industry in that city.

Allan E. Goodhue, who was managing director of the Chicago Pneumatic Tool Company's English subsidiary, the Consolidated Pneumatic Tool Company, London, England, since May 1, 1919, also director of European sales for the Chicago Pneumatic Tool Company, New York, has been elected vice-president in charge of sales of the latter company, with headquarters at New York. Mr. Goodhue was formerly for a number of years connected with the sales department of the Midvale Steel Company and the Midvale Steel & Ordnance Company in Philadelphia, Chicago and Boston, and left that company in March, 1918, to

A. E. Goodhue

enter the service of the United States government. He was assistant manager of the steel and raw material section, Production Division of the Emergency Fleet Corporation, until January, 1919, when he became connected with the Chicago Pneumatic Tool Company.

The Superior Screw & Bolt Company has opened new offices at 810 Hippodrome building, Cleveland. The company, which was recently incorporated, with a capital of \$500,000, intends to manufacture a complete line of tap screws and bolts. Officers of the new corporation are: president, M. T. Jones; vice-president, M. J. Riley; secretary and treasurer, W. J. Hayes.

The Norton Company, Worcester, Mass., has opened a branch office for the grinding machine division at 324 Bulletin building, under the direction of Paul Hoffman, district manager. The establishment of this branch office will in no way affect the distribution of Norton grinding wheels; these will be handled as in the past by Powell, Clouds & Co., 602 Arch street, Philadelphia.

K-G Welding & Cutting Company, 556 West Thirty-fourth street, New York, manufacturers of welding and cutting apparatus, has opened a sales office in order to accommodate its western trade, at 12-14 East Harrison street, Chicago, where a complete line of welding and cutting apparatus will be carried. William McCarthy, who has been in charge of the railroad service department, has been appointed western sales manager.

The Greenfield Tap & Die Corporation, Greenfield, Mass., has acquired all of the common stock of the Lincoln Twist Drill Company, Taunton, Mass. This company manufactures twist drills, reamers and milling cutters. These, added to the products of the Greenfield Tap & Die Corporation, give it a complete line of small tools. Edward Blake, Jr., formerly sales manager of Wells Brothers Company, is vice-president and general manager of the Lincoln Twist Drill Company.

Due to the retirement of A. F. Stillman from active interest in the management of The Watson-Stillman Company, New York, several changes in the personnel have been made. E. A. Stillman remains as president and also has full supervision of the sales. Carl Wigtel, chief engineer, has been elected vice-president, J. D. Brocks, treasurer, and A. Parker Nevin, secretary; LeRoy T. Brown has been appointed works manager, J. W. Delano, assistant works manager, and W. H. Martin, purchasing agent.

Charles Blizard, third vice-president of the Electric Storage Battery Company, died on June 12. He was born at Stevens Point, Wis., in 1864, and was educated in the east,

C. Blizard

graduating from the Brooklyn Polytechnic Institute. In October, 1893, he became associated with the Electric Storage Battery Company and was in the service of the company a total of 27 years. He was at first manager of the New York office and in 1900 he was moved to the home office in Philadelphia in charge of sales. In April, 1906, he was made third vice-president, which position he retained until the time of his death. Mr.

Blizard was an active member of the Electric Vehicle Association, serving on various committees, and he later continued his activities in the electric vehicle section of the National Electric Light Association. He was also a member of the board of governors and chairman of the finance committee of the Associated Manufacturers of Electrical Supplies.

The Reed-Prentice Company, Becker Milling Machine Company and Whitcomb-Blaisdell Machine Tool Company have opened a sales office at the Grand Central Palace for handling sales in the New York territory. The office will be in charge of P. K. Dayton, formerly connected with the Niles-Bement-Pond Company and Manning, Maxwell & Moore, assisted by P. A. Dyer, formerly of the General Electric Company. A store has also been opened in Cleveland at 408 Frankfort avenue, in charge of C. A. Severin, formerly of the Cleveland Tool & Supply Company, assisted by Charles Brandhill.

Frank A. DeWolff, assistant locomotive superintendent of the Cuban Central, has joined the forces of the International Railway Supply Company, 30 Church street, New York, as its traveling representative. Mr. DeWolff was engaged in active railroad work for the past 22 years, having begun as a machinist apprentice in Mexico. He subsequently served as machinist, power house engineer, locomotive fireman, engineman and superintendent of shops. From July, 1916, to January, 1919, he was general master mechanic on the Cuban Central and from the latter date was assistant locomotive superintendent in charge of the locomotive and car departments of the same road.

The personnel of the Elvin Mechanical Stoker Company, New York, is now as follows: John B. Given, president, Albert G. Elvin, vice-president in charge of operation and treasurer; F. H. Elvin, assistant to vice-president in charge of operation; Frank H. Clark, vice-president; Frederick P. Whitaker, secretary; A. B. Fahnestock, chief engineer; H. D. Eckerson, manager of road service. The headquarters of

the company are at 23 West 43rd street, New York. The Elvin stoker has been in operation on the Erie for three years and is now being tested out on the Grand Trunk. A description of this stoker and its use on the Erie was published in the *Railway Mechanical Engineer* for February, 1918, page 103.

Percy M. Brotherhood, senior vice-president of Manning, Maxwell & Moore, Inc., New York, has been appointed executive vice-president with the powers and duties attaching to the office of president, succeeding Alfred J. Babcock, president, who resigned on account of ill health. Mr. Brotherhood has been associated with the company for over 25 years and during recent years has been in charge of its machine tool business. Eugene Maxwell Moore was recently elected vice-president in charge of foreign sales. Henry D. Carlton has been elected a director of the corporation, following his recent election to the office of vice-president in charge of the brass goods sales, succeeding the late John N. Derby. Robert A. Bole, general sales manager of Pittsburgh, has also been elected a director and vice-president.

Edward M. Dart, founder of the E. M. Dart Manufacturing Company, Providence, R. I., died June 5, while at his summer home at Shawomet Beach, R. I. He was born January 19, 1835, in New London, Conn., where he received his schooling, and, after gaining mechanical experience in companies in that city, he entered the employ of Law & Kannon, Providence, R. I., manufacturers of gas piping and fixtures. In 1858 he became connected with the Providence Steam & Gas Pipe Company and later went to the Mason Machine Works, Taunton, Mass. He subsequently worked for the firm of Hudson & Wood and the Perkins Horse Shoe Company, both of Providence. In 1866 he established his own business of manufacturing pipe and fittings, which grew until in 1894 he formed the E. M. Dart Manufacturing Company.

L. Finegan, superintendent of the Mt. Clare shops of the Baltimore & Ohio, has been appointed general manager of the American Flexible Bolt Company, with headquarters at Pittsburgh and Zelenople, Pa. Mr. Finegan was born in California. He began work as a machinist apprentice in Butte, Mont. On the completion of his apprenticeship he entered the employ of the New York Central at Buffalo, and later the General Electric Company and the American Locomotive Company at Schenectady. Leaving the American Locomotive Company he went with the Delaware & Hudson as general foreman. In 1904 he became general foreman of the West Springfield shops of the Boston & Albany Railroad. In 1911 he entered the service of the Baltimore & Ohio as master mechanic at Glenwood, Pa., and was later appointed superintendent of shops at this point. In 1915 he was appointed superintendent of the Mount Clare shops.

George H. Scott, electrical engineer with the O. K. Giant Battery Company, with headquarters at Gary, Ind., has been appointed representative of the Safety Car Heating & Lighting Company, New York, in charge of the Northwestern territory, with headquarters at Chicago. Mr. Scott was born on June 6, 1880, in Pulaski county, Mo., and was educated in the State Normal School. He entered the service of the St. Louis-San Francisco at Springfield, Mo., on February 23, 1899, working in various departments of this road until 1906, when he was appointed foreman electrician with headquarters at St. Louis, Mo. In December, 1907, he was appointed traveling electrician on the Chicago, Rock Island & Pacific, with headquarters at Chicago, and was later promoted to general foreman in the electrical department. He was appointed foreman electrician with the Pullman Company at Cincinnati, Ohio, on June 1, 1910, with which company he was employed until his resignation to become electrical engineer with the O. K. Giant Battery Company.

TRADE PUBLICATIONS

BELT FASTENERS.—The Crescent Belt Fastener Company, New York, has published a new handbook illustrating Crescent belt fasteners in use on many different kinds of belting and under different conditions, and giving full data regarding their use.

EXPANSION JOINTS.—The Griscom-Russell Company New York, has published bulletin No. 1010, an eight-page pamphlet containing specifications for the two types of G-R expansion joints for use on low pressure steam lines to provide for expansion and contraction of the pipe.

BEARING ALLOY.—The Ajax Metal Company, Philadelphia, Pa., is distributing a small leaflet describing the composition of Ajax bull bearing alloy and its advantages as a general purpose lining metal. It is claimed to be not only cheaper than genuine and other tin-base babbitts, but to last longer and run cooler.

CAR JACKS.—Bulletin No. 301, an eight-page pamphlet, is being distributed by the Duff Manufacturing Company, Pittsburgh, Pa., and gives complete information regarding Duff high speed ball bearing jacks of 50 and 35 tons capacity, designed especially for raising heavy freight and passenger cars in railway repair shops.

HEATING SYSTEMS.—The Gold Car Heating & Lighting Company's modern heating and ventilating systems for railway cars are described fully in a 40-page catalogue supplement recently issued. The results of laboratory and service tests made during the past winter of the company's latest type vapor valves are also contained in the supplement.

WATER DISTILLING APPARATUS.—The Barnstead Still & Sterilizer Company, Chicago, has issued a 20-page pamphlet describing and illustrating its line of water purifiers and stills. This includes several types, for commercial use, laboratory and druggist use, as well as for garages and home drinking water supply. The stills are operated by gas, high pressure steam or electricity, as sources of heat.

ARCH TUBE CLEANERS.—A revised catalogue of locomotive arch tube cleaners (W-4) has been issued by the Lagonda Manufacturing Company, Springfield, Ohio. The catalogue goes into the subject of arch tube cleaning and describes the different types of standard cleaners made by this company, giving a description of their general construction and usage. It also illustrates repair parts and covers briefly several other products.

SUPERHEATED STEAM IN YARD ENGINES.—Bulletin No. 10, published by the Locomotive Superheater Company, New York, presents data obtained in tests made of two engines in switching service, one using superheated steam and the other saturated. Three classes of switching work were included in the test. An indicator was used and careful readings were taken, the results showing decidedly superior performance for the superheated locomotive over that using saturated steam. Detailed information of the tests is given in the pamphlet and a comparison of the performance of both locomotives is given in tabular form.

GASOLINE LOCOMOTIVES.—Record No. 95, published by the Baldwin Locomotive Works, Philadelphia, Pa., deals with internal combustion locomotives, weighing from 5 to 25 tons, and adapted to work in contracting operations, plantations, quarries, switching in railroad yards, etc. Various changes and improvements have been made in these locomotives since their introduction and the general principles of

construction are described and illustrated. A table shows the performance, rating and principal dimensions of the standard sizes of Baldwin gasoline locomotives.

BOILER MAKERS' TOOLS.—A new and attractive book which will interest boiler makers has just been published by J. Faessler Mfg. Moberly, Mo. Its 68 pages include a recently developed line of roller expanding and flaring tools for locomotive superheater tubes, locomotive arch tubes, and stationary water tube and marine boiler tubes. Special types of expanders are included for Stirling, B. & W., and Heine boilers. These and other Faessler tools are fully described in detail and illustrated.

MACHINE GUARD HANDBOOK.—A handbook dealing with the subject of machine guards has been compiled for the Consolidated Expanded Metal Companies, Braddock, Pa., and is being issued by that company. It is designed for the use of managers, purchasing agents and guard makers, and contains information regarding the requirements of practical guards, how to obtain suitable guards for any purpose, specifications for letting contracts, what to guard, etc. The booklet contains 44 pages, 4 in. by 7 in., and is illustrated.

MACHINE TOOLS.—Under the title of Gisholt products the Gisholt Machine Company, Madison, Wisconsin, has issued a 24-page booklet in which are illustrated the machine tools manufactured by this company. The illustrations include turret lathes, both hand and automatically operated, vertical boring and turning mills, universal tool grinders and horizontal boring and drilling machines. Several of the illustrations show machines set up for performing specific operations. The tools for use on the turret lathes are also illustrated in detail.

TURRET LATHE PRACTICE.—A reference book on vertical turret lathe practice in railroad shops has been issued by the Bullard Machine Tool Company, Bridgeport, Conn. The book contains 43 pages, 9 in. by 11 in., and is well illustrated. Detailed illustrations and descriptions of methods of tooling pistons, packing rings, air pump cylinders and rings, cylinder heads, cross heads, rod brasses, driving boxes, eccentrics and straps, throttle boxes, crank pin washers, engine truck centers, etc., are given. The book is extremely valuable as a reference for quick, efficient methods of setting up these locomotive parts and performing necessary machine operations.

PRESSED STEEL CARS.—A well arranged and beautifully bound catalog has been issued by the Pressed Steel Car Company, New York. It is comprehensive and well written, containing 290 pages, 9½ in. by 11 in. Clear cut illustrations of the company's products are shown on a scale large enough to indicate details. The first two-page spread shows the company's offices and works both in Pennsylvania and Illinois, and other interesting illustrations show the welfare and educational work carried on for the employees. Beginning on page 14, the various pressed steel cars including box, caboose, coke, flat, gondola, tank cars, etc., are illustrated in detail with general dimensions of the cars and a brief description of their construction. The latter part of the catalog shows the method of handling foreign shipments and includes an interesting picture of a group of 3,000 car operators working under the direction of the Pressed Steel Car Company's erecting engineers in Vladivostok, Siberia. Descriptions and illustrations of the company's specialties such as truck and body bolsters, pressed steel and arch bar trucks, brake beams, carlines, steel storage and agitator tanks, etc., are given. The method of manufacturing chilled iron car wheels is explained and tables of decimal equivalents and conversion tables are shown in the back of the catalog.

With the status of rates established and the wage controversy settled, the fuel problem remains the one thorn in the side of the railroads that promises to harass them relentlessly throughout the coming winter. It is a grave situation when many railroads are not getting sufficient coal to meet current requirements at a time when it is customary to stock for the coming winter, and it is a serious matter when any railroad has to pay over \$20 a ton for locomotive coal. It is time that every mechanical employee took a renewed interest in reducing the fuel bill and in making it possible for his railroad to operate next winter without cutting off many trains from the schedule. Fuel is the pulse of the railroad; almost every operation in the conduct of the railroad, almost every physical feature in its make-up affects directly or indirectly the size of the coal bill. Of those factors which directly affect coal consumption, the condition of the locomotive is of outstanding importance. Mechanical engineers can do many things that will help save coal. One of these is to provide a joint for the outside steam pipes where these intersect the smokebox so that this connection can be kept free from air leaks, as described in an article on this subject appearing in this issue. New locomotives should be built with joints that can be kept tight, old locomotives should be provided with such joints as fast as they go through the shop. The foreman's duty with respect to saving coal is obvious; he is expected and should be required to keep the engines under his jurisdiction in the best condition possible with the facilities at his disposal. Details count for everything in this game and of these none is more important than nozzle size. Only the strictest supervision will eliminate nozzles that are needlessly restricted for one cause or another. Engineers frequently prefer re-

The Fuel Crisis

duced nozzles to insure plenty of steam under all conditions and nozzles reduced are seldom enlarged to an economical diameter, once the cause has been removed. If the roads expect enginemen to do their bit toward saving coal, they must neglect no detail in the upkeep of the locomotive that will make for efficiency.

Some years ago a superintendent of motive power strolling through an important engine terminal spoke of a certain foreman for whom he originally had a high regard. When the man first tackled the job he wore overalls and a jumper. "Now," remarked the superintendent of motive power, "I see that he has discarded the overalls," and added laconically, "When he discards the jumper I think I will have to let him go." Perhaps the superintendent of motive power knew from the way things were going that the foreman was losing his grip on the job and accepted his habit of dress merely as an indication. On the other hand, would the superintendent of motive power have been justified in accepting this incident as proof that the foreman was not making good? It has been alleged that some well-known corporation magnates would judge a man by the clothes he wore. If the young business man must wear good clothes to make an impression and get ahead in the world, must the railroad foreman wear old clothes or a suit of overalls to "stand in" with the superintendent of motive power? It is well enough to say that the matter of dress is at best a superficial question, but many men take the subject quite seriously. These men feel that their character of dress will not only make an impression on their superiors, but will affect the relationship with the men under their supervision.

The man who wears overalls or his oldest and most grease-

duced nozzles to insure plenty of steam under all conditions and nozzles reduced are seldom enlarged to an economical diameter, once the cause has been removed. If the roads expect enginemen to do their bit toward saving coal, they must neglect no detail in the upkeep of the locomotive that will make for efficiency.

Do Clothes Make the Foreman?

Some years ago a superintendent of motive power strolling through an important engine terminal spoke of a certain foreman for whom he originally had a high regard. When the man first tackled the job he wore overalls and a jumper. "Now," remarked the superintendent of motive power, "I see that he has discarded the overalls," and added laconically, "When he discards the jumper I think I will have to let him go." Perhaps the superintendent of motive power knew from the way things were going that the foreman was losing his grip on the job and accepted his habit of dress merely as an indication. On the other hand, would the superintendent of motive power have been justified in accepting this incident as proof that the foreman was not making good? It has been alleged that some well-known corporation magnates would judge a man by the clothes he wore. If the young business man must wear good clothes to make an impression and get ahead in the world, must the railroad foreman wear old clothes or a suit of overalls to "stand in" with the superintendent of motive power? It is well enough to say that the matter of dress is at best a superficial question, but many men take the subject quite seriously. These men feel that their character of dress will not only make an impression on their superiors, but will affect the relationship with the men under their supervision.

The man who wears overalls or his oldest and most grease-

stained suit in order to make an impression on the superintendent is no more deserving of criticism than the man who believes that a silk shirt and neatly creased trousers will command greater respect from the men who are obliged to go about in dirty overalls. The railroad shop or roundhouse is no place to display your particular preference for green or red neckwear, plain or striped hose, and so on; nor is it the foreman's place to banish modest self-respect and grovel in dingy garb in order to make it appear that he has just emerged from the inspection pit when, as a matter of fact, he has been comfortably lounging in the foreman's office. It is suggested that in view of the present high cost of living the shop is a good place to wear out the suit that your wife objects to having you wear downtown. It is further suggested that a moderate display of white linen sets well on any foreman, not so much as a matter of personal taste or even self-respect, but as an indication of the fact that you have your work well organized, that you do not find it necessary to personally inspect every bolt and rivet—in fact, that you are using your head as well as your arms and legs.

The railroad labor organizations profess to be dissatisfied with the award of the Labor Board which granted an increase of 13 cents an hour to the shop crafts. The principal argument advanced by the unions to support their claims for higher wage scales was the advance in the cost of living. It is therefore interesting to analyze the award from that viewpoint. The cost of living at present is variously estimated to be 100 to 115 per cent higher than in 1914. The statistics of the Interstate Commerce Commission for that year are incomplete, but they show that the average daily compensation of machinists in railroad service was \$3.27 and of carpenters \$2.66. The present rates for an eight-hour day are \$6.80 for machinists and \$6.48 for car men, making the increases 108 per cent and 144 per cent, respectively. However, in 1914 many shops were working 10 hours instead of eight and all overtime is included in the wage given in the commission's report, so the actual percentage of increase is greater than shown above.

The statistics for 1915 are more complete and while they include some advances in wages over 1914, they furnish an interesting basis for comparison. The average hourly wages of mechanics in 1915 were as follows: machinists \$0.386, boilermakers \$0.386, blacksmiths \$0.371, car inspectors \$0.232, car repairers \$0.265 and mechanics' helpers and apprentices \$0.226. The present rates, therefore, represent increases in the hourly wage of 120 per cent for mechanics and boilermakers and slightly more for blacksmiths. Helpers now receive 174 per cent more than in 1914, while car repairers and car inspectors have had increases of 202 per cent and 245 per cent, respectively. If the numerous differentials for special service were included these increases would be still greater.

The labor organizations have contended that the employees should receive increases proportionate to the increase in the cost of living, even though the hours of work were reduced. This rule has not been applied to the compensation of other classes and cannot be put in force generally until the effects of the world war are overcome and productivity of labor is increased. The unions have demanded preferred treatment and have received it. There is no basis for the claim that justice has not been done. There are always malcontents in any organization, but the majority of the shopmen are satisfied with the new award, and if the labor organizations try to stir up discontent the roads should combat it by giving publicity to the facts of the case.

It may be recalled that in July the *Railway Mechanical Engineer* commented editorially on the modernization of stationary power plants and referred inadvertently to an article dealing with the installation of superheaters as a means for increasing the efficiency and capacity of the small boiler plant. The article referred to, as written by the assistant engineer of an eastern railroad, appears in this issue and is well worth the attention of mechanical men who are struggling with the problem of getting sufficient power out of the small, antiquated and overloaded power plants that may be found on almost any railroad. If it were practical to add immediately to the stationary boiler plant wherever new boilers are required, the problem would be a simple one indeed. But mechanical men are confronted with the problem of getting results with the means at hand. A change in the grade of coal furnished to the power plant will sometimes work a great improvement and where two or three grades of coal are being received on the railroad it may be possible to select a character of fuel that is more suitable than that in use. Where this can be done, the co-operation of the transportation department should be solicited with a view to having this switched to the overloaded power plant, and if necessary, cars containing this particular grade of coal should be tagged for power plant use, at the junction point where received or in the freight yard where classified.

The *Railway Mechanical Engineer* hopes to publish in an early issue a description of means undertaken on a southern railway to relieve an overloaded boiler plant, where oil fuel was substituted for coal with the result that it was possible to generate sufficient steam without additional boiler equipment. While the installation of superheaters in the stationary power plant as described in this issue involves a greater initial expense than either of the expedients above referred to, the fact that it improves the efficiency as well as the capacity of the power plant should not be overlooked. In this instance the superheaters provided additional power for much less than the cost of the equivalent in new boilers. Where additional boilers would have increased coal consumption the superheaters have reduced it.

One of the most gratifying items in the report of the special committee of the Association of Railway Executives recommending the distribution of about \$184,000,000 of the \$300,000,000 loan fund created by the Transportation Act, is the proposal of loans totaling \$7,062,053 to apply on addition and betterment to 12,616 cars and locomotives. This equipment, now unsuitable for economical service, can be made available for effective use for a smaller expenditure of money, labor and material than an equivalent amount of new equipment can be provided, in a much shorter time.

Of these 12,616 units, 10,675 are box cars. But this number is far short of the possibilities for rehabilitating old box cars. There are probably more than 100,000 box cars of all-wood construction still in service the greater proportion of which are fit subjects for reinforcement. These cars, with wood draft sills, inadequate draft gears and many of them with weak trucks, do not provide adequate protection to the commodities which they themselves carry and are a constant menace to the safety of train operation. They are the cause of frequent delay to train movement and their maintenance requires an amount of labor and material entirely disproportionate to the actual service they render.

Most of these cars would have been retired during the past five years had pre-war conditions been uninterrupted. But to retire more than a small percentage of them now

The Small Power Plant

No Cause for Complaint

Rehabilitate the Wooden Box Cars

\$184,000,000 of the \$300,000,000 loan fund created by the Transportation Act, is the proposal of loans totaling \$7,062,053 to apply on addition

would cripple the resources of the railroads for the handling of grain and general merchandise. On the other hand, to continue them in service in their present condition is exceedingly wasteful. The only logical course is to rebuild and reinforce them. This can probably be done for about one-third the cost of an equivalent amount of new equipment and they will cease to be a factor in the maintenance problem for the next four or five years. An added life averaging 10 years would justify the required expenditure and the saving in maintenance during the three or four years it will be necessary to defer retirement whether they are reinforced or not, adds materially to the attractiveness of the proposition.

The material required for the betterment of these cars can be supplied to take care of more of this work than is now under way. The car departments of every road having even a small number of these cars should consider carefully the possibilities of their rehabilitation and get approval of a plan for carrying out the work. With a program once adopted, it should be carried out as fast as the cars can be put through the shops.

English locomotives cannot be considered impressive from the standpoint of size, weight or tractive power in comparison with American locomotives, nor does there appear to be anything strikingly novel in their construction in view of the fact that British practice is certainly more conventional than our own.

**An Object
Lesson From
Abroad**

However, the impression one receives from the study of a new English locomotive is that the design is the result of the most thorough study and painstaking attention to detail. There is nothing hit-or-miss about the English locomotives. They are usually designed for a specialized service and meet the requirements of that service to a nicety. The best evidence of this may be found in the initial trial trips that are usually undertaken upon the completion of a new English locomotive. The fact that such tests are not customary in this country by no means proves that locomotive development is not on a very high plane here. American manufacturers have done an immense amount of research work, the results of which are at the disposal of the railroads, and American railroads as a whole have had the good judgment to follow the lead of the relatively few roads that have been in a position to do pioneer work on locomotive development. It is doubtful if the spirit of co-operation with respect to mechanical development manifested between railroads in this country is equally characteristic of other countries. However, in this country it is generally taken for granted that a new locomotive is developing the maximum tractive effort specified, that the valves are set just right and that the reverse gear does not creep, that passages between the dome and steam chest are ample and that the locomotive can develop a high degree of superheat. In other words, the locomotive is assumed to be one hundred per cent perfect for the service for which it is designed until reports from various sources, some of which are decidedly non-technical, either tend to confirm or to contradict this assumption. If the locomotive "makes good," that is usually sufficient, although this may be due to the fact that the locomotive has an unsuspected margin of capacity and does not necessarily prove that every part is functioning properly and that its performance could not be further improved by an adjustment or correction in design. The case of the locomotive that does not fulfill the requirements is different. These engines are generally tested but not always as rigidly as they should be, although sometimes the fault is located by a careful test in which the builder usually co-operates. The time will come when specifications on which locomotives are purchased will stipulate that capacity and efficiency be demonstrated under test conditions.

COMMUNICATIONS

STEAM GATHERING PIPE AS A SUBSTITUTE FOR STEAM DOME

DALLAS, TEX.

TO THE EDITOR:

The comments in your editorial (page 256 of the May, 1920, issue) suggest the use of a steam gathering pipe perforated on its top side and extending along the barrel for some distance. The area of the perforations should be in excess of the area through the throttle valve when fully open. This device permits the steam from a much larger volume of steam space than is possible with any steam dome. The liability of water entraining with the steam is thus reduced very considerably. The engines built in the last few years on the Great Western Railway of England have no domes at all, but use a perforated pipe, and engineers have told me that they can carry water from three to four inches higher on these engines than with boilers fitted with domes. I have also seen perforated pipes used in stationary boilers in New Zealand to prevent water being carried over to the engines and the results were quite satisfactory.

P. D. ANDERSON.

SHALL CRAFT UNIONS REPRESENT THE FOREMEN

NEW YORK.

TO THE EDITOR:

Early in June there was issued from the headquarters of the Federated Shop Crafts a circular regarding certain petitions for wage increases which had been presented to the Labor Board and stating that these included adjustments and improved working conditions for foremen. This circular directed that a campaign be instituted to bring all supervisors below the rank of general foreman into the craft organizations, "using every legal means toward that end." The desire for power is inherent in human nature; and as the original field of activities for craft unions had been well covered, an attempt to enlarge this field if possible was natural. The next step would be to control supervision.

The shop foreman, as a rule, has risen from the ranks of labor, has often been a union man, or friendly to organized labor. Previous to government control he too often was denied working conditions and compensation in proportion to his duties and responsibilities, his subordinates often receiving more than he did. These conditions inevitably led to the conviction in the minds of foremen that in organization lay the only means by which they could obtain a square deal and resulted in many foremen joining the craft unions.

In different sections of the country, however, supervisors were brooding over their condition, with the result that they came to the conclusion that their only salvation lay in a supervisors' organization. This gave rise to two organizations, both working toward the same end but with conflicting opinions on some points, rendering it impossible heretofore to unite the two bodies. Consequently foremen are divided into four groups, those belonging to no organization, those allied with the craft unions and the members of the two competitive bodies.

The crafts are antagonistic to the idea of a supervisors' organization for obvious reasons and a definite campaign to suppress this movement and coerce foremen into membership of the craft unions did not come unexpectedly. The question now arising is, what should be the foreman's attitude toward membership in the craft unions? The writer, a shop foreman, offers the following opinions with reasons annexed as the feeling of himself and his immediate associates:

Three elements are necessary for the effective conduct and promotion of business—capital, labor and management. Capital supplies the money to run the business, labor does the work, while the function of management is the employment of capital and the direction of labor in conducting the business. Management is the keystone in the arch of business.

The duties of the foreman are distinctly those of management. He employs, disciplines and dismisses labor directly or by recommendation. He plans and directs the operations entrusted to him. He uses capital when ordering supplies and signing time slips, virtually signing his name to a check on the treasury. He is responsible for the maintenance of the tools and property under his care and carries out the agreements with labor as to wages and working conditions. He also recommends improvements and change in policies, and guards the wellbeing of the employees under his charge.

The duties of the foreman of a half a dozen sweepers are the same on a small scale as those of the general manager; the same principles governing both. The fact that a mechanic may be as able and intelligent as his foreman does not enter into the question. Their duties, conditions of employment, and viewpoints are different and must always be so.

A letter from the Director General shortly before the return of the railroads to private control expressly stated that foremen were officers. Detailed instructions on this basis were issued as to foremen's working conditions.

The functions of a railroad are different from those of ordinary business in that the public grants special privileges, such as the right of condemnation of private property, in order that the railroad may be properly constructed and equipped for operation. These privileges are granted with the understanding that transportation so vital to the public will be maintained, making the railroad a public utility and placing its management a direct obligation to the public.

The man who accepts the position, salary and perquisites of a foreman also shares the responsibilities of the management, one of which is to maintain transportation at all times and under all conditions. While this may be true of the workman as well as of the foreman the workman is not responsible for the operation of the railroad and the foreman should not obligate himself to be guided by the wishes of any body of men who for any reason may undertake to interrupt transportation.

If the power of organized labor could be so extended as to include everyone up to the general manager and a strike of all ordered, one could scarcely imagine what the result would be. Yet this is the principle involved when the union undertakes to control the "bosses."

We hear a great deal now about industrial democracy, which means giving labor a voice in the management. It is possible that at some future time this principle can be applied to railroads, but it will not relieve the management of its responsibility when, if ever, this time comes. Any attempt by a craft organization to legislate for foremen without their authority is unwarranted.

The question now arises as to how the foreman can protect himself from injury resulting from his refusal to be dominated by organized labor, and also to maintain good working conditions, just compensation and the security of his position. As organization is beneficial to capital, and as labor is endlessly proclaiming this privilege, it is but logical that management avail itself of this right. The problems of the yardmaster, roadmaster, station agent, and all those having immediate direction of labor are similar and could be handled by one association, but whether this plan is adopted or these occupations have separate organizations federated, they should be of, by, and for supervision that their problems may be handled befitting their station.

At this time, when all railroad management is working under depressing conditions, the assurance that, no matter what has happened heretofore, no supervising officer will

ever again be compelled to work for less compensation than his subordinates, that his position shall be respected, and his working conditions maintained in keeping with that position, will do much to influence him to stay with the railroads, do his best and refuse to be dominated by organized labor.

HAROLD C. PRENTICE.

EDITORIAL ON WELDING BRINGS REPLY

NEW YORK.

TO THE EDITOR

The editorial in the July issue of the *Railway Mechanical Engineer* entitled, "The Status of Autogenous Welding," points out that the railroads accepted this process as a cure-all during the early developments of the art and states there is grave danger of the re-action now going too far the other way. It is very necessary to have the work properly laid out and prepared; moreover, much depends on the skill of the operator; more than most of us realize. A careful check must be made of the welds each operator is making and the best way is to have in the supervisory forces of the road a man who devotes all his time to looking after welding. On small roads where there is hardly enough welding work done to warrant one man devoting all his time to welding work, a systematic check of welds can be made without much inconvenience on the part of the foreman in charge, by having the operators make test specimens at frequent intervals. The simple process of breaking these specimens will show if the operator is making a good weld; that is, if the metal is thoroughly united. If proper facilities are available, pulling the test specimens on a tensile machine is a much better check. A record should be kept of each check made of the operator's work and while the fact that test specimens show up well does not guarantee that other welding work will be as strong, it will go a long way towards insuring good welds.

Some roads that have gone into firebox repairs by autogenous welding have been enabled to lengthen out firebox life as much as 100 per cent. Side sheet renewals are being made on boilers of types that absolutely prohibit the riveting process. Patches are being successfully welded in back flue sheets at practically all locations in the sheet. The money saving involved is so much that it will pay any road to have its supervisory forces spend sufficient time to check the operator's work. Almost any method would really be warranted that would keep the autogenous process of doing boiler work in use in preference to going back to the old methods.

One of the things that has had a lot to do with the present re-action on this subject is the over-enthusiasm that was displayed on the welding of small boiler tubes to back flue sheets. Occasional leakage of tubes is eliminated by welding but a number of roads have welded tubes in engines, particularly where water conditions are not good, with disastrous results. In bad water districts, or in localities where there is quite a scale formation on the tubes and flues immediately adjacent to the tube sheet, much trouble has been experienced with welding small tubes. The tube either develops longitudinal cracks after a few months' service or the bridges in the tube sheet crack.

That scale formation causes these troubles has not been proven conclusively, although scale deposit has a tendency to prevent the water from properly cooling the sheet. The theory is that using the prosser expander reworking unwelded flues loosens this scale so that it may be washed out.

If a locomotive will give reasonable mileage with small tubes unwelded, there is no particular point in welding them as there is grave danger of bringing about attending troubles that are much worse than occasional tube leakage. The art of electric welding is still in its infancy in spite of the fact that there have been wonderful developments made during the last few years. It certainly would be unfortunate if the re-action was to result in the railroads neglecting the art.

North Eastern Mineral Hauling Locomotive

NORTH EASTERN BUILDS MINERAL LOCOMOTIVES

These Engines Typify English Designs and with a Tractive Effort of 37,000 lb. are Relatively Powerful

BY ROBERT E. THAYER
European Editor of the *Railway Mechanical Engineer*

THE North Eastern railway has recently built and placed in service some of the most powerful freight engines used in Great Britain. These engines were built in the company's shops at Darlington, to the designs of Sir Vincent Raven, the chief mechanical engineer of that road. They are classified as mineral locomotives of the T.3 type having an 0-8-0 wheel arrangement. These engines are to be used in the coal traffic in the Newcastle district and are designed to haul a load of 1,400 metric tons (1,543 short tons) on a 0.5 per cent grade. They have three simple cylinders 18½ in. by 26 in. They weigh 160,380 lb. in working order, the total weight of the engine and tender being 259,200 lb. They have 55¼ in. drivers, carry a boiler pressure of 180 lb. and have a rated tractive effort of 36,960 lb.

These engines are considered powerful for English practice. They are built very nearly to the clearance limitations of the North Eastern. The width over cylinders is 8 ft. 9 in. which is 3 in. less than the minimum clearance width

consisting of a dynamometer car, 60 loaded coal cars and a brake van or caboose having a total load of 1,402 long tons. This train was tested over a 60 mile section having a ruling grade for a short distance of 0.57 per cent. The contour of the line is such that there is a steady pull to the summit of the grade. The maximum drawbar horsepower developed in these tests exceeded 1,100 d.h.p. On the test trip running in the opposite direction there is a ruling grade of 0.93 per cent for about 4 miles. The train in this direction consisted of the dynamometer car, 60 loaded freight cars and a guard's van which gave 787 long tons as the total weight of the train. During this test the train was stopped on the ruling grade and a start was made with a drawbar-pull of 28,000 lb. and the speed was increased to 16 m. p. h. in seven minutes after starting.

These locomotives are equipped with the Schmidt superheater, brick arches, steam reverse gear, force-feed lubricators to the cylinders, the Lockyer double-beat throttle valve and exhaust steam injectors.

Following is given a brief description of these locomotives together with a description of some of the practices followed in their construction.

Fig. 2—Plate Frame for North Eastern Mineral Locomotives In Process of Construction

Fig. 3—Horn Facing Machine for Finishing Pedestal Jaws

and the top of the stack is 13 ft. 1 in. above the rail which is 5 in. less than the minimum height clearance. The general arrangement drawing is shown in Fig 1 (page 506).

These engines were given a dynamometer test with a train

Construction Details

These engines following the customary British practice are equipped with plate frames which are 1⅛ in. thick, 3 ft. 7½ in. deep between pedestals and 2 ft. 1½ in. deep over the pedestals, being spaced 4 ft. apart. These frames are shown in the process of erection in Fig. 2. No system of

Fig. 1—General Arrangement of the North Eastern Mineral Locomotives

equalization is provided on these locomotives and the heaviest axle load is carried on the first pair of drivers which amounts to about 41,000 lb. No shoes or wedges are used on these engines as a careful machine fit is made between the driving box and the pedestals. The pedestal jaws are faced with a special device known as the horn facing machine, a picture of which is shown in Fig. 3. This is a portable device and its method of application is indicated in Fig. 4 which shows a repair engine having its pedestals refaced. With this machine an accurate surface in the pedestal jaws is obtained, the degree of accuracy being indicated by a clearance limitation of .008 in. between the driving box and the pedestal faces of the leading drivers and a clearance of 0.13 in. between the driving box and the pedestal for the axle under the firebox. An additional clearance is given to this driving box on account of its proximity to the firebox where an allowance must be made for expansion of the parts.

The driving boxes are lubricated from oil cups attached to the frames. Two lubricating pipes pass from each cup to each of the leading boxes and five to the rear driving boxes. Additional lubrication is required in this case on account of the heat to which the driving box is subjected from its proximity to the firebox. Force-feed lubrication is provided for the valves and cylinders, the force-feed lubricator being placed just above the leading axle on the frames and deriving its motion from a system of levers coupled to the inside valve rod. One interesting feature in the construction of this engine, in fact all engines built in these shops, is the fact that the cylinders, which in this particular case are all in one casting, are mounted on a dummy frame and the cross heads and other motion work are placed in proper alinement. A view of this dummy frame is shown in Fig. 5. It will be seen that there is plenty of space to get at the various parts which greatly facilitates the work.

This fitting having been carefully done these parts can be mounted directly onto the frame of the locomotive without additional adjustment. In a like manner the valve motion links are adjusted on the link truing table preparatory to their being applied to the locomotive and thus effecting a considerable saving in time.

This locomotive having three cylinders requires the cranked axle which in this particular case is of the solid type, although the built-up type is used to some extent on this road. The rods drive on the second axle and Fig. 6 shows this axle with the wheels mounted and after the eccentrics and the driving boxes applied. The cylinders which are shown in Fig. 7 are cast in one piece. They are bored on a special machine (Fig. 8) which was designed especially for three cylinder work and which permits all three cylinders, and by special attachments, the valves also, to be bored at one time. The valves used in these engines are shown in Fig. 9.

Boiler

No less care is taken in the construction of the boiler than in the construction of the rest of the locomotive. A drawing of the boiler is shown in Fig. 11. It is made up of three

Fig. 5—Rear View of Dummy Frame

parallel rings of 66 in. outside diameter. The barrel plates are $\frac{5}{8}$ in. thick, the front tube sheet $\frac{7}{8}$ in. thick, the wrapper sheet $\frac{5}{8}$ in. thick and a back head of $\frac{5}{8}$ in. The firebox is made of copper, the roof and side sheets being made of one piece and being $\frac{5}{8}$ in. thick. The tube sheet is 1-3/16 in. thick, being narrowed down to $\frac{5}{8}$ in. thick at the throat

Fig. 6—Cranked Axle Ready for Application to the Locomotive

This boiler has 102, 2-in. tubes and 24, 5 1/4 in. superheater flues and 7 stay-tubes. The distance between tube sheets is 16 ft. 2 5/8 in. Through these stay-tubes pass stay-rods of 1 in.

Fig. 4—Horn Facing Machine Applied to Repair Engine

Fig. 7—Cylinders for North Eastern Three-Cylinder Mineral Locomotives

diameter which are held by cap nuts at the tube sheets. These are shown in the boiler drawing.

Contrary to a very general practice used in England and also on the North Eastern whereby an angle ring is used on the front end of the boiler to which is riveted the barrel

Fig. 8—Machine for Boring Cylinder Castings

and the front tube sheet, as indicated on the left hand of the boiler barrel shown in Fig. 11, the front tube sheet of this boiler is flanged and riveted directly to the boiler barrel. The back head is flanged on its periphery to provide for riveting it to the firebox wrapper sheet from the outside. Likewise a similar joint is made with the copper

practice is common throughout the English railways. After the barrel sheets have been trimmed and rolled they are held by straps of scrap iron bolted into "tack" holes which are drilled in the sheets before they are rolled. All three courses being treated in the same manner the process of assembling is as follows: The middle or dome course is placed end up on the floor. The circumferential welt plate, being bored to a diameter $\frac{1}{8}$ in. less than the outside diameter of the boiler barrel, is heated to a cherry red and placed over the upper end of the dome course and held in position by tack bolts. The third barrel ring is then fitted into place by means of an overhead crane and is also held in place by tack bolts. The welt is thus shrunk on to the barrel sheets. (It should be mentioned, in passing, that the only holes drilled in these sheets and the welt strips are those necessary for holding them together with tack bolts. These holes are of a smaller diameter than the rivets and are redrilled as explained later.) With the second and third courses thus united the same process is carried through in applying the circumferential welt to the first and second courses.

After both rings have been put in place and securely fastened, and the longitudinal welt strips "tacked" in place, the boiler is taken to a boiler barrel drilling machine which is shown in Fig. 11. All rivet holes both for the longitudinal and circumferential seams are then drilled in this machine. This is done to obtain a true radial rivet hole and one that

Fig. 9—Piston Valves for North Eastern Three-Cylinder Locomotives

back sheet of the firebox and the back head at the door. This is not common practice in England, a door ring being the customary form of construction.

It will be noted from the boiler drawing that the barrel courses are butt riveted on the circumferential seam. This

will exactly match in the welt strips and plate thus making any drifting unnecessary. After all the rivet holes have been drilled the longitudinal welt strips are removed and the surfaces of the boiler and welt strip thoroughly cleaned. Every hole is then slightly countersunk with a pneumatic

rotary machine. The butt straps are again replaced and the boiler is ready for riveting in a bull riveter.

The rivet and staybolt holes in the firebox wrapper sheets and copper roof and side sheets are drilled on the flat to slightly less than the ultimate diameter, four or five sheets being drilled at a time with, of course, the top sheet being the only one "laid out." The sheets are then rolled to

between them to represent the water space. These plates are clamped together and the rivet holes through the two sheets drilled. The copper back firebox sheet is then taken to a machine and the door-hole machined out. Copper staybolts are used for the firebox. These are cut off to give a 7/16 in. stay head in the copper sheet and 3/8 in. head in the steel outside sheet. A long stroke pneumatic hammer

Fig. 10—Boiler Drawing for North Eastern Locomotives

shape and after they are assembled, the rivet and staybolt holes are reamed out to the proper size.

All of the copper sheets are flanged by hand with the exception of the door-hole in the back firebox sheet which is done in a press. All the steel flange work is done in the hydraulic presses. After the back firebox sheet and the back head have been flanged and trimmed they are carefully fitted together at the door hole, distance pieces being placed

with a pneumatic holder-on is used in riveting the stay bolts. The foundation ring, which in this case is 3 in. by 4 in., is machined on the outside and on the inside corners. In cases where steel fireboxes are used it is machined on both inside and outside.

While a large number of English roads use the ferrules between the tubes and the tube sheet, it is not the practice on the North Eastern. The tubes extend through the copper

tube sheet $\frac{3}{8}$ in., for beading, and about $\frac{1}{2}$ in. through the front tube sheet. The tubes are rolled by a three roller expander driven by a pneumatic portable machine and are beaded on the firebox end only, with the exception of the stay tubes which are beaded on both ends. The ends of the superheater flues extending through the firebox tube sheet are machined on the outside and care is taken to prevent any scale or foreign matter from working in between the sheet and the flue. These flues are then expanded by a special five roller expander and beaded as in the case of the small tubes.

The North Eastern has a particularly well equipped boiler

Fig. 12—Lockyer Double Beat Valve Showing Assembled Valve and Separate Parts

shop which is of sufficient capacity to more than take care of the needs of the road.

Special Attachments

Among the attachments to this locomotive may be mentioned the "Lockyer" double-beat throttle valve, designed by N. C. Lockyer, the works manager at Darlington. This is shown in Figs. 12 and 13. The purpose of this valve is to obtain a more nearly balanced valve than is possible with the ordinary construction of double seated valve. In order to do this it has been necessary to split the valve body into two parts as indicated in the drawing and illustration. The joint between these two parts is a carefully made steam tight fit. In this particular case the diameter of the upper and lower valve seats are exactly the same, being $6\frac{1}{8}$ in. This, of course, could not be obtained with the valve in one

piece as it would be impossible to place the valve in position. This is overcome in the "Lockyer" valve by passing the lower portion of the valve through the opening at the

Fig. 13—Lockyer Throttle Valve for North Eastern Locomotives

right of the throttle pipe casting and putting the upper part through the top of the casting in the customary way, the two

Fig. 11—Boiler Barrel Drilling Machine

parts fitting snugly to each other. They are bolted in position on a spindle. This construction permits of any combination of valve diameters desired.

It will be noted from the drawing that the upper valve has a conical baffle whereas the lower valve has a straight cylindrical base. This provides a gradual flow of steam into the dry pipe when the throttle is opened. There is an indicator placed on the throttle handle in the back head (Fig. 14) which gives the engineer indication of the throttle opening. The action of the baffles is such that the different positions of the throttle quadrant provide a steam area according to the following table:

Division of quadrant	Total area open to steam, square inches	Division of quadrant	Total area open to steam, square inches
1.....	0.00	7.....	7.74
2.....	0.54	8.....	10.62
3.....	1.08	9.....	13.32
4.....	1.62	10.....	16.38
5.....	2.83	11.....	19.98
6.....	5.22		

These engines are also equipped with a steam reversing mechanism which is indicated in the general arrangement drawing. The steam cylinders for operating the gear are located between the second and third drivers underneath the

Fig. 14—Cab of North Eastern Mineral Locomotive

locomotive. The steam cylinder takes steam from the dome through a valve on the right hand side of the engine which is operated from the horizontal handle shown at the right of the cab in Fig. 14. This handle is attached to a rod, passing through the handrail, which is coupled to the control valve by a system of levers. The piston of the reversing mechanism is connected through a system of levers to an indicator in the cab which is shown indistinctly on the right hand side of the boiler head. The back head arrangement is characteristic of British practice.

General Dimensions

These engines are the latest to be constructed by the North Eastern and bear a great similarity to a 4-6-0 design, which is also new, for fast freight traffic. These engines use the

same cylinder castings and the same boiler. The dimensions of the 0-8-0 type are given below:

Type	0-8-0
Gage	4 ft. 8½ in.
Service	Heavy freight
Fuel	Soft coal
Tractive effort	36,960 lb.
Weight in working order	160,380 lb.
Weight on drivers	160,380 lb.
Weight on engine and tender in working order	259,200 lb.
Wheel base, driving	18 ft. 6 in.
Wheel base, total	18 ft. 6 in.
CYLINDERS	
Kind	Simple
Number	3
Diameter and stroke	18½ in. x 26 in.
VALVES	
Kind	Piston
Number	3
Diameter	8¾ in.
WHEELS	
Diameter over tires	55¼ in.
BOILER	
Style	Straight
Working pressure	180 lb. per sq. in.
Outside diameter	66 in.
Firebox, length and width	9 ft. by 3 ft. 11 in.
Tubes, number and outside diameter	102—2 in.
Flues, number and diameter	24—5¼ in.
Stay tubes, number and diameter	7—2 in.
Tubes and flues, length	16 ft. 2¾ in.
Heating surface, tubes	1,407 sq. ft.
Heating surface, firebox	166 sq. ft.
Heating surface, total	1,573 sq. ft.
Superheater surface	530 sq. ft.
Equivalent heating surface	2,368 sq. ft.
Grate area	27 sq. ft.
TENDER	
Tank	Six wheel
Weight	98,800 lb.
Water capacity	4,125 gallons
Coal capacity	5½ tons

ANTI-RUST COMPOUND

While statistics are not available, the total waste due to the rusting of machinery, tools, ordnance and metals amounts probably to millions of dollars annually. Various rust preventives invented and used from time to time have been more or less efficient in specialized fields. For example, paint is a most effective covering for products exposed to the weather. For bright polished steel surfaces, some form of heavy oil or grease is commonly used.

Experience with these compounds has developed the need for three inherent characteristics. First, they must form a protective covering and not melt easily. Under commercial conditions of storage and shipment, temperatures of 70 deg. F. to 100 deg. F., or higher, are common, and petroleum and other greases and compounds flow and drip off at these temperatures, exposing the bright surfaces to rust when the temperature has lowered and moisture collects on the metal. Second, they must be easily removed. Obviously a length gage, accurate to within .0001 in., cannot be covered with a compound that requires the application of emery cloth to remove it. The third requirement is ease of application.

A rust-preventing compound called Stazon, which is said to fulfill these three requirements, has been developed by the Conversion Products Corporation, New York. It is easily applied and removed by the simple act of wiping, and being an inert compound will not flow at high temperatures. To prove this fact a large number of trade-paper editors recently were invited to witness a demonstration. Four samples of anti-rust compounds, including Stazon, were placed on a metallic plate, the temperature of which was gradually raised by means of an electric resistance coil mounted on the back. The first compound started to melt at approximately 80 deg. F., and at 115 deg. F. three of the compounds had melted and completely run from the plate. Stazon remained and did not begin to soften until the temperature had reached over 200 deg. F., a temperature higher than would be found in any ordinary conditions of storage or shipment. It was stated that this compound when applied to metallic surfaces formed a coating impervious to moisture or atmospheric fumes.

RAILROAD AND INDUSTRIAL SHOP MANAGEMENT

A Frank Discussion of the Situation in Railroad Shops Compared with Industrial Conditions

BY C. C. EDMONDS

THE unsolved problems in the motive power and car departments of a railroad are numerous and knotty, but some of them are quite evident to the shop man or foreman who is in constant contact with the work. My own experience which has covered a number of years and a variety of railroad shops and roundhouses has brought me into contact with some of the simpler problems involved in these departments.

The railroad method of doing things had always seemed about right to me until chance dropped me into the manufacturing of high grade machinery and tools. Although not high in the official realm of the various manufacturers with whom I came in contact, I did have opportunity to see new methods and new systems, and was able to contrast them with what I had seen during my railroad days. Consequently, when I returned to railroad work this contrast was decidedly marked and, I must confess, not exceedingly favorable to the manner in which railroad shops are managed. Realizing as I do that the typical railroad shop is not of the production or repetition type of industry and that the work cannot be centralized as in industrial practice, it still seems to me that on many points the railroads are decidedly weak.

Handicapped by Lack of Equipment and Materials

An illustration of how production is held up on many railroads is furnished by the present conditions in a 23-stall roundhouse in the Middle West. The machinists are all well equipped with hammers and chisels, but other than that their equipment is negative. There were only three pipe wrenches in the entire place, and it was a case of waiting until the other fellow was through with them. The back up belt on the one and only lathe has been off six weeks waiting for the stores department to issue a new one, but so far the prospects are that it will be several more weeks before the belt is forthcoming. An order for an emery wheel brings results within two months, if sufficient pressure is brought to bear. A much delayed order for sheet rubber for gaskets necessitated the use of canvas and varnish to make a gasket for an air compressor.

The idea of withholding supplies from the mechanical department in order to prevent wastage results in enough time being used in making parts to pay for them many times over. Personally, I have often had to make parts of such common accessories as gage cocks and boiler checks, not to mention robbing other engines of such parts as had not previously been appropriated.

The lack of shop equipment is particularly noticeable after one has been fortunate enough to work for a progressive industrial concern. Electric lights are a rare novelty in a majority of the round houses in the United States, and a new installation warrants a full page or two in the company magazine. It was once my ill-luck to desire electric lights for a shop of which I was night foreman. Consequently, I found a junk dealer who was willing to give me a generator, wire, etc., for a corresponding amount of old iron. By dint of much hard labor and "raids" on various other departments, the system was finally installed and extended so that it included the office, storehouse, engine despatcher's house and the machine shop. We were most jubilant about our improvement, and everything went serenely until the superintendent of motive power made a little inspection trip and, noticing our system, inquired as to our authority for the same.

As we had none, his highness ordered the removal of our pet, so that the place has since been and is still illumined by lanterns and oil lights.

Previous to this occurrence we had been fortunate enough to make a trade with our junk man friend for an old air compressor, so that when it had been rebuilt we were well fixed for air pressure. This unauthorized move likewise caused considerable correspondence and orders concerning further procedure, but as the old air pump had been dismantled and sent to the shops there was no option about keeping the new addition, which is still running satisfactorily. However, if ever again I feel in the mood for making improvements in shop equipment they will first be sanctioned by higher authority and the material will be furnished on order. Initiative may be a virtue, but it is apt to get one into trouble in a railroad shop.

No Encouragement for the Foreman

Some time ago in the *Railway Mechanical Engineer* the life of a roundhouse foreman was aptly described by the author who said that if one wanted to find the foreman he needed merely to look around and if there was an engine with a dome cap off then undoubtedly the foreman's legs might be seen waving in the air therefrom. If the foreman could devote his entire time to the condition of his power this description would not be so absurd, but when we find the same man the next minute sweating over an elaborate report we can better appreciate his predicament.

Besides the task of planning shop work for the men, the foreman is inspector, disciplinarian, shop despatcher, turntable expert, call boy, employment manager, machinist, bookkeeper and office manager. The majority of foremen until recently have been absolutely overloaded with clerical details which are foreign to their training or inclination. In theory the roundhouse clerk was hired to keep the time books and attend to reports, but in practice the foreman usually had to recheck the entire outfit. A reduction of the variety of the foreman's duties would be a much needed step toward improvement. No foreman in a progressive industrial plant is harassed with so confusing a variety of responsibilities. He has the time and is generally permitted to plan his work deliberately, with the result that far more is in reality accomplished.

Many large industrial plants find that foremen's meetings held occasionally are of great value, and while the element of distance might interfere it would seem that quarterly meetings would be a big help to the foreman in giving him opportunity to acquire new ideas and to learn of new methods. The foreman could well be supplied with the current number of a good trade journal applicable to his particular work, so that he can keep ahead of the times.

In order to secure better and increased production, loyalty to the road must be secured. This can be gained only where both parties to the contract are fair and square. Men working in a shop, however large or small, notice the attitude of the management toward the foremen, and if it is a fair one the men respond favorably. Otherwise they figure, "Well, the company doesn't seem to care about its executives, and so why should I strive for promotion?" Wherever one goes and talks to railroad men he either discovers that "This company is all right and will take care of me," or "This company is n. g. and isn't interested in me." In the first instance he

will find that the men are loyal and will do the right thing by the company, while in the second case he will observe that it is a case of getting by as easily as possible and an "I-should-worry" attitude toward their work.

Push vs. Pull

Promotion on merit is greatly inducive to loyalty. If a man can be assured that he will be either promoted on his merits or fail if he does not qualify, he will work to the best of his ability. Otherwise, the better men will leave for other work because of lack of opportunities in railroading. I have had the privilege of talking to at least a dozen of the bigger railroad mechanical men throughout this country, and in every case when asked, "Would you want to go into it again?" they have said, "No, it's too hard a game and absolutely thankless." Such an attitude by the "big" men does not speak well for the attitude one must of necessity find in the ranks. For this reason railroading today cannot be said to be a very attractive profession or job for a well-trained young man as compared with opportunities in the industrial field.

Besides securing the right attitude of the men toward better production by securing more loyalty through right treatment of executives and fair promotion, much could be gained by the elimination of the present practice of "meeting the dividend period." In the case of most roads a big reduction in the number of mechanical employees is usually made about two months before the end of the fiscal year so that the net income can be boosted a bit thereby. In more than one roundhouse I have seen an entire emergency crew of machinists and boilermakers, plus a goodly quota of master mechanics and roundhouse foremen, trying to give the regular force a lift over a hard cold spell. Invariably one can find on inquiring of the foreman that engines were slipped by during the summer simply because of the approaching dividend period.

A Business Organization Needed

The presence of a good, well-balanced organization means that friction between departments and men is reduced to a minimum, while a loose organization means every department or man for itself or himself. An instance with which I am familiar will illustrate the average type of organization which one finds in the railroads today. At a division point into which three divisions ran from various directions (the division offices being at the other end of the line), the roundhouse foreman received a wire ordering him to get a certain extra engine there ready to go out light over division No. 1. Shortly afterward division superintendent No. 3 was wiring for the engine, and then the home division, or No. 2, also claimed the engine. (It was just out of the shop.) No one seemed to know whose engine it was, so the roundhouse foreman put it switching and sent the telegrams to the superintendent motive power for him to straighten out the mess. Instances like the above are happening every day on the various railroads, and the result is no one knows who actually is boss.

It would seem that as other large companies, especially manufacturers, have proved that organization does pay, the railroads could well afford to get a definite understanding of the problem and then put the solution down in the form of an organization chart so that every man could have some idea of what his authority covered and to whom he was responsible. The constant "passing the buck" from one department to another could be stopped by higher officials requiring that their men assume responsibility and take the burdens together with the benefits. At present too many executives are simply a screen through which complaints, etc., are sifted until the little fellow (the fine mesh screen) has to catch it all and take his officers' burden. A demand that officers assume their own liability and no other should be strongly enforced, and the presence of an organization chart, together with some few standard written instructions as to general practice, should be of benefit. The present financial situation of the railroads

is such as to make unlikely any betterment in tools and equipment, but nevertheless a goodly saving could be accomplished if the organization tangles could be straightened out and permanently recorded. The main expense involved would be the use of good, ordinary common sense and an efficiency expert would not be necessary, as the railroad men have plenty of brains and ability if only they could be given a chance to use them.

NEW PIECE WORK SYSTEM IN GERMAN SHOPS

A new system of piece work, which is of the nature of profit sharing, has been introduced in the government's railway repair shops at Golm-Mark and has led to increased production. A commission composed of a works manager, a delegate of the workers and a railway official calculates the number of hours necessary for the performance of a certain piece of work, on the basis of actual experience and average production. By a special scheme the saving in cost resulting from the difference between the actual number of hours worked and the calculated number is shared between workers and employers. Each individual worker is paid according to output and capacity on a scale arranged between the management and the workers. The resulting average of hours and wage rates is that for which payment is agreed upon in the repair contract. If, for instance, the agreed average price per hour is 2.30 marks plus 180 per cent for general expenses (some such percentage is usually allowed to every firm of contractors as compensation for expenses) the following result will obtain.

A railway freight car, according to the standard calculated, requires 500 hours for repair. The work is actually performed in 408 hours, so that a saving of 92 hours is effected. Ninety-two, the number of hours saved, multiplied by 2.30 marks gives 211.60 marks. The 180 per cent for expenses amounts to 380.88 marks; the sum of the two is 592.48 marks. Half of this sum, or 296.24 marks, goes to the gang of 10 workers employed on the job. The combined wages of these 10 workers for the job in question were 947.90 marks. The extra compensation of 296.24 marks paid to them for the saving in time amounts, therefore, to somewhat over 31 per cent.

Newly employed workers are paid a share of the profits after 12 days' work with their gang. The standard number of hours fixed by the commission is not reduced when the worker receives higher wages.

According to Vorwaerts (Berlin) this system has already been in use in the workshops for four months. As a result production has increased 100 per cent. Another advantage is that the employment of supervisors has become unnecessary. Further, if any member of a gang shows a lazy disposition the other members refuse to incur the loss of profit involved and demand his dismissal.

HARDENING GAGES WITH MINIMUM DISTORTION.—One of the laws governing the hardening of steel which has recently been discovered is that quenching while crossing an arresting or recalescence point produces the least amount of distortion. This is borne out by experiments conducted at Goldsmith's College, London, described in a paper before the Institution of Mechanical Engineers. In endeavoring to produce screw gages of extreme accuracy the effect of variations in the quenching temperature on a large number of gages was checked. While no temperature was found at which the steel was not distorted, the experiments showed that parts quenched at 700 deg. C. (1,292 deg. F.) increased in length by .0002 in. in .7 in. of length, which is within a pitch tolerance of .0003 in. per in. of length. Such slight errors are not serious as they can be removed by a grinding or lapping, which is usually necessary to give the required finish.

HOW FRONT END AIR LEAKS CAN BE PREVENTED

Some of the Bad Effects of Front End Air Leaks and Means for Their Correction

IT IS questionable if the serious effects of front end air leaks are fully appreciated and whether adequate measures are being taken to prevent their bad effects. The direct result of air openings in the front end is to reduce the vacuum in the smokebox and lessen the draft on the fire. This in turn necessitates the use of a smaller nozzle area to produce the desired draft. A reduced nozzle increases the back pressure in the cylinders, from which it is apparent that the efficiency of the locomotive is directly affected by air leaks in the smokebox.

It has been pointed out that these air leaks do not usually develop suddenly and that their effect on the draft is gradual. Consequently as the steaming qualities of the locomotive are gradually impaired the nozzle is invariably bushed down or a bridge is required. If these front end air leaks oc-

Fig. 1—Usual Type of Joint Between Smokebox and Outside Steam Pipe

curred suddenly their effect would be so noticeable that they would unquestionably be investigated and corrected.

The harmful effect of a front end air leak often remains after the leak itself has been stopped up, for after a nozzle has been bushed down or bridged to counteract the effect of an air leak in the front end, it is not always enlarged to its former dimensions as soon as the air leak has been closed. In fact, it is quite common for locomotives that have required a reduction in nozzle size for some cause or other, to keep on running with the reduced nozzle long after the immediate cause has been removed. Only the strictest supervision over this matter will result in the elimination of needlessly restricted nozzles.

Principal Cause of Front End Air Leaks

Outside steam pipes are not the only cause for front end air leaks but they can doubtless be regarded as the principal cause. The most troublesome point in connection with this construction has been to close the aperture in the smokebox shell through which the steam pipes pass to the cylinders. Obviously these pipes cannot be rigidly connected to the boiler shell at this point and must be allowed freedom of movement to allow for contraction and expansion. Outside steam pipes possessed so many advantages and adapted themselves so readily to superheater installations

that the difficulty of maintaining a tight joint between the smokebox and the steam pipes was somewhat overlooked and the earliest joints intended to prevent air leaks have proved more or less inadequate from this standpoint.

Fig. 1 shows an arrangement that has been applied to a large number of locomotives. The gland is packed, preferably with asbestos rope, and if this packing is carefully maintained the joint will remain tight. However, it must be observed that the pressure on this packing, resulting from a vacuum in the front end, tends to loosen rather than compress the packing, and it will usually work loose so as to admit air, unless frequently attended to between shoppings. The use of any cement in this gland as a substitute or makeshift to reduce the time and expense of frequent repacking is not a desirable expedient. The cement soon develops cracks through which air is admitted to the smokebox, and often crumbles and drops out of the gland altogether. This is due to the fact that the cement contains moisture at the time the joint is packed which invariably dries out causing the packing to shrink around the steam pipes. The use of cement for this purpose cannot be too strongly condemned.

What Tests Developed

A simple torch test is all that is required to determine the presence of air leaks and it is earnestly recommended that this test be made *periodically* on *all* engines. At a sin-

Fig. 2—Improved Type of Joint for Outside Steam Pipe

gle engine terminal recently where this test was applied at random to 29 engines, all but one were found to have air leaks around the steam pipe. On this railroad cement had replaced the asbestos packing and it was not the practice to test for air leaks unless the locomotive was reported for failure to steam. Similar tests conducted at terminals where the use of cement had not been resorted to developed a better state of affairs, but irrespective of the method of packing and even the type of construction, the entire elimination of front end air leaks can only be secured through the most vigilant inspection.

A test was conducted by the Fuel Conservation Section of the Railroad Administration for the purpose of determining the exact effect of reducing nozzles and disarranging

front end apparatus to overcome the effects of front end air leaks. In this test no particular locomotive was selected, the locomotive tested being one in regular chain gang freight service and assumed by all concerned to be in good condition. The first trip was made with the locomotive as found. On completion of the trip the openings around the steam pipes were packed with rope asbestos and it was found that this resulted in raising the average draft sufficiently to warrant an increase in the size of the nozzle. On the succeeding trip the openings around the steam pipes were again packed with asbestos and cement as a greater part of the packing had pulled out on the previous trip and a further enlargement of the nozzle was made. The results of successive test trips showed that with proper redrafting of the locomotive and stoppage of all air leaks, an increase of 9.3 per cent in the area of the exhaust nozzle was possible.

Improved Construction to Prevent Leaks

The use of a packing gland with means for maintaining the packing in place as shown in Fig. 2 is one of the most practical and certainly the most substantial means for obtaining a joint which, if properly packed, will remain tight from shopping to shopping. This form of construction was applied to quite a large number of locomotives, including

Fig. 3—Air Tight Joint Developed on Southern Pacific Lines

all of the locomotives built for the Railroad Administration. The application of this or an equivalent device to existing locomotives, as well as to all new power cannot be too strongly urged. The use of cement, as has been pointed out, is altogether unsatisfactory and the application of other material without means for holding it in place will necessitate frequent inspection and repacking.

Another form of construction designed to make the joint around the steam pipe air-tight which was first developed on the El Paso division of the Southern Pacific lines is shown in Fig. 3. The casing applied to the outside steam pipes is made of $\frac{1}{4}$ -in. steel plate with a welded seam. This casing is riveted permanently to the smokebox and then caulked or welded around the edge to make it air-tight. It is large enough in diameter to permit the removal of the steam pipes and a wrought iron ring is attached to the lower end as shown. A cast iron flange made in halves is fitted together and bolted snugly around the steam pipe, which is machined true at this point. The cast iron flange is secured to the wrought iron ring by means of studs and a copper wire gasket inserted to obtain an air-tight joint. A copper gasket is then caulked into a dovetailed groove in the cast iron flange surrounding the steam pipe.

Other Means for Correcting Leaks

Front end air leaks around the steam pipes may be corrected on a large number of locomotives on which this has been a source of trouble, by redesigning or inserting an effective packing gland to protect this joint. Fig. 4 illustrates a device that was designed to prevent air leaks around the outside steam pipes, but has never proved very satisfactory from this standpoint. On locomotives so equipped it would be better to discard all of this casing, except the flanged piece attached to the smokebox, and substitute a

Fig. 4—Early Design to Prevent Air Leaks

stuffing box and packing gland as shown in Fig. 5, which, can be easily accomplished with the addition of two castings.

The problem of avoiding leaks at outside steam pipes is one that requires not only persistent attention in the engine terminal and shop, but should be carefully considered by mechanical engineers in designing new locomotives and improving old locomotives as they go through the shops. It is safe to say that wherever outside steam pipes are in use, a large percentage of locomotives will be found to have air

Fig. 5—Application of Stuffing Box and Gland to Design Shown in Fig. 4

leaks around the steam pipes, unless special precautions are taken in design as described in the foregoing, or unusual care is exercised with respect to this detail of locomotive maintenance. It is entirely possible that the design of an air-tight joint can be further improved, but it is of greater importance that the application of some of the improved designs already available be made more universal.

Individually, the front end air leak is never too small a matter to be overlooked and in the aggregate the loss in locomotive efficiency and capacity occasioned by front end air leaks will approach a surprising total on almost any railroad.

RAILROAD LABOR BOARD DECISION ANNOUNCED

Total Award \$600,000,000; Flat Increase of Thirteen Cents an Hour for Foremen, Mechanics and Helpers

THE United States Railroad Labor Board on July 20 announced its decision in the demands of the labor organizations for increased wages and changes in working conditions. The board reserved decision on the questions regarding working conditions and awarded flat hourly increases over the rates established by the Railroad Administration. The average increase is approximately 21 per cent of the present rates of pay and will add about \$600,000,000 to the annual pay roll.

In separating the question of wages from related subjects such as the continuation or elimination of the National Shop Agreement and the application of the award to the various outlaw organizations, the board stated that adequate investigation and consideration of these questions would demand much time and because of the existing tense labor situation it was desirable to make as early a decision of the wage question as practicable.

The actual additions to the total payroll of the larger classes of employees (allowing nothing for overtime) are estimated as follows:

		Approximate percentage increase
Yardmasters and train dispatchers.....	\$4,767,357	
Clerks	103,920,176	25
Maintenance of way employees.....	160,297,568	25
Mechanics and shop laborers.....	139,237,215	19½
Agents and telegraphers.....	21,281,669	23
Enginemen	65,025,012	23
Trainmen	91,561,335	
Marine employees	250,000	
Total	\$586,340,336	

The introduction to the board's decision reads in part as follows:

In arriving at its decision, the Board has taken into consideration, as the Transportation Act prescribes:

- "(1) The scale of wages paid for similar kinds of work in other industries;
- "(2) The relation between wages and the cost of living;
- "(3) The hazards of the employment;
- "(4) The training and skill required;
- "(5) The degree of responsibility;
- "(6) The character and regularity of the employment, and
- "(7) Inequalities of increase in wages or of treatment, the result of previous wages or adjustments."

The Board has been unable to find any formula which applied to the facts would work out a just and reasonable wage for the many thousands of positions involved in this dispute. The determination of such wages is necessarily a matter of estimate and judgment in view of all the conditions; a matter on which individuals will differ widely as their information or lack of it, their interest, situation and bias may influence them.

With reference to "the character and regularity of the employment," the Board finds that with few exceptions railroad employment is more regular, and the character of the work is more desirable than like occupations outside. As a rule railroad employees are such for life and usually remain for years with the same company. This permanence of employment has certain advantages which have been considered by the Board. With regard to "the scale of wages paid for similar kinds of work in other industries," and "the relation between wages and the cost of living," the Board has been under some difficulty. It is clear that the cost of living in the United States has increased approximately one hundred per cent since 1914. In many instances the increase to em-

ployees herein fixed, together with prior increases granted since 1914, exceed this figure. The cost of living and wages paid for similar kinds of work in other industries, however, differ as between different parts of the country. Yet standardization of pay for railroad employees has proceeded so far and possesses such advantages that it was deemed inexpedient and impracticable to establish new variations based on these already variable conditions.

It has been found by this Board generally that the scale of wages paid railroad employees is substantially below that paid for similar work in outside industry, that the increase in living cost since the effective date of General Order 27 and its supplements has thrown wages below the pre-war standard of living of these employees and that justice as well as the maintenance of an essential industry in an efficient condition require a substantial increase to practically all classes.

During the hearings, the "International Association of Railroad Supervisors of Mechanics," and "The American Train Dispatchers' Association" have been made parties to this dispute. In granting hearings to them, this Board has not assumed or decided any question of jurisdiction between the several organizations or associations either parties to or outside of this dispute.

The Board assumes as the basis of this decision the continuance in full force and effect of the rules, working conditions and agreements in force under the authority of the United States Railroad Administration. Pending the presentation, consideration and determination of the questions pertaining to the continuation or modification of such rules, condition and agreements no changes therein shall be made except by agreement between the carrier and employees concerned. As to all the questions with reference to the continuation or modification of such rules, working conditions and agreements, further hearings will be had at the earliest practicable date and decision thereon will be rendered as soon as adequate consideration can be given.

After giving the names of the various railroads affected, the decision outlines in detail the increases in wages, which are as follows:

ARTICLE II.—CLERICAL AND STATION FORCES.

Add to the rates established by or under the authority of the United States Railroad Administration for each of the hereinafter named classes, the following amounts per hour:

- Sec. 1. Storekeepers, assistant storekeepers, chief clerks, foremen, subforemen and other clerical supervisory forces.....13 cents.
- Sec. 2. Clerks with an experience of one (1) or more years in railroad clerical work, or clerical work of a similar nature in other industries, or where their cumulative experience in such clerical work is not less than one (1) year.....13 cents.
- Sec. 3. Clerks whose experience as above defined is less than one (1) year, and until an experience of one (1) year in such work entitles them to the increase provided for in Section 2.....6½ cents.
- Sec. 4. Train and engine crew callers, assistant station masters, train announcers, gatemen and baggage and parcel room employees (other than clerks).....13 cents
- Sec. 5. Janitors, elevator and telephone switchboard operators, office station and warehouse watchmen, and employees engaged in assorting way bills and tickets, operating appliances or machines for perforating, addressing envelopes, numbering claims and other papers, gathering and distributing mail, adjusting dictaphone cylinders and other similar work....10 cents.
- Sec. 6. Office boys, messengers, chore boys and other employees under eighteen years of age, filling similar positions, and station attendants....5 cents.
- Sec. 7. Station, platform, warehouse, transfer, dock, pier, store-room, stockroom and team-track freight handlers or truckers, and others similarly employed.....12 cents.
- Sec. 8. The following differentials shall be created or maintained, as the case may be, between truckers and the classes named below:
 - (a) Sealers, scalers and fruit and perishable inspectors, one (1) cent per hour above truckers' rates as established under Section 7.
 - (b) Stowers or stevedores, callers or loaders, locators and coopers, two (2) cents per hour above truckers' rates as established under Section 7.

The above shall not operate to decrease any existing higher differentials. Sec. 9. All common laborers in and around stations, storehouses and warehouses, not otherwise provided for.....8½ cents.

ARTICLE III.—MAINTENANCE OF WAY; UNSKILLED FORCES

Add to the rates established by or under the authority of the United States Railroad Administration, for each of the hereinafter named classes, the following amounts per hour:

Sec. 8. Laborers employed in and around shops and roundhouses, such as engine watchmen and wipers, fire builders, ash-pit men, flue borers, coal passers (except those coming under the provisions of Article VIII, Section 3, this decision), coal chute men, etc.....10 cents.

ARTICLE IV.—SHOP EMPLOYEES

Add to the rates established by or under the authority of the United States Railroad Administration, for each of the hereinafter named classes, the following amounts per hour:

Sec. 1. Supervisory forces13 cents. Sec. 2. Machinists, boilermakers, blacksmiths, sheet metal workers, electrical workers, carmen, moulders, cupola tenders and coremakers, including those with less than four years' experience, all crafts.....13 cents. Sec. 3. Regular and helper apprentices and helpers, all classes.....13 cents. Sec. 4. Car cleaners5 cents.

ARTICLE V.—ESTABLISHES NEW RATES FOR TELEGRAPHERS, TELEPHONERS AND AGENTS.

ARTICLE VI.—ENGINE SERVICE EMPLOYEES

Add to the rates established by or under the authority of the United States Railroad Administration, for each of the hereinafter named classes, the following amounts per mile, per hour, or per day, as the case may be, except in Section 4, as noted:

SEC. 1.—PASSENGER SERVICE.

Table with 3 columns: Class, Per mile, cents, Per day. Rows: Engineers and motormen (.8, \$0.80), Firemen (coal or oil) (.8, .80), Helpers (electric) (.8, .80)

SEC. 2.—FREIGHT SERVICE

Table with 3 columns: Class, Per mile, cents, Per day. Rows: Engineers (steam, electric or other power) (1.04, \$1.04), Firemen (coal and oil) (1.04, 1.04), Helpers (electric) (1.04, 1.04)

SEC. 3.—YARD SERVICE

Table with 3 columns: Class, Per hour, cents. Rows: Engineers (18), Firemen (coal or oil) (18), Helpers (electric) (18)

SEC. 4.—HOSTLER SERVICE

Note.—Superseding rates established by or under the authority of the United States Railroad Administration, and in lieu thereof, for each of the hereinafter named classes, the following increased rates are established:

Table with 3 columns: Class, Per day. Rows: Outside hostlers (\$6.24), Inside hostlers (5.60), Helpers (5.04)

ARTICLE VII.—TRAIN SERVICE EMPLOYEES

Add to the rates established by or under the authority of the United States Railroad Administration, for each of the hereinafter named classes, the following amounts per mile, per day, or per month, as the case may be, except in Section 4, as noted:

SEC. 1.—PASSENGER SERVICE

Table with 4 columns: Class, Per mile, cents, Per day, Per Month. Rows: Conductors (.67, \$1.00, \$30.00), Assistant conductors or ticket collectors (.67, 1.00, 30.00), Baggage men handling both express and dynamo (.67, 1.00, 30.00), Baggage men operating dynamo (.67, 1.00, 30.00), Baggage men handling express (.67, 1.00, 30.00), Baggage men (.67, 1.00, 30.00), Flagmen and brakemen (.67, 1.00, 30.00)

SEC. 2.—SUBURBAN SERVICE (EXCLUSIVE)

Table with 4 columns: Class, Per mile, cents, Per day, Per Month. Rows: Conductors (.67, \$1.00, \$30.00), Ticket collectors (.67, 1.00, 30.00), Guards performing duties of brakemen or flagmen (.67, 1.00, 30.00)

SEC. 3.—FREIGHT SERVICE

Table with 4 columns: Class, Per mile, cents, Per day. Rows: Conductors (through) (1.04, \$1.04), Flagmen and brakemen (through) (1.04, 1.04), Conductors (local or way freight) (1.04, 1.04), Flagmen and brakemen (local or way freight) (1.04, 1.04)

SEC. 4.—YARD SERVICE

Note.—Superseding rates established by or under the authority of the United States Railroad Administration, and in lieu thereof, for each of the hereinafter named classes, the following increased rates are established:

Table with 3 columns: Class, Per day. Rows: Foremen (\$6.96), Helpers (6.48), Switchtenders (5.04)

ARTICLE VIII.—STATIONARY ENGINE (STEAM) AND BOILER ROOM EMPLOYEES

Add to the rates established by or under the authority of the United States Railroad Administration, for each of the hereinafter named classes, the following amounts per hour:

Sec. 1. Stationary engineers (steam).....13 cents. Sec. 2. Stationary firemen and engine room oilers.....13 cents. Sec. 3. Boiler room water tenders and coal passers.....10 cents.

ARTICLE IX.—REFERS TO SIGNAL DEPARTMENT EMPLOYEES ARTICLE X.—ESTABLISHES NEW RATES FOR MASTERS, OFFICERS AND PILOTS OF RAILROAD FLOATING EQUIPMENT

ARTICLE XI.—OTHER SUPERVISORY FORCES

Add to the rates established by or under the authority of the United States Railroad Administration, for each of the hereinafter named classes, the following amounts per hour:

Sec. 1. Train dispatchers13 cents. Sec. 2. Yard masters and assistant yard masters.....15 cents.

ARTICLE XII.—MISCELLANEOUS EMPLOYEES

Add to the rates established by or under the authority of the United States Railroad Administration, for employees in the hereinafter named departments who are properly before the Board and not otherwise provided for, an amount (as per Section 3, Article XIII) equal to that established for the respective classes to which the miscellaneous classes herein referred to are analogous. The intent of this article is to extend this decision to a miscellaneous class of supervisors and employees, practically impossible of specific classification, and at the same time to insure to them the same consideration and rate increase as provided for analogous service.

ARTICLE XIII.—GENERAL APPLICATION

Sec. 1. The increases in wages and the rates hereby established shall be effective as of May 1, 1920, and are to be paid according to the time served to all who were then in the carriers' service and remained therein, or who have since come into such service and remained therein.

Sec. 2. The provisions of this decision will not apply in cases where amounts less than thirty dollars (\$30.00) per month are paid to individuals for special service which takes only a portion of their time from outside employment or business.

Sec. 3. Increases specified in this decision are to be added to the hourly rates as established by or under the authority of the United States Railroad Administration for employees now being paid by the hour. For employees paid by the day, add eight times the hourly increase specified to the daily rate. For employees paid by the month, add two hundred and four (204) times the hourly rate specified to the monthly rate.

Sec. 4. Each carrier will in payment to employees on and after August 1, 1920, include therein the increases in wages and the rates hereby established.

Sec. 5. The amounts due in back pay from May 1, 1920, to July 31, 1920, inclusive, in accordance with the provisions of this decision, will be computed and payment made to the employees separately from the regular monthly or semi-monthly payments, so that employees will know the exact amount of their back payments:

Recognizing the clerical work necessary to make these computations for back pay and the probable delay before the entire period can be covered, each month, beginning with May, 1920, shall be computed as soon as practicable, and as soon as completed, payment shall be made.

Sec. 6. The increases in wages and the rates hereby established shall be incorporated in and become a part of existing agreements or schedules.

Sec. 7. Except as specifically modified herein, the rules regulating payments of overtime or working conditions in all branches of service, and the established and accepted method of computing time and compensation thereunder, shall remain in effect until or unless changed in the manner provided by the Transportation Act, 1920.

Sec. 8. It is not intended in this decision to include or fix rates for any officials of the carriers affected except that class designated in the Transportation Act of 1920, as "Subordinate Officials," and who are included in the act as within the jurisdiction of this Board. The Act provides that the term "Subordinate Officials" includes officials of carriers of such class or rank, as the Interstate Commerce Commission shall designate by regulation duly formulated and issued. Hence, whenever in this decision words are used, such as "foremen," "supervisor," etc., which may apply to officials as are now or may hereafter be defined and classified by the Interstate Commerce Commission as such subordinate officials.

ARTICLE XIV.—INTERPRETATION OF THIS DECISION

Sec. 1. Should a dispute arise between the management and the employees of any of the carriers as to the meaning or intent of this decision, which cannot be decided in conference between the parties directly interested, such dispute shall be referred to the United States Railroad Labor Board in the manner provided by the Transportation Act, 1920.

Sec. 2. All such disputes shall be presented in a concrete joint signed statement setting forth: (1) the article of this decision involved, (2) the facts in the case, (3) the position of the employees, and (4) the position of the management thereon. Where supporting documentary evidence is used it shall be attached in the form of exhibits.

Sec. 3. Such presentations shall be transmitted to the Secretary of the United States Railroad Labor Board, who shall place same before the Board for final disposition.

By order of the Chairman.

The representatives of the labor organizations held sessions after the award was announced, but were unable to come to an agreement regarding the action to be taken. Five of the organizations accepted the award outright. Of the shop crafts unions the Railway Employees Department of the American Federation of Labor referred the award to the employees without recommendation. The Sheet Metal Workers' International Alliance, the Brotherhood of Maintenance of Way Employees and Railway Shop Laborers, the Brotherhood of Railway Car Men of America, the International Brotherhood of Electrical Workers, the International Brotherhood of Boiler Makers, Iron Ship Builders and Helpers of America, and the International Brotherhood of Blacksmiths, Drop Forgers and Helpers referred it to the membership and recommended its acceptance.

CONSTRUCTION OF STEAM HOSE

Earlier Data Contradicted. Tests Show Duck with Braid Inferior to Duck Alone. Seamless Tube Best

AT the 1919 convention of the American Society for Testing Materials there was presented a paper on steam hose for car heating by H. J. Force.* This paper discussed tests of hose made from duck alone and from duck with one or more layers of braiding, and also compared the service of machine-made tubes with three-ply calendered tubing. As a result of these tests the author recommended that steam hose should be made of a composition of duck and braid and that the machine-made tubes should not be used, tubing of three-ply calender being applied in every case on hose which is to be subjected to any considerable degree of temperature.

At the convention of this association held in June, 1920, John M. Bierer, in a paper on the construction of steam hose, described three series of tests which also compared the effect of differences in the tube and fabric. The conclusions reached by the three investigators are opposed to those given in Mr. Force's paper. A summary of the paper by Mr. Bierer is given below.

Steam hose can be constructed with a seamless machine-made tube, or with a tube plied from calendered stock. Furthermore, the hose can have for its fabric element a duck of given weight and number of plies or a combination of plied duck and one or more plies of braid. To determine whether it is more satisfactory both to user and to manufacturer to make a seamless or a plied tube, and to make a simple multiple-ply duck construction or a combination duck and braid construction, three series of tests, carried out individually and independently by the B. F. Goodrich Co., the Goodyear Tire and Rubber Co., and the Boston Woven Hose and Rubber Co., have been made, the results of which are here shown.

The actual steam hose tested by the three investigators was obviously of different material, particularly as to compounds, so it is enlightening to survey the different series separately in order not to make the materials a factor in any comparison of constructions.

The tests by the B. F. Goodrich experimenters endeavored to compare both seamless with plied tubes and simple duck

with duck-braid construction. All samples were $1\frac{5}{8}$ in. in inside diameter, with tube $\frac{1}{8}$ in. thick, cover 1-32 in. thick, duck 20 oz. per sq. yd., and braid 12 2-3 yarn. The hose was tested in a vertical position (so as not to have condensed steam present), under intermittent steam pressures, ten hours under pressure and two hours rest, until failure.

The results of the Goodrich tests are summarized in Table I. Each result represents an average of five individual samples of each construction.

Sample B was of distinctly lighter weight than A or C, so it is not surprising that failure occurred earlier than the A and C samples, which were comparable to each other. C and D were different only in the construction of tube, so that the longer service of C was undoubtedly due to the absence of seams, joints, or plied surfaces, which tend to open up. Similarly, A and C were different in fabric construction, with the same tube, so that the better endurance of C can safely be laid to the superiority of the simple plied-duck to the braid and duck construction.

It takes little studying of these experiments to notice two facts already known to many familiar with steam hose. The steam hose with seamless tube lasted about half again as long as that with a plied tube; and likewise the hose with simple duck of sufficient plies lasted about half again as long as the hose with a combination of duck and braid.

Summarizing the experiments of the Goodyear Tire and Rubber Co., there appears a series of similar results. Table

TABLE I.—RESULTS OBTAINED IN TESTS BY B. F. GOODRICH CO.

	Sample			
	A	B	C	D
Number of plies of duck.....	3	4	6	6
Number of plies of braid.....	2	0	0	0
Tube	Seamless	Seamless	Seamless	Plied
Endurance under 60-lb. pressure, hours	2,261	904	3,143	2,170

II represents an average of five individual samples of each construction. Comparison is offered in this series also of seamless and plied tubes, of duck and duck-braid constructions, and of expansion and contraction measurements as well. Like the Goodrich tests, the hose was tested ten hours

*See *Railway Mechanical Engineer* for September, 1919, page 527.

under 60 lb. steam pressure and two hours rest until failure.

Owing to details of manufacture, there is necessarily not found the same percentage ratios of endurance among the various constructions that were found in the Goodrich tests, but inspection of the results will reveal certain facts more important than this detail. The hose with the seamless tube *C* outlasted that with the plied tube *D* and the hose with the simple plied duck construction *C* outlasted that with a combination of duck and braid *E*. These results, though not so strikingly shown, are in accordance with those obtained in the Goodrich experiments. A further feature should be noted, that though the expansion in lateral dimensions and contraction in length are favorable to the duck-braid construction, the difference is so small between the two styles that any real and practical superiority for the braided hose would be negligible in practice.

The next experimental data to show divergence among the constructions are those obtained at the Boston Woven Hose and Rubber Co. laboratories. In order to determine the relative value of a hose with simple plied duck and hose with a combination of duck and braid, and to determine the relative value of seamless tubes and plied tubes, the following constructions were given prolonged tests. All

TABLE II.—RESULTS OF EXPERIMENTS OF GOODYEAR TIRE AND RUBBER CO.

	Sample				
	A	B	C	D	E
Number of plies of duck	2	4	6	6	3
Number of plies of braid	2	0	0	0	2
Tube	Seamless	Seamless	Seamless	Plied	Seamless
Endurance under 60-lb. pressure, hours	1,506	1,198	1,624	1,493	1,612
Expansion of diameter in 1,000 hours, per cent	6.1	12.2	8.2	8.1	7.0
Contraction in length in 1,000 hours, per cent	1.6	3.2	3.7	3.6	1.8

hose was of 1-in. inside diameter $\frac{1}{8}$ -in. tubes, 0.050-in. covers and was tested in 3-ft. lengths. Two series of tests were carried out: the first at 60-lb. steam pressure intermittently 124 hours on and 44 hours rest, the second continuously at 180-lb. pressure, both until failure. Eight individual samples were tested in each series and the results summarized are an average of these:

For a given fabric construction, hose with seamless tubes *A* lasted about one-fifth again as long and *B* almost twice as long as those with plied tubes *C* and *D*. Furthermore, for the same style of tube, hose with simple plied duck *A* lasted half again as long, and *C* over twice as long as those with duck and braid construction *B* and *D*.

In these tests, owing to particularly careful workmanship on the samples, failure was not due primarily to separation of the seam or joint on the inner surface of the tube. But in the ordinary process of manufacture, without such undue care and special attention, the plied tube is always a danger, and this splitting and opening up of the tube is practically

TABLE III.—RESULTS OBTAINED BY THE BOSTON WOVEN HOSE AND RUBBER CO.

	Sample			
	A	B	C	D
Number of plies of duck	6	3	6	3
Number of plies of braid	0	2	0	2
Tube	Seamless	Seamless	Plied	Plied
Endurance under 60-lb. intermittent pressure, hours	2,607	1,770	2,143	950
Endurance under 180-lb. constant pressure, hours	67	26	62	17

a fatal objection to the success of any hose by this method. This series is a clear case of superiority of seamless tubes over plied tubes, and of simple plied duck over a combination duck and braid construction.

Conclusions

Three different experimental laboratories, working individually and independently, found consistent results in an effort to determine the relative values of seamless and plied tubes, and of simple duck and duck supplemented by braiding. From the data gathered, there are two conclusions concerning these relative values which are obvious and irrefutable:

1. Steam hose made with seamless tubes (in practice by the tube-machine method) is superior in endurance under steam pressure to hose with tubes made up of successive plies of a sheeted stock, sometimes known as a calendered tube. The hose with plied tubes was found to fail by the splitting and separation of the seam necessarily formed at the surface of the tube in its construction.

2. Steam hose with its fabric constructed of successive plies of frictioned duck is superior in endurance to, and the practical equal in expansion and contraction of, hose made of a fewer number of plies of duck supplemented by plies of braiding.

The inevitable conclusion must be that it is most advantageous to the user and to the manufacturer alike to construct steam hose with a seamless tube and for its fabric element sufficient number of plies of duck only.

CHANGES IN THE RULES OF INTERCHANGE

The following modifications in the Rules of Interchange have been approved by the Executive Committee of the American Railroad Association and issued as Circular S III—163.

Effective March 1, 1920, all modifications of these rules having special application only to railroads under U. S. Federal control are cancelled, being superseded by the General Rules.

Rule 3.—The effective date of Section (d) of this rule has been extended to October 1, 1922, and the rule modified to read as follows:

Cars built prior to October 1, 1915, will not be accepted in interchange after October 1, 1922, unless equipped with A. R. A. Standard axles.

The effective date of Section (i) of Rule No. 3 has been extended until October 1, 1922, and the rule modified to read as follows:

After October 1, 1922, no cars with trucks of less than 60,000 lb. capacity will be accepted in interchange unless equipped with wooden or metal draft arms extending beyond body bolster, metal draft arms integral with body bolster, metal draft arms extending to body bolster and securely riveted to same, or transom draft gear.

Effective August 1, 1920, Rule 93 is modified to read as follows:

Separate bills shall be rendered for cars destroyed.
Separate bills shall be rendered for the periodical repacking of journal boxes.

All charges for repairs made to cars on account of owner's defects, defect cards and rebuttal authorities shall be consolidated against any one company into one bill; however, separate bill shall be rendered for the period subsequent to February 29, 1920.

Separate statements to be made.
1. For owner's defects for each calendar month.
2. For all charges based on defect card, including rebuttal charges.

Note.—Totals only of these statements to be shown on the recapitulation.

The title and address of the officer to whom correspondence should be forwarded relative to exceptions to charges should appear on the bill.

This circular should be considered as a supplement to the Rules of Interchange, and necessary instructions issued to all concerned. These modifications to the Rules of Interchange will be incorporated in the next supplement issued to these rules.

THE TYPE "D" COUPLER IN PASSENGER SERVICE

Difficulties Involved in Its Application; How the Problem Was Solved on New Pullman Cars

THE first application of the standard Type "D" coupler to passenger equipment has been made by the Pullman Company on the new sleeping cars which are now being built at a rate to approximate an output of about 600 cars a year. Adaptation of the Type "D" coupler to passenger cars, without alteration from its standard form as designed for freight service, involves considerable difficulty, its large over-all dimensions causing it to interfere with the standard location of the train pipe connection. The trouble occurs on the knuckle or operating side of the coupler, which at its widest point extends about $7\frac{3}{4}$ in. from the center line of the stem.

The standard location of train pipe connections requires a distance of 20 in. between the center of the connection for the signal hose and that for the steam hose, with the steam hose connection $9\frac{1}{2}$ in. from the center line of the car. With the steam-heat connection but 12 in. back of the inside face of the coupler knuckle, it will be seen that with the draft gear

valve would tend to shorten the distance between the brake and signal hose connections and increase the distance between the steam hose connections on the adjoining ends of coupled cars. This condition, combined with certain conditions encountered in curving, would tend to cause the coupled steam hose to raise and separate the air hose couplings.

The solution finally arrived at by the Pullman Company and worked out for application on the sleeping cars now being built, is shown in the illustrations. Essentially this scheme involves the maintenance of a fixed relation between the center line of the coupler shank and the pipe connections, the latter being carried with the coupler in its lateral motion. This was accomplished by the design of a special coupler carrier casting with a long bearing face on which was placed a sliding saddle carrying the coupler and the ends of the train pipes. The bearing surface of the coupler carrier cast-

Application of the Type "D" Coupler to Pullman Cars

compressed there is very little clearance between the steam end valve and the side of the coupler when the coupler stem is on the center line of the car. This clearance is entirely inadequate to take care of the lateral swing of the coupler in curving. To increase the distance of the steam hose connection from the center line of the coupler would require a corresponding decrease in the distance from the center line of the coupler to the brake and signal hose connections, as the total distance between the two sets of connections is fixed and cannot be varied without requiring an entire readjustment of hose lengths. To move these connections over, however, in order to increase the clearance between the coupler and the steam end

ing has a width of $4\frac{3}{4}$ in. and a total length of $38\frac{1}{2}$. The coupler saddle casting is 29 in. long.

Between the top and bottom flanges of the I-section of the carrier casting the web member is omitted for a distance of 20 in. at the center to accommodate a centering spring and followers. With the spring and followers inserted, the saddle casting is placed over the carrier casting, pockets in the sides of the saddle being provided for the ends of the followers. The single coil spring is assembled with an initial load of 200 lb. and has a full load of about 600 lb. under the maximum travel of the saddle of $5\frac{1}{2}$ in. either way from the center. The coupler stem has a clearance of $\frac{3}{4}$ in. on either

side from the vertical retaining faces of the saddle casting to take care of the angularity of the stem with relation to the saddle under maximum lateral movement.

Both the carrier and saddle casting are relieved of lateral strains by the design of the platform and casting, which extends out at either side of the coupler shank to provide lateral stops. The coupler carrier is a steel casting while the saddle is of malleable iron with a movable shoe to take the wear of the coupler stem.

Brackets for support of the brake, signal and steam heat pipes are cast integral with the saddle casting. The brake and signal pipes are fastened with a single clamp which holds them rigidly in place. The steam pipe clamp is designed to close without tightly gripping the pipe, in order to provide for longitudinal expansion.

One of the problems which had to be solved in developing this arrangement was the provision of the necessary flexi-

the outside and inserting it inside the steel pipe connection, the difference in expansion of the two metals thus tightening instead of loosening the joint.

Probably the most difficult problem encountered in working out the details of the flexible pipe arrangement was that of providing a satisfactory mechanism for operating from inside the vestibule the movable steam heat end valve. The device by which this is accomplished is simple, self-contained, and requires little special care in locating it on the car to insure freedom of operation. The motion of the vertical operating shaft is transmitted to the valve through bevel gears to a horizontal sliding shaft of square section. The cored hole through the hub of the lower gear is tapered from its smallest section in the middle toward each end, thus providing for considerable angular movement as well as the longitudinal movement of the horizontal shaft, to take care of the effect of expansion and contraction of the steam pipe, the lateral

End View of a Pullman Car With Type "D" Coupler Application

bility in the pipes to permit the required amount of lateral motion. The air pipes offered no particular difficulty, as it was found that by locating the first clamp a distance of 9 ft. 8½ in. from the end of the car sufficient flexibility was provided in the pipe itself to take up the lateral motion without undue stress. Inasmuch as there are two rigid clamps between the end of the car and the first pipe joint no trouble is anticipated in maintaining tight train lines.

It was found, however, that the 2-in. steam heat pipe was too large to take up the lateral motion without unduly stressing the joints and making it impossible to keep them tight. A Barco universal joint was therefore inserted in the pipe at a distance of about 7 ft. 6 in. back of the end valve. One of the interesting problems encountered in this connection was the difficulty of maintaining a tight joint between the end of the pipe and the bronze ball joint member. This was overcome by threading the end of the ball joint member on

movement of the end and slight variations in the relationship of parts in assembling.

The lower end of the vertical shaft is also square in section and is tapered where it is inserted in the upper gear. To eliminate the necessity for precision in locating the gear casing with relation to the opening in the vestibule floor, this shaft is provided with a universal joint so that slight inaccuracies of alignment are taken care of without causing the parts to bind.

With the exception of the shafts, the parts of the device are all malleable castings and only such finish is provided for as is necessary to secure proper working alignment of the gears. The casing is made in three pieces, one of which is cast integral with the bracket by which the device is attached to the brake step. The gears are provided with finished hubs which have their bearings in reamed or drilled holes in the casing.

BOX CARS FOR THE CUBA RAILROAD

Forty Ton Capacity Single Sheathed Steel Frame Equipment of Exceptionally Strong Construction

CAR equipment for foreign railways is usually of interest by reason of the divergence from American standards of design. However, the Cuba Railroad has recently put into service some box cars which in strength and general design compare favorably with similar types in this country. These cars were designed and built by the American Car & Foundry Company. The first lot was recently completed and an additional order is now under construction. The cars are of the single sheathed type with steel underframes and steel superstructure. The nominal capacity is 36,400 kilos, or 80,247 lb., and the length over the end sills is 38 ft. 0 in. The light weight is approximately

and 21 in. wide is riveted over the greater portion of the center sill, extending to a point approximately over the center of the draft gear. The body bolsters consist of two $\frac{1}{4}$ -in. pressed steel diaphragms with 3-in. flanges all around, spaced six inches apart. Each bolster is reinforced at the top by a 12-in. by $\frac{3}{8}$ -in. cover plate, extending a short distance beyond the side bearings, and at the bottom by a 13-in. by $\frac{3}{8}$ -in. plate, extending the full width of the car. The bolsters have cast steel center plates and center fillers and malleable iron side bearings. The top of the bolster slopes downward from the center sill and the top of the side sill is $1\frac{3}{8}$ -in. lower than the top of the center sill. The side

End Elevation and Sections of 40-Ton Box Car for Cuba Railroad.

40,000 lb. The car body is 36 ft. $6\frac{7}{8}$ in. long inside, the inside height and width being 7 ft. $5\frac{1}{4}$ in., and 8 ft. 6 in., respectively.

Underframe

The underframe is built up of rolled shapes and plates, comparatively few pressed steel parts being used. The center sill is of the fishbelly type, consisting of two steel side members continuous between the end sills. They are made of $15\frac{1}{16}$ -in. plates with top chords of $3\frac{1}{2}$ -in. by $3\frac{1}{2}$ -in. by $5\frac{1}{16}$ -in. angles and bottom chords of 5-in. by 4-in. by $\frac{5}{8}$ -in. angles with the long flanges placed horizontally. The sills are $24\frac{3}{4}$ in. deep for a length of 10 ft. 4 in. at the center and taper to 15 in. deep just inside of the body bolsters. The web plates are reinforced vertically with 4-in. by 3-in. by $\frac{1}{4}$ -in. angles. A steel top cover plate $5\frac{1}{16}$ in. thick

sill is of 8-in. $16\frac{1}{4}$ -lb. channel section and extends continuously from end sill to end sill.

There are two crossbearers, spaced 9 ft. $3\frac{1}{2}$ in. apart. Each consists of a $\frac{1}{4}$ -in. pressed open hearth steel diaphragm, flanged three inches wide on all sides. A filler of similar construction is placed between the center sills. The crossbearer is reinforced at the top and bottom with a 3-in. by $2\frac{1}{2}$ -in. by $5\frac{1}{16}$ -in. rolled steel angle. The top cover plate is 8 in. by $\frac{1}{2}$ in. and extends through the center sill web plates. The bottom cover plate is 8 in. by $\frac{7}{16}$ in. and extends continuously from side sill to side sill, passing under the center sill.

At the center of the car and midway between the body bolsters and crossbearers there are floor beams consisting of 6-in., 8-lb. channels, secured to the side and center sills by

means of the vertical stiffening angles, and also by pressed angle connections, as shown in the sectional drawing. The end sills are 12-in., 20½-lb. channels and extend straight along the full section for the entire width of the car. A 5-in., 6½-lb. channel extends from the corner of the body bolster and center sill to the corner of the car, where it is attached to the side sill and end sill by means of flanged gusset plates. The draft gear is of the Cardwell friction type with Sharon

and crossbearers, extending continuously between the end sills, the sections at the bolsters being arranged as shown in the drawing. There are three stringers on each side of the car and to them is secured the flooring, which is 1¾-in. by 7¼-in. yellow pine, ship lapped. Two and one-quarter inch beveled grain strips are applied at the sides and ends.

The side doors, which have a clear opening of six feet,

couplers operated by the American Car & Foundry Company's direct-connected top operating uncoupling device.

Superstructure

Both the vertical and horizontal intermediate members of the side truss are 3-in., 8½-lb. Z-bars, securely riveted to the side sill and to the side plate, which is a 5-in. by 3-in. by 5/16-in. angle with the short flange extending outward.

are constructed of 13/16-in. yellow pine, tongued and grooved, with a 13/16-in. pine frame. The outside frame and crossbar are steel angles. The doors are fitted with Camel Company door fixtures, including bottom rollers, door starter and burglar-proof lock. Handholds, ladders and sill steps are all in compliance with the requirements of the federal safety appliance laws and the standards of the American Railroad Association.

Trucks

The trucks are of the rigid diamond arch bar type with 5-ft. 4-in. wheel base, having cast iron wheels and A. R. A. standard journal boxes. The bolsters are of cast steel with the center plate cast integral and are fitted with Stucki roller side bearings. The spring plank is pressed steel of channel section. Ajax No. 2 brake beams are used.

These cars were shipped on their own wheels, being sent to Key West over the Florida East Coast and transferred to Cuba on the car ferry operated by that road.

The door posts are 5-in., 11.6-lb. Z-bars. A pressed steel section attached to the flange of the side plate serves as reinforcement over the door opening and also as weather protection for the door. The side sill is reinforced under the door opening by a 5¾-in. by 3¾-in. by 5/16-in. bent angle. The corner posts are 5-in. by 4-in. by 3/8-in. rolled steel angles and are secured to the side sill by means of bent angle clips. At the upper end they are riveted to the side plate

WHEN TO HEAT WOOD BEFORE GLUING*

Whether a hide glue joint will be strengthened or weakened by heating the wood before gluing depends on the size of the joint. If the joint to be made is of small area, heating the wood is unnecessary. In fact, it may be detrimental, for the warmth of the wood will keep the glue thin; and, when pressure is applied, too much glue may squeeze out, leaving a starved joint. It is easy to apply too much pressure.

In making glue joints of large size (several inches each way), heating the wood before gluing is of distinct advantage. Many experiments at the Forest Products Laboratory, Madison, Wis., have proved that when the wood in large joint work is not heated the joints develop full strength only in spots. Weak spots and even open joints are too frequently discovered. Uniform high strength in joints of large size may be secured by heating the wood in a hot-box for 10 or 15 minutes at 120 to 130 deg. F. just before gluing. The heat from the wood prevents the glue from chilling.

It should be remembered that heating the wood retards the setting of the glue to some extent. In heavy woods, from which the heat escapes slowly, this retarding effect is more marked than in lighter woods. In all species glued cold at the laboratory the time under pressure required to develop full joint strength was less than eight hours. When heated wood was used at least 10 hours were required to develop full joint strength in mahogany, and over 12 hours in oak and maple.

and the end plate, which is of ¼-in. steel plate, shaped to suit the roof. There are two Z-bar end posts of 4-in. 12½-lb. section. Between the end posts, directly below the running board brackets, is placed a Wine shutter type ventilator. The steel car lines are riveted directly to the side plate.

The side lining is 1½-in. by 5⅞-in. tongued and grooved yellow pine bolted to the steel frame. Floor stringers of 5-in. by 3½-in. yellow pine are applied over the floor beams

*Technical note No. 92, Forest Products Laboratory, U. S. Forest Service, Madison, Wis.

THE INSPECTION OF FREIGHT EQUIPMENT

Special Conditions Affecting the Loading of Cars and the Handling of Fast Freight Trains

BY L. K. SILLCOX

Assistant General Superintendent Motive Power, Chicago, Milwaukee & St. Paul

TO THE END that non-serviceable cars be kept off our line, car inspectors at interchange points will be careful to see that foreign cars coming from connecting lines are in good running order and otherwise fit for loading for which cars are intended.

When system cars are received in interchange with wrong repairs, car foremen will arrange for joint inspection being made and a joint evidence card being properly filled out and signed. This joint evidence card is to be forwarded to the master car builder's office with a bill, to cover correction of the wrong repairs. If the wrong repairs are not corrected at the time, the joint evidence card is to be securely tacked to outside face of the intermediate sill or on the cardboard on the center sill of all-steel cars. When wrong repairs are finally corrected the card may be removed and attached to a bill and forwarded immediately to the master car builder's office.

Cars Placed for Loading, Inspection and Repairs

It is of special importance that careful inspection be given and proper repairs made to cars before they are placed for loading to insure their being in good serviceable condition, as it should not be necessary to shop cars out under load before arriving at destination for defects that existed before being loaded. It is felt that no reasonable excuse can be given for placing a defective car for loading.

Light Repair Cars

When freight cars are shopped out for repairs, those needing the lighter repairs should be placed on repair tracks designated for such repairs so they will be promptly repaired and returned to service.

Marking Cars to the Repair Tracks Unnecessarily

In going over the railroad, it generally appears that at certain points insufficient attention is given light repairs to cars in yards. Many such cars when not handled in the yard are marked to the repair track, which is not only costly from a transportation standpoint, but also delays equipment and inflates the bad order statement.

It should be impressed upon all concerned that wherever possible, light repairs to cars should be made in yards and equipment ought not to be marked to the repair tracks for brake shoes, brake rods, packing, brasses, etc., when there is any possible way of doing this in the yard under blue flag protection.

When cars are shopped out by inspectors for minor repairs that can be made in transportation yards, the needed force should be provided so the cars can be promptly repaired, avoiding the necessity and cost of switching them to shop tracks.

The importance of this cannot be brought forcibly enough to the attention of all concerned. Certain stations show a sad lack of understanding in this direction. It should also be borne in mind that the journal box lids on freight trains must be opened at the principal inspection points, not only the lids on boxes that are easy to open, but also those that are more difficult. It means much to know whether the lubrication of the equipment is in fit condition and unless this precaution is taken there is bound to be continued difficulty.

Disposition of Unfit Cars

Instructions are issued giving automatic disposition and limit of expense for system owned freight cars. Unfit cars which come within the limits prescribed must be held for disposition as indicated and in order to show the true condition of affairs, the back of the No. 55 telegraph report is to contain the numbers and initials of foreign and system cars held for advice as to destruction or rebuilding. It is not economy to allow old unfit cars to continue in service causing good equipment to be damaged and broken up, and therefore these rules must be given the attention they deserve. Proper report of all cars destroyed or exchanged from one class to another must be made up as prescribed.

Shipping of System Freight Cars

It is not desired to ship bad order cars from one repair point to another, and no cars must be sent forward from one repair station to another without receiving written authority from the master car builder, assistant master car builder, or respective district general car forman's office. Violations of this rule will not be tolerated. Where bad order cars are sent from one station to another, they must be held on the originating station's bad order report, until such time as advice is received from the destination point, that they have received and will carry the cars. As a general rule, and in order to properly arrange material requirements, it is our practice to give preference to shipping system equipment in the following manner, concentrating on certain types to regularly meet the business:

January-February—Cabooses, Bunk Cars, Refrigerators.

March-April—Stock and Flour Cars.

May-June—Grain and Stock Cars.

July-August—Coal, Cinder and Merchandise Cars.

September-October—Logging. Flats and refrigerator Cars.

November-December—Ballast and Ore Cars.

Commodity Cards

The general practice of employing the use of commodity cards and boards is not wholly satisfactory unless very closely supervised. After cars have been loaded, these cards or boards should be removed as many suits for damage claims have been filed on the basis of information shown on rough freight cards or a leaky roof sign. Agents should be interested in giving this matter proper attention, also in removing explosive signs or cards when cars are emptied.

Obtaining Disposition of Foreign Equipment

It is intended that empty foreign cars in bad order on the railroad and which it is not considered advisable to repair, be written up for disposition promptly. Material required from owners for repairs to foreign cars on the railroad must be ordered just as quickly as possible so as not to hold cars unnecessarily. If action is not obtained within a 30 day period on either of the above items, and it causes any foreign car to be held in bad order more than 30 days, a telegram should be sent to the MCB office giving all particulars and data. If it happens to be that owners are dilatory the matter will be taken up with the executive of the owning line for immediate action. If cars stand around more than 30 days, let no effort be spared to get them moving.

Handling Charges for Repairing Foreign or Private Line Cars

Repairs of any kind to cars of foreign ownership, whether railroad, or privately owned, will be charged for in accordance with American Railroad Association rules, the latest price instructions to govern, all covered by the usual repair card. On cars of private ownership, or in cases where owners are not members of the association, charges will be made at actual cost and collection will be made by the agent, a complete record being kept and full advice sent to the master car builder in all cases so that proper accounting of these amounts may be insisted upon. In case repairs have to be made at any station where emergency trucks are not located, the necessary material will be obtained from the baggage car, or failing in this, such parts as desired can, if practical, be removed from the rear end of the rear car temporarily.

Transferring Bad Order Loads

Car foremen at all repair points will be considered the proper parties for authorizing the transfer of lading on any bad order car that cannot be repaired under load. Where additional help is required in order to carry out such transfer of lading, car foremen will take the matter up by wire, with the general car foreman or their immediate superior, stating necessity in detail. The higher officer in turn will request the superintendent to furnish the required number of men. This contemplates the entire abandonment of agents' forces or transferring being handled by contractors at any point on the system.

At the smaller stations, in case transferring is required on a valuable shipment, such as furniture, merchandise, machinery or finished and manufactured products, car foremen will call on the agent to break the seal and be in a position to verify that no unnecessary damage is done in the operation of transferring.

A weekly report of freight cars transferred or lading adjusted, must be made to the master car builder's office every Saturday night, and a copy sent to the general supervisor of transportation.

Line Clearance Diagram

The proper diagram should be posted at all inspection points for the instruction of inspectors, giving maximum clearance for loading which should be regarded with reference to offering cars in interchange at connecting points, also at originating points of loading. There has been a great deal of difficulty on account of being obliged to transfer loads on account of equipment not having proper clearance.

The car department must co-operate with agents on the system to the extent of cautioning them not to accept shipments wherein the clearance exceeds that stated. Agents will be able to check this matter to their own satisfaction, inasmuch as they are informed as to routing and billing.

All car foremen should co-operate to avoid having to transfer cars at connections on account of the limitations called for being exceeded and all should interest themselves in this matter. In case of doubt, the maximum clearance to pass all lines is a height of 12 ft. 6 in. and a width of 9 ft. 6 in., but most lines have a maximum height clearance of about 15 ft. and a width of 10 ft. 3 in.

Height to Load Grain in Cars

The following data have been worked up to show the maximum height to which a car may be loaded with grain depending on its inside length and width, based on the following weights:

Grain	Weight per Bushel, lb.
Wheat	60
Corn, rye or flax	56
Barley	48
Oats	32

Length inside	30 Ton Capacity Cars 8 ft. 6 in. Wide Inside			
	Wheat	Corn, Rye or Flax	Barley	Oats
31 ft. 0 in.	4 ft. 9 in.	5 ft. 1 in.	6 ft. 0 in.	8 ft. 0 in.
32 ft. 0 in.	4 ft. 7 in.	4 ft. 11 in.	5 ft. 9 in.	8 ft. 7 in.
33 ft. 0 in.	4 ft. 8 in.	4 ft. 9 in.	5 ft. 7 in.	8 ft. 4 in.
34 ft. 0 in.	4 ft. 4 in.	4 ft. 8 in.	5 ft. 5 in.	8 ft. 1 in.

Loading of Lumber on Open Top Cars

In the past there has been considerable trouble caused by carloads of lumber on flat and coal cars shifting, losing part of the load and making it necessary to set cars out to be re-staked and given considerable attention. This should be brought to the notice of agents and shippers should be advised that the M. C. B. rules governing the loading of lumber, piling, etc., on open top cars, must be carefully observed and cars must not be allowed to be forwarded in an unsafe condition. Stakes and wiring must be carefully examined and all precautions taken to see that there are enough of the stakes and that they are sufficiently strong to carry the load safely.

Inspectors must watch these shipments carefully and not allow a load to go forward until it is safe, and where one is found to be unsafe, it must be attended to properly, and a record taken as to where it was loaded and its destination, stating whether the staking, etc., is deficient so that the matter may be corrected at the initial loading point.

Bearing pieces, especially on wooden flat cars, must be placed over the bolsters, otherwise breakage of sills is bound to result.

Handling Gravel Ballast Cars

It is well to remember that open top cars loaded with sand and gravel become greatly overloaded in periods of rainy

weather. It has been determined that sometimes as much as 6,000 lb. additional load is encountered due to moisture absorbed and on this account all concerned are asked to guard in every reasonable way against overloading cars when such conditions prevail. System owned high side 30 ton gondolas are not to be used in gravel or ballast service, as they are not of suitable or strong enough construction.

Loading Ice in Refrigerator Cars

It should be thoroughly understood that in loading ice, refrigerator cars equipped with ice boxes must not be used in this traffic, owing to the damage resulting in the interior of the car.

Classification of Trains

A train may consist of an engine, or motor, or more than one engine, or motor, coupled with or without cars displaying markers.

A regular train is one authorized by a time-table schedule.

A section of a train obtains when running one or two or more trains on the same schedule, displaying signals, or for which signals are displayed.

An *extra train* is one not authorized by a time table schedule. It may be designated as—*Extra* for any extra train, except work extra; *Work Extra*—for work train extra.

There is in general a broad classification of trains constituting first class, which are passenger, second class, which are time freights, and third class, which are way freights. All extra trains and those for work service fall into their proper classification automatically.

Time Freight Runs

The success of a road as a freight-carrying line depends almost entirely on its reputation and ability to keep time freights close to their schedule. With this end in view, their movements have been specially plotted, showing the stopping points and standard classes of inspection required. Much depends on the careful planning of all men along the line, for there is hardly a single town of any size on the system which does not receive and supply loaded cars entering into the movement of time freight trains. It is only natural to suppose that the operating department are very anxious at all times to get these trains out of town and on their way with as little delay as possible. Foremen will be held responsible for seeing that cars are properly repaired at loading platforms, industries, etc., bad ordering such cars exhibiting serious defects and which cannot be fixed up in time to let them out for movement as intended on this account. Foremen should make such arrangements as to see that these cars when discovered are not loaded out, but sent empty to the repair track for attention. It is not a difficult matter to anticipate the movement of loads coming from connections, which are to form part of important time freight runs. Many times the shipment reaches us with a lot of delay, which must somehow be wiped out and shippers keep wiring us for delivery. All that we can do is to see that prompt businesslike attention is accorded. It is often very aggravating to have large parts of important trains turned over from connections requiring wheel renewals, repairs to air brake equipment, defective trucks and draft rigging. Some of this is due to rough handling through large terminals, or it may be that weak equipment has been employed. No loaded cars for important movement are allowed to proceed from gateway terminals, unless the following requirements are met, with this exception, that short draft timber cars, if loaded, may be placed to the number of ten per train ahead of the caboose. (A) If draft timbers are used they must extend at least 30 in. behind the center of the bolsters. (B) Cars having steel center sills running from end to end of car are satisfactory. (C) Cars of steel underframe, steel frames or all metal construction are satis-

factory. (D) Cars having short draft timbers in front of body bolsters must have the load transferred at gateway terminals and, if possible, the car is to be disposed of to the delivering line in a satisfactory manner, unless it is known that the car can be kept not more than ten cars ahead of the caboose, for the entire movement.

Too much cannot be said with respect to the importance of small repair stations along the line, watching diligently to see that unfit cars or equipment which has not received adequate attention are put in proper shape before being placed in important time freight trains. If the cars cannot be made suitable for the movement, they should not be released until the load is transferred, in the regular manner, as has been described.

Steel Trains, Silk Runs and Other Trans-Continental Movements

It often happens that there are special runs lasting for long periods, of commodities destined for export at the Pacific Coast, or imports coming from the Orient, Alaska and other parts of the world, or of similar character on other railroads than those operating in the northwest. These shipments are only maintained on our railroad to the extent of our being able to render better service than our neighbors. The secret of success in handling of such movements is to first know the characteristics and requirements of the service and to put the equipment in proper condition to start with so that it can make a successful run to its destination without a lot of delay intermediately due to defects which should have been previously discovered.

Logging, Lumber, Ice and Ore Trains

This type of train movement is more or less localized and yet important, in maintaining the good will, and necessarily the patronage, of the communities served. The requirements of service at the various points on the system are well known to local foreman. An active effort is absolutely essential and must be made at all times to keep the equipment in good shape to handle the business offered and avoid delays and disaster. Equipment in such service must be given periodical attention.

Meat, Fruit, Produce and Dairy Trains

Possibly the greatest problem in the movement of scheduled freight runs comes under these classifications. In the first place, the equipment going to make up these trains, makes more mileage than any other type, as it is kept in constant service; and this has a very definite effect on the ability of truck frames, wheels, and axles to withstand breakage due to fatigue of metal and crystallization. Boxes run hot due to the high speed maintained and the rocking load, especially in beef cars which, coupled with heavy superstructures, imposes tremendous strains on the running gear. The greatest possible temptation prevails to absorb lost time, often with disastrous results, for most of the shipments are of very perishable nature, and time is consumed not only in icing the equipment, but, in routes from California to New York in fruit runs, it is reasonable to suppose that many unforeseen conditions have to be met, not only operating, but mechanical and climatic. Experience has dictated a policy of starting the trains out in the best possible condition and all necessary repairs to be made at intermediate points, also where time is not allowed to give proper attention to defects, good judgment would dictate the cutting out of the car—and this must be done rather than take any chances. A careful check must be made to see that equipment in this service is not overlooked. The greatest pride should be centered in handling this difficult class of business promptly, successfully and safely. Wherever it can be arranged, cars must be gone over before being set for loading or at the time loading is going on.

Stock Trains

Certain sections of the railroad depend entirely, or, in a large part, on the ability to attract stockmen to ship over the line. Very certain and difficult competition has to be met. Besides this, one of the greatest opportunities offered for damage claims is accounted for from delay in getting stock to market on time, resulting in changing prices offered for stock at the primary markets, also delays mean extra feeds which burden the shipper with unwarranted expense. Defective equipment offered for loading should always be avoided, as there is plenty of time to fix stock cars properly during the idle season and at feeding stations, where they must necessarily lay five hours at least. This is a branch of the trade where we must deliver service, as the shipper has his representative on board to check up the movement.

The Federal law prohibits the movement of stock when such movement exceeds 36 hours, unless stock is unloaded for rest and feeding. It is therefore of the utmost importance that stock cars be given the best attention at originating stations and at feeding stations, so that the trains will be able to make their next stop without being delayed on account of defective equipment. The minimum layover at feeding stations is five hours.

Movement of stock trains is checked by government representatives, and in cases where the 36 hour law is violated, suits are brought against the road.

Primary movements will find their way to the stations, where the principal packing houses are located. Local car foremen are well acquainted with the necessities of the cars and must not only take into account movements which come to them from their neighboring foremen, but should take sufficient interest to see that when cars are returned they go into the loading territories in good order. In this sense the foremen can control their bad order situation and difficulties of movement through their territory to a very great extent. Too many foremen complain about their neighbors when they themselves had the same empty stock cars passing through their stations prior to being loaded and prior to returning to them in unfit condition under revenue load and allowed the cars to pass through their hands in defective condition and return in the same shape, necessitating delay to trains and oftentimes transfer of shipments. Further emphasis is necessary to point out that at feeding stations the minimum time allowed is five hours and the time between feeding stations is very much limited, due to shippers being unwilling to delay their stock and to go to the additional expense of extra feeds, which can be overcome if these trains are put in shape during the five hours allowed during the rest period. This must be done, and feeding stations are primarily responsible for the 36 hour movement of trains between feeding stations and consuming markets.

Work Trains

Proper co-operation and understanding with the operating department will do ever so much in providing for successful operation of work, gravel and ballast trains. Sufficient notice should be given in advance, so that opportunity may be taken to put cars in shape. Care should be exercised to be certain that the proper type of car is furnished; for instance, ballast cars should not be used where flat cars are wanted, resulting in the sides of ballast cars being torn off and wrecked, as has been done often in the past. Center plates should be well lubricated, side bearings free of each other, draft gear, brake and wheels in good order and lubrication, packing, brasses, wedges, boxes, covers and dust guards in perfect condition to render effective service. Overloading of cars is to be avoided.

Inspection of Trains

It is the duty of inspectors to see that the coupling pipe joints and all other parts of the brake apparatus are in good

order and free from leaks. For this purpose they must be tested at every opportunity and especially when air pressure is available. If a defect is discovered in the brake equipment of a car which cannot be held long enough to give time to correct such defect, the brake must be cut out and the car properly carded to call the attention of the next inspector to the repairs required, but, as stated elsewhere, the carding of this brake must be the last resort and every effort should be made to repair the defect before the car is allowed to proceed.

The smallest proportion of freight cars with the air brakes in good condition must be 85 per cent. In making up trains the couplings must be united and the cocks at the ends of the cars all open, except at the rear end of the last car, where the cock must be closed. The inspector must know that the air is passing through the pipes to the rear end and that the couplings are properly connected and free from leaks. After the train is fully charged, the engineer must be signalled to apply the brakes. When the brakes have been applied, they must be examined upon each car to see that they are applied and have the proper piston travel. This having been ascertained, the inspector must signal the engineer to release the brakes. He must then again examine the brakes upon each car to note that each is released. If any defect is discovered, it must be corrected and the testing of the brakes repeated until they are found to work properly. The inspector must then enter on form 975 the number of cars with brakes in good order. This examination must be repeated if any change is made in the make-up of the train before starting.

Inspectors should especially take advantage of the incoming freight terminal test as this is the logical time to locate the defects as they will then have ample time to repair them. When the engineer applies the brakes and then cuts off, the inspectors must make a rapid inspection of piston travel, marking on the side of the car with chalk those cars which have either short or long travel, but not stopping to adjust the brakes or make any other repairs at this time, making all necessary adjustments on the way back. In many yards where a train is made up the outgoing engine is not coupled on until the time of departure. When this occurs everyone is in great haste to get this train out of the yard and in many cases the air brake inspection is neglected, but this can be overcome to a great extent if after a train is made up and the switching is all done, air from a switch engine is secured to charge up this train. If this is done, when the outgoing engine is coupled on, there will be nothing else to be done but to charge up the brakes and then leave.

Train Release Inspection Certificate

The object of this form is to guarantee the proper inspection and safe condition of the equipment and to obtain the benefit of the train crews' experience with the trains while on the road. Any defects shown on this form must be properly corrected and the car inspector at the inbound station is to make certain that ample assistance is provided to correct any of the defects reported by the conductor on this form so that it will not be necessary for him in filling out this form for the outbound movement of the train to include any of the defects previously reported. This form is to be made out in duplicate, and the car inspector will hand the conductor in charge of the train leaving the station two blanks with carbon paper between, all placed on a suitable board and of same dimensions as the report and held in place by a rubber band near the top. On arrival of the train at the inbound station, the car inspector will meet the conductor and receive Form 975 and will note thereon the number of brakes cut-out and sign the report in the space provided for inbound movement signature. He will at this time note whether the brakes cut-out have air

brake defect cards attached. He will also look over the report to see whether the conductor has reported any difficulty with the train while in his possession and if any trouble is reported it must be corrected immediately. The original of the report must then be forwarded to the division superintendent and the duplicate retained by the local car foreman in charge of the station at which the train arrives. These copies must be kept in neat order so as to be readily accessible in the event it is desired to look up the record on any train arriving at the station. It should be understood that these reports are to be used on all divisions and are to cover the operation of a train from one terminal to the next terminal and where a train goes through several terminals, the car inspector will arrange to supply new forms to the conductor taking charge of train leaving station. In other words, the one form is not to be carried through from the originating station to the final terminal, but is to be carried only so far as each divisional terminal where train crews change.

Carding Cut-Out Brakes

The applying of air brake defect cards to cars on outgoing trains by inspectors must be the last resort. The necessary repairs must and can be made if the inspection is made at the proper time, i.e., on the arrival of trains. This defect card is primarily for the use of trainmen who often-times encounter a brake, while en route, that is causing them trouble and their only resource is to cut this brake out to enable them to get over the road. In order to expedite all repairs on this brake, they are furnished with an air brake defect card which they should attach to the crossover pipe, marking on this card the reason why the brake was cut out. On arrival at the terminal the inspectors and repair men must make every effort to repair the defect as carded. The only time when an inspector will be permitted to allow a car to proceed with the brake cut out and a defect card attached will be when under no circumstances could this car be held to make the necessary repairs, such as in manifest freight service. Cars arriving in yards with brakes cut-out and no cards attached should be reported to the foreman in charge who in turn will take this matter up with the division superintendent as it is imperative that anyone cutting out a brake for any reason whatever should apply an air brake defect card properly filled out as to the defect for which it was cut out.

Hot Boxes on Incoming Trains

As a general rule, car equipment coming in on time freights, or otherwise, having hot boxes, should be given immediate attention to avoid the entire destruction of the packing, dust guards and journal, due to continued burning of the waste. Under these circumstances, the packing should be removed immediately when discovered and the journal jacked up and allowed to cool so that the work can be done on the train while the box is cooling off and inspectors return and finish the job without having to switch cars out. It very often happens that cars are marked out for cut journals under these circumstances, when this is not a fact, and a large saving in expense can be obtained through diligent following up of the work along the lines described. All packing when pulled out should be placed in a suitable pail or metal receptacle and not thrown on the ground.

Method of Treating Hot Boxes En Route

In stating the method of treating hot boxes enroute, for the information of train crews, the following should be remembered: As prepared packing and tools are assigned as a part of the train equipment, they should consist of a standard bucket, packing iron and hook. Trainmen should see that the packing is protected from dirt and water.

It should be the duty of the trainmen when taking cars at points where there are no car inspectors to examine the

journal boxes and see that they are in proper condition for safe movement. A little time and attention may save the annoyance of a hot box and serious detention to the train.

When there is evidence of a journal heating, open the box lid, insert the packing hook along the journal to ascertain if the packing is in contact with the journal for its entire length and that the journal is not cut. If the packing is not in contact with the journal and the journal is not cut, add fresh packing, if necessary, or raise the packing in the box, so that it may have proper contact with the journal. If it continues to heat, a new brass should be applied.

In applying a new brass, first remove the packing from the box, placing it in a bucket, or in some other manner protecting it so that it will not come in contact with the ground; then jack up the box. Frequently, when jacking up the box, the wheels will rise from the rail, holding the brass and wedge against the crown of the box. A block placed from the top of the wheel to the sill of the car will prevent this. When the brass and wedge are free from weight, insert the packing tool along each side of the brass and pull the brass and wedge forward out of the box; this to keep the brass from turning to the underside of the journal and dropping to the bottom of the box. Packing removed from the journal and not used in the repacking of the box should be returned to the point designated by official order on the respective divisions.

When water is used for cooling, the journal should not be cooled to a low temperature and water should not be used until the brass has been renewed. Notice should be given at the end of the run at the point of cut-out, if the car is cut-out, that the journal has been cooled by water, in order that it may be removed at the first opportunity.

Carefully examine the journal with the packing hook to determine rough or cut places. The condition of the journal should be mentioned on the report of hot boxes. Before applying a brass, place the wedge on it and note that the wedge rests on the crown of the brass with some clearance on the sides.

To determine the fit of a journal, cover the surface of the brass with a thin coating of oil, which should be squeezed from the packing, and place the brass on the journal, moving it back and forth a few times. Then remove it carefully and if the face shows that it bears on the edges of the brass, the brass is too small in radius, which would cause it to heat. If the brass bears along the crown for its whole length and from $1\frac{1}{2}$ to 2 in. in width and clear of contact at the edges, it is of proper size. The face of the brass should be oiled before applying, by squeezing oil from the packing.

Apply the wedge on top of the brass after the brass has been placed on the journal and be sure that the wedge is back in proper position and not resting on the lugs which hold it in position in the crown of the journal box. In lowering the journal box, be sure that the wedge and brass are properly seated.

If the car having a hot box is set off at a siding, or brought into a terminal, the box should be plainly marked by the trainmen in the absence of an inspector. This mark must remain thereon until removed by the car inspector or repairer after the box has been properly cared for. A box thus marked will indicate to the car inspector or repairer that it has given trouble on account of heating and requires attention.

LIGNITE BRIQUETTES, manufactured from natural coal tar and lignite from Alberta, Canada, coal mines, will probably be placed on the market before another year. Government experts are working on a solution to extract tar from the extensive sands of Alberta, with a view to using it in the manufacture of briquettes.—*The Engineer, London.*

EXPERIMENTS WITH LATHE TURNING TOOLS

In a paper recently presented before the Institution of Mechanical Engineers George W. Burley described a series of experiments covering certain points relating to the cutting qualities and efficiency of lathe turning tools made in the machine tool laboratory of the University of Sheffield. As a result of these experiments the following conclusions were reached:

1. There is no practical cutting speed below which it is impossible to obtain a satisfactory surface on plain carbon steels by means of ordinary lathe finishing tools, whether these be made of plain carbon tool steel, ordinary (non-vanadium) high speed steel, or superior (vanadium) high speed steel. There is, however, a maximum limiting speed above which a satisfactory finish cannot be obtained on account of the tendency of the tool to pluck at and tear the surface, this tendency being related to the phenomenon of building up on the cutting edge of the tool. For the finishing of mild steel this limit is not very different for each of the above three varieties of tool steel and is within the range of 48 to 58 ft. per minute. For the finishing of hard steel this limit does depend somewhat on the variety of tool steel which is employed and is within the ranges of 23 to 28, 17 to 21, and 28 to 34 ft. per minute for the three varieties of tool steel respectively.

2. The durability or life of a lathe finishing tool, whether of plain carbon or high speed steel, is for all cutting speeds below the limiting speed some function of the reciprocal of the cutting speed; in other words, an increase in the cutting speed below the limiting value is always accompanied by a decrease in the life or durability of the tool.

3. The most suitable angle of side rake (that is, the angle of side rake associated with maximum durability and cutting power) for a high speed lathe roughing tool working on steel depends upon the physical properties of the steel. For mild steel turning it lies between 20 deg. and 25 deg., while for hard steel turning it is of the order of 10 deg.; and if these angles are either increased or reduced there is always a depreciation of cutting power.

4. The color of the turnings formed by a high speed lathe roughing tool when working on steel is not necessarily a true index of the condition of maximum cutting efficiency. Thus, in the case of hard steel turning, the turning color which is associated with maximum cutting efficiency is a pale blue, while a mild steel turning which is removed under the conditions of maximum efficiency is practically uncolored, apart, of course, from the natural gray color of the steel.

5. The net power consumption of a high speed roughing tool is dependent, other conditions being constant, upon the amount of top rake on the tool, the relation between these two quantities being reciprocal in character, so that, within the limits of ordinary practice, a reduction in the top rake

angles of a tool is always accompanied by an increase in the net amount of power consumed. The law connecting the variations of the two quantities appears to be of the nature of a straight line law for all qualities of steel machined. There are, therefore, no critical values of the rake angles in regard to power consumption as there are in regard to durability and cutting power.

6. The cutting power of a high speed lathe tool is influenced by both the cross sectional area of the shank of the tool and the nose radius, but the influence of the latter factor very largely predominates in all cases. Thus, with a number of different sections of tool steel, an increase of the nose radius of 100 per cent produced an average increase in the cutting power of 45 per cent; whereas an increase of the cross section of the shank of the tool of 500 per cent with a constant nose radius produced an average increase in the cutting power of only 8.5 per cent.

7. The effect of raising a roughing tool so that its cutting edge is slightly above the horizontal plane passing through the lathe centers is, generally, to increase the cutting power of the tool slightly and to reduce its net power consumption slightly, when compared with its normal position, that is, with its cutting edge at the same height as the lathe center axis.

8. Forging the nose of a lathe cutting tool does not materially affect its cutting power and durability, there being practically nothing to choose between a completely ground tool and a forged and ground tool, otherwise identical.

9. The general direction and the active length of the cutting edge of a high speed tool have a slight influence upon the net power consumption of the tool, the influence being such that, with any given depth of cut, if the active length of the cutting edge is increased by an alteration of the general direction of the edge, the net power consumed is increased under conditions of working otherwise identical.

10. There is no marked difference in the net amounts of energy required per cubic inch of material removed from mild steel and hard steel bars at high and low cutting speeds.

11. The increase in the cutting power of a high speed roughing tool resulting from the use of a given stream of water as a cooling agent is greater with small cuts than with heavier ones, indicating that, with heavier cuts, heavier flows of coolant should be used. The velocity of flow of a stream of coolant does not very materially affect the improvement in the cutting power of a tool due to the use of the coolant, provided that the velocity is not such as to cause excessive splashing of the coolant.

12. The cutting efficiency of a high speed roughing tool depends very largely upon the condition of the cutting edge of the tool; and although a tool with its cutting edge blunted in the cutting process may continue to cut, it cannot be used in that condition for the purpose of starting a new cut.

Erecting Shop, Nevers, France

MECHANICAL TRADES SCHOOLS OF THE A. E. F.

Short Intensive Training in the Mechanical Trades
Organized in France After Signing of the Armistice

BY MAJOR C. E. LESTER

THE experience of our army in the late war in Europe taught that in modern wars the need for men well trained in industrial service is as great as the need of men trained in combat service. In putting into the field an army of a million men the service of supply is the all-important factor in the army's success, and in this service there is need of men well trained in almost every mechanical trade to keep the service functioning properly. These facts were forcibly demonstrated in more than one instance and were the prime reasons for establishing schools of various kinds in the army both in France and in this country.

The steady and enormous demand for skilled men of all crafts and professions was never entirely met prior to the armistice and gave emphasis to the fact that our peace-time army, to be self-sustaining to any degree, should be given training in production as well as destruction and that serious consideration should be given to the establishment of schools in the service where not only engineer and air service troops but all combat troops, as part of their curriculum, would be given training in the various mechanical trades.

The mechanical trades schools of the intermediate section of the service of supply constituted a unique departure from all educational projects and have occupied an altogether distinct place in the training section of the army. They form such an unusual part of the vast educational program of the A. E. F., and are so unlike anything hitherto attempted in American education, that they may reasonably be expected to have an important bearing on the possible vocational training for the peace-time army.

In the combat divisions and wherever troops could be spared after the armistice, educational courses from local studies at the Y. M. C. A.'s and post schools to scholarships in French universities were provided. In surveying the possibilities of extending the plan, the educational commission developed the fact that in the intermediate section of the service of supply there were vast manufacturing and repair plants that might in some way be utilized for the education

of several thousand men in the mechanical trades who, soon to be returned to civilian pursuits, could be assisted in more thoroughly fitting themselves for a peace-time occupation and who wished increased rather than lessened earning capacity as a result of their tour in the service.

Origin of Mechanical Trade Schools Plan

The following extract from the report made by Carlton Gibson of the educational commission and later director of mechanical trade schools of the intermediate section, will perhaps give the best exposition of the plan for utilizing the Nevers locomotive and car shops as a means of affording special mechanical training to 500 men from the combat divisions: "Credit is due to the general superintendent of the 19th Grand Division Transportation Corps for the scheme of utilizing the large railroad shops at Nevers, perhaps the most attractive and best equipped shops in all Europe, for training men in all trades related to railroad transportation, a very important branch of the service. The installation in these shops of all the best types of modern machinery gave to him the vision of tying the production work of the shop with the training of several hundred men selected from the armies, in machine shop practice, foundry work, oxy-acetylene welding, blacksmithing, pattern making and other mechanical trades.

As a result of this report the following schools were decided on and established within a period of three weeks:

- Nevers—Railroad Shop.
- Verneuil and Romarantin—Motor Reconstruction Park.
- Gievres—Signal Corps Shops.
- Mehun—Ordnance Shops.
- Decise—Driver Mechanics School.
- Souzy—Remount School and training in the various occupations of the plants.

The need for additional highly skilled men in Nevers shop had been a problem since its inception and my desires to understand our good mechanics with earnest boys and men who desired to further their mechanical knowledge could not be wholly gratified due to scarcity of men particularly of de-

pendable men. I saw in the desire to give men of combat troops mechanical training an opportunity to augment my forces and increase production provided that we were not hampered by the interference of dictatorial officers who were unfamiliar with shop work, or annoyed by the commanding officers of men detached to our schools.

Unusual Conditions to Contend With

It was felt that could we be allowed to operate as before and handle the schools as we desired the students could be put on a productive basis, giving them the benefit of our best efforts in expert supervision and instruction and working with our most skilled men and in a few weeks' time increase production sufficiently to compensate, or nearly so, for the additional man hours expended. It was never felt that the signing of the armistice lessened our responsibilities and the maximum output obtainable was the figure for which we were striving. How well we succeeded is another story, however, I may say, that our output increased steadily in proportion to the hours expended from the armistice till cessation of operations in May, 1919. My one thought was to so co-ordinate the school and shop that the students would receive an intensive, intelligent and instructive course of training and we would get value received in a fair day's work each day.

It may not be inappropriate to say that while the schools were authorized by General Headquarters and sponsored by the educational commission and literature issued showing the advantages of the schools and inviting soldiers of the regular establishment to take up courses and ordering to the schools such as desired to go, the burden of developing the complete courses of study and work, the organizing of provisional companies, the problems of housing, feeding, clothing, and general welfare, the problems of assimilation, the selection of instructor personnel (technical and practical) fell to the superintendent of shops.

No outside assistance other than colored cooks and the administrative officers for the provisional companies was received and all duties other than these were detailed to officers of our organization in addition to their other duties. Provisional companies No. 1 and No. 2 were organized and selections from the student personnel were made to carry on the routine military duties, such as first sergeant, company clerk, platoon leaders, squad leaders, and fatigue. This work was required to be done in addition to the duties in the shop. The companies did no guard duty and no fatigue other than company but were required to stand reveille and participate in the daily short period military drill and regimental parade at retreat. This practice was inaugurated in February, 1919, for all shop men by reducing the shop hours to 8 and using one hour for drill and ceremony. This broke the monotony of the daily shop grind and assisted in keeping the men physically fit and mentally alert and gave to them the snap and set up common to veteran combat troops but seldom found in other branches of the service.

How the Work Was Organized

Immediately on obtaining information that the schools were to be established, time was taken by the forelock and a vocational officer was appointed to whose ability is due a great share of the credit for the successful operation of the schools. This officer was ably assisted by specially selected men that formed the body of the schools' instruction force. Text books were not available but we had the engineer corps field technical library as a basis to work on and developed courses of study for the several occupations before the arrival of the students. As developed, the courses were not elaborate, but included the fundamental facts and theories consistent with the trade concerned.

About the time that the schools were started it was learned that the 3 months' training period, as first planned, would

of necessity be shortened by the plans to discontinue all operations not later than July 1, 1919. The scheme for utilizing one day for class room work was changed to give each student but $\frac{1}{2}$ day weekly and the only subjects to be taught were shop arithmetic and applied practical mechanics. The former was a practical course in elementary mathematics with numerous applications to shop problems; the latter was intended to acquaint the student with the fundamental facts and theories of the science of mechanics which underlie all shop operations.

A course in elementary mechanical drawing was given to such students as were desirous of becoming draftsmen or those who desired to acquire a working knowledge of mechanical drawing. In addition to the practical shop work a series of lectures was arranged; these lectures to be given by various shop

Administration Building and Entrance to Shops

officers on subjects of interest to the students in various courses. This schedule was somewhat interfered with by ordering to the U. S. many of the officers concerned.

In view of the shortening of the schedule as originally planned it was felt that class room work and theory would have to be sacrificed for practical work to enable the student to have sufficient knowledge of shop practices to fit him for a position after his return to the U. S. A. and his discharge from the service.

The men enrolled in the school were from all branches of service in the A. E. F. the majority being from combat divisions. The following fighting divisions were represented: 1st, 2nd, 3d, 4th, 5th, 6th, 7th, 8th, 79th, 81st, 88th and 3d army headquarters.

Selection of the Student Personnel

As the men reported they were interviewed by the vocational training officer who obtained in addition to such information relative to the man as could be judged by a personal interview, the man's age, schooling, civil and army occupation and his preference in regard to proposed training. This information was recorded on a form and used in assigning students to their duties. In establishing of the schools it was felt that those who would desire to become students would be men somewhat above the ordinary caliber and that they could be put upon an honor basis and the schools run as a college. Prior to the opening of the schools all arrivals were addressed by the commanding officer on the subject of the proposed method of running the school and the duties of the officers in charge, the co-operation expected from the workmen and the duties of the student body. Prior to this all members of the old organization had been called upon to exercise every effort and sacrifice their own desires in order to assist those who apparently needed and wanted help.

It developed, however, that there were many reasons other than study and development that brought some of the students (so called) to the schools. Some thought that by getting into

the S. O. S. that their chances of returning home quickly were enhanced, some did not want to go into Germany with their outfit and others who expected they could get out of a few week's work. The honor system did not work out with such men and they were put on a strictly military basis. In justice to the student body as a whole they were men of good character and came with the fixed purpose of improving themselves.

The splendid equipment of the shops offered unusual opportunities for practical work in the metal trades and each department was headed by men of experience, well qualified as instructors. Due to many outfits being ordered home shortly prior to the opening of the schools April 1, 1919, many men were deprived of the opportunity of attending and but 267 actually reported.

The students were assigned as follows:

Machine shop practice.....	82
Erecting Shop (Loco.).....	48
Car repairing, wood working, pattern making.....	39
Sheet metal and pipe fitting.....	26
Electrical work.....	23
Foundry practice (Brass and iron).....	19
Tool making and die sinking.....	10
Blacksmithing.....	13
Boiler Making.....	12
Autogenous and electric welding.....	5

Of the 82 men assigned to machine shop it was found that nearly 75 per cent had some previous experience such as running a drill press or working one particular kind of machine, and they desired to broaden their knowledge. Our machine shop was without question the most modern locomotive machine shop in the world. Every machine was the very last word in its kind, each having individual motor drive and of the latest model. The work in this department and tool room along the same lines was especially attractive to the students, more so than in any other department. Every effort was made to give the student the widest experience possible, which was considerable in a shop of this character.

Valuable Results Accomplished by School

The erecting shop offered many opportunities to the ambitious student to gather knowledge of the erection of locomotives of many designs. Locomotives built by the American and Baldwin locomotive works were assembled at Nevers as well as many types of Belgian, all types of French passenger locomotives, trench locomotives, "Economique" locomotives,

Erecting Locomotive Cranes

metre gage and German freight engines. Here one could by observation learn many things that it would be difficult to learn elsewhere. The car shop offered opportunities to men who had no previous training to pick up a trade (today rather lucrative) in a short time. This vocation is quickly and easily mastered.

Practically all the foundry practice students were men who had some previous experience and grasped this opportunity to put themselves in readiness to accept a journey-

man's job on discharge from the service. The same may be said of a large share of students in the sheet metal department.

The smith shop students were nearly all men who had been horse shoers or country blacksmiths and they all made enthusiastic students in the heavier railroad work with the steam hammers to assist. After the course was under way a card index system was developed to keep records of work done and the students' individual rating. The different department foremen and instructors were required to submit a weekly progress and rating sheet from which, with class room work included, the student's weekly rating was determined. Due to cessation of activities in the shops the schools were drawn to a close May 31, 1919, each student being furnished a certificate of studentship and forwarded to his organization or sent to an embarkation camp for return to this country.

The only regrettable thing in connection with our efforts was that the schools could not have a longer period of existence. Without doubt the men who took advantage of their opportunities of the mechanical trade schools of Nevers gained some valuable knowledge and experience to assist them in civil life that might have been doubly valuable with another few weeks' training.

SEPARATOR FOR COMPRESSED AIR LINE

In connection with the care and use of pneumatic tools the use of a separator to extract the oil and water from long pipe lines conveying compressed air is highly desirable. Some of the undesirable effects of oil and water accumulating in such lines were pointed out by H. S. Covey, secretary of the Cleveland Pneumatic Tool Company, in an address before the Railway Club of Pittsburgh, an abstract of which was printed

Sectional View of Oil Separator

in the *Railway Mechanical Engineer* of May, 1920, page 292.

The accompanying sketch shows a sectional view of the oil and water separator referred to by Mr. Covey in his address, as follows:

The separator consists of a 3-ft. section of 5-in. iron pipe, capped at top and bottom, and is attached to the branch air pipe lines which feed the drop pipes and hose lines. The air leaves the separator at the top, entering the branch outlet pipe attached to the cap at the opposite side to the inlet. The air is thus freed from oil and such water as may still remain in the system. The separator is drained of its accumulated water and oil through the drain cock provided at the bottom cap of the separator. Occasionally the lower cap of the separator should be removed and the baffle plates cleaned by means of a stream of compressed air which quickly removes the oil adhering to them.

INTERESTING SHOP EMPLOYEES IN SHOP OUTPUT

Simple Scheme of Displaying a Comparison of Man-Hour Production for Information of the Men

ONE of the most marked effects of the Railroad Administration operation of the railroads is the changed conditions which it has brought about in railroad shops. Piece work, which had very extensively been employed in car shops and to a considerable extent in locomotive shops, was abolished, rates of pay re-adjusted, helpers advanced to mechanics and many shops formerly working under non-union

seriously, in almost every railroad shop of importance in the country.

The changed conditions have required new measures on the part of the managements to bring production back to reasonably satisfactory standards. At one shop where, during the latter part of last year, a marked falling off in the man-hour output was being experienced an ingenious means of present-

Form of Board on Which Comparative Output Figures May Be Bulletinized for the Inspection of the Men in the Shops

conditions, although now nominally open shops, have become practically 100 per cent unionized. In such shops the organization and operation of grievance committees has been an innovation to which both men and shop managements have had to adjust themselves. The result of all these changes has been a disturbance which has affected output, more or less

ing a comparison of output by months of the current and preceding years in a form which could readily be comprehended by the men in the shop, was developed and employed with gratifying results.

The plan had its inception in a conference between the local shop committee, the shop officers and the superintendent

of motive power, at which the facts of the situation were laid before the committee. When confronted with a statement that the shop had actually suffered a decline in output the members of the committee were loath to believe that the situation was as represented. An inspection of the records of men employed, hours worked and locomotives turned out, however, convinced the committee, one of whom expressed the opinion that, if they knew them, no one would regret these facts more than the men in the shops and that if a means were available for laying before the men the month to month facts as to output they would remedy the situation themselves.

As the result of this conference the scheme here described for calculating and recording the month to month output on a comparative basis was developed.

In order that a reasonably satisfactory comparison of output might be made some method of weighting the various classes of repairs was necessary. This was worked out on a so-called point basis, each class of repairs being assigned a number of points such that the numbers assigned to the different classes of repairs would bear a relationship to each other approximating the relationship between the actual man-hours of labor required on the average locomotive going through the shop for the different classes. The following number of points have been assigned to the various classes of repairs:

Class 1 rebuild (new).....	100
Class 2 rebuild	90
Class 3 rebuild	80
Class 3 general	70
Class 4 heavy	60
Class 5 heavy	50
Heavy	40
Light	30
Specific	20

This classification is posted at the top of the output meter board which is placed in the shop where it is accessible for the inspection of the men.

In order to eliminate the effect of possible variations in conditions from month to month, the comparison is made between each month of the current year and the same month of the preceding year. The comparison is expressed as a per cent loss or gain, as the case may be. A simple formula has been worked out for the calculation of this per cent and a blueprint copy of the formula is posted near the output meter board in order that the basis of comparison may be generally understood. The first step in the calculations is the determination of the aggregate number of points equivalent to the output for the month. With a knowledge of the number of locomotives in for each class of repairs which was turned out during the month, this is readily determined by referring to the percentage or point basis just described. The next step is the determination of the total man-hours worked, which is the number of shop hours for the month multiplied by the number of men employed. The basis of comparison is then arrived at by dividing the total number of man-hours worked by the number of points, giving the number of man-hours which were required to produce one point. The proportion of increase or decrease of this figure for the current month is the measure respectively of the loss or gain of output per man-hour. This is entered in the proper percentage column.

Reference to the drawing will show the method of posting the information. It will be seen that the middle portion of the board is divided into three sections and each section in turn is divided into two parts, one devoted to the current month and the other to the same month of the preceding year. Each part is provided with a column for each week of the month, in which the number of locomotives receiving each main class of repairs which was turned out of the shop during the week is entered in the first section, and the percentage of gain or loss entered in the proper part of the second section.

In the third section is shown the number of men employed and the number of working hours per week for the current month and the same month of the preceding year. As shown on the drawing, the column captions of this section of the board are lettered on a removable strip of sheet metal which is pulled out of the slide at the end of each month and replaced with one lettered for the next month. In entering the figures in this section, white chalk is used for those for the current month and red chalk for those for the preceding year. The permanent figures in the lower section of the board are painted in the same colors.

The lower section of the board is devoted to a similar record by months, a complete record of the calendar year being entered here month by month.

The scheme is simple to operate and is readily understood by the men. Its value is indicated by the results shown for the first three months of the current year. That the men have taken an interest in the success of the shop is clearly indicated by the marked improvement in output which has been obtained since January and the significant fact in connection with these figures is that the improvement has been effected almost entirely by the men themselves. With the facts as to conditions clearly before them, no other measures have been necessary to bring the output back to and even to exceed that of the same period of the preceding year.

SAFETY PLATFORM FOR THE ERECTING SHOP

The cab of a locomotive, after the engine has been cut off from the tender and placed in the erecting shop, is rather a dangerous place to work and casualties are frequently caused by men stepping off the apron and falling into the pit. In order to remove this element of danger the platform shown in the drawing has been developed and used successfully for some time in the Battle Creek, Mich., shops of the

Platform for Use Back of Locomotive Cabs in the Erecting Shop

Grand Trunk, Western Lines. The frame is built up of pipe and cross pieces of 7/8-in. material, which are welded to the pipe. At the base of the frame is 9 ft. 6 in. long and spans the working pit, the height of the platform being 5 ft. above the level of the shop floor. The platform is covered with standard smokebox netting and a pipe rail 19 in. high is placed across one side.

The platform is placed across the pit just back of the locomotive, the front side extending under the back edge of the apron. It thus increases the working space in the cab and provides a safety rail which is an effective protection to the men. The cross pieces between the two frames also facilitate climbing in and out of the cab.

NICKEL PLATE POWER PLANT AT CONNEAUT

Results of a Successful Superheater Installation in the Stationary Boilers at Conneaut, Ohio

BY J. S. MORRIS

Assistant Engineer, N. Y. C. & St. L.

DURING the past few years, the traffic handled by the Nickel Plate has gradually increased, with the result that the shops and engine houses have had to increase their output considerably. This, of course, caused the load on the boiler plants to increase to such an extent that during the winter months the boilers had to work under a heavy overload. The conditions at Conneaut reached a point where it was necessary either to purchase additional boilers or to increase the output of the boilers then in use. At this time it was suggested that superheaters would solve the difficulty.

Assuming that the use of superheated steam would increase the capacity of the power plant 15 per cent, the cost of the superheater installation would be approximately two-thirds the cost of installing another horizontal return tubular boiler of a size sufficient to give the same increase in capacity. Not only would the first cost of the superheaters be less but it was thought that they would show an annual fuel saving of at least 10 per cent with the same load, which would not only pay the charges against the investment, but would leave a substantial margin of profit besides. If an additional boiler was installed, the fuel consumption would

The engine room, which is located adjacent to the boiler house, contains the following machinery: one 100 H.P. high speed Buckeye engine with piston valves, direct connected to a 75 K.W. direct current General Electric Co. generator which supplies electric power for all of the motor-driven machinery and electric lights for the entire shop; also one 1,050 cubic foot Ingersoll-Rand air compressor with slide valves on the steam cylinders and a 150 H.P. simple Corliss engine which drives all the belt-driven tools in the machine-shop.

The boilers also supply steam for a 75 H.P. Erie City slide valve engine located in the wood mill, about 400 ft. from the boiler house. In the blacksmith shop they have one 1,200-pound steam hammer and one 2,000-pound hammer. A twenty-eight stall engine house located about 600 ft. from the power plant uses steam to blow up engines, and also to operate the engine house. Steam is conveyed to the engine house by means of a four-inch underground steam line. This line is carefully insulated against heat losses and offers several important advantages over the more common type of overhead steam line.

Superheater Header Installed at Conneaut

probably increase, especially at times when the plant was not working under full load.

Description of Power Plant

The boiler house now in use was built in 1913 and contains three 180 H.P. horizontal return tubular boilers, built by the Bass Foundry & Machine Co., and two 70 H.P. Erie City boilers of the same type. All of the boilers are hand fired and use run-of-mine bituminous coal with an average heat value of 12,500 B.t.u. per pound. Each of the three 180 H.P. boilers has 35-inch steel smoke stacks 100 ft. high and the two small boilers have 28-inch stacks the same height.

Description of Superheaters

During the month of September, 1919, superheaters were installed in each of the three 180 H.P. return tubular boilers. The superheaters were designed and installed by the Locomotive Superheater Co. The superheater header is hung horizontally just back of the boiler, with the ends resting on the side walls. The header is constructed of steel and is in two sections; one section for saturated steam and the other for superheated steam. The units, which are made of 1½-inch cold drawn seamless steel tubing, hang vertically from the header in the space between the rear of the boiler and the back wall.

The ball joint on each unit is forged integral with the tube and is clamped to the headers by means of a specially designed forged steel clamp, similar to the arrangement used on locomotive superheaters. The units are arranged in one loop per unit and each boiler has sixteen units with a total of 104 sq. ft. of heating surface.

Superheater Header and Units in Place

Superheaters were not installed in the two 70 H.P. boilers; and in order to separate the superheated and saturated steam, these two boilers were disconnected from the main header and connected directly to the engine house line. A by-pass line was installed between the main header and the engine house line so that the two small boilers need only be used during periods of the year when the three 180 H.P. will not carry the entire load.

the other two tests were made at night with the different engines loaded by artificial means. This load was maintained constant for four hours.

About three weeks after the superheaters were installed, three similar tests were conducted and as far as possible conditions of the original tests were duplicated.

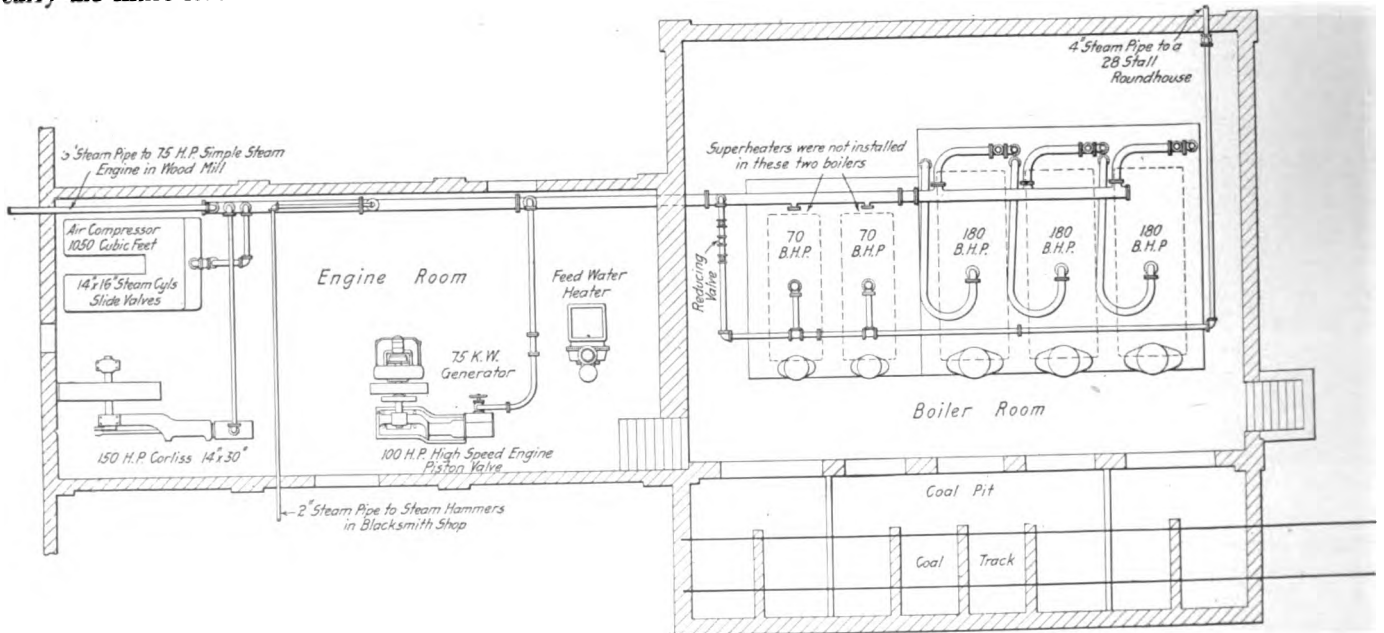

All the coal consumed by each boiler was accurately measured by weighing on platform scales. The feed water was measured by means of a recording water meter which was accurately calibrated before and after each set of tests, and was located between the feed pump and boilers. The average indicated horsepower of the Corliss and wood mill engines was secured by indicator cards taken every five minutes. Switchboard readings were taken at the same intervals. A proximate analysis and heat value of the coal was secured from samples taken during each test.

The two tests shown in Table I were made from 8 a. m.

TABLE I—RESULTS OF EIGHT-HOUR TESTS WITH BOILERS CARRYING SHOP LOAD ONLY

	Saturated steam	Superheated steam	Per cent increase	Per cent decrease

to 4 p. m. with the regular machine shop load on the three 180 H.P. boilers. During these two tests the engine house load was carried on another set of boilers. The two tests shown in Table II were made at night with each engine run-

Outline of the Power Plant at Conneaut

Results of Tests

From three to six weeks before the superheaters were installed four complete power plant tests were conducted. Two of these were of eight hours' duration with the power plant carrying the regular shop load from 8 a. m. to 4 p. m. and

ning under a constant load for four hours, with blacksmith shop and engine house lines cut off.

Practical Results Obtained

The following table shows the number of tons of coal consumed by this plant during the past three winters, with satu-

rated steam used during 1917-18 and 1918-19 and superheated steam during 1919-20:

TONS OF COAL CONSUMED PER MONTH			
	1917-18	1918-19	1919-20
October	838	1,087	797
November	952	885	877
December	1,314	1,174	1,080
January	1,371	1,174	1,340
February	1,125	1,062	1,116
March	1,311	1,105	1,066
Total	6,911	6,487	6,276

It is apparent that a very material saving in fuel has been effected by the superheaters. A comparison of the past winter with the winter of 1918 and 1919 is not entirely fair as the past winter was very severe and long and the fuel obtainable was of poor and very irregular quality, while the winter of 1918-19 was mild throughout and the fuel obtainable was the best. Even under these conditions the superheaters show a considerable reduction in the amount of coal consumed.

A comparison with the winter of 1917 and 1918 is more nearly fair, as the weather and fuel conditions were about

The Boiler House at Conneaut

the same as during the past winter, and in this case the superheaters show a very marked reduction in the amount of coal consumed.

Fuel economy is not the only benefit that has been obtained from the installation of these superheaters. A very important result has been the improved operation and output of the different steam engines, steam hammers, air compressors and blower lines. No figures are available showing the actual savings due to this cause, but experience has demonstrated that the improvement has been considerable. Especially was this noticeable in the wood mill engine, which is located about 400 feet from the boilers. Before the use of superheated steam, this engine was badly handicapped during the winter months, due to the large amount of condensation in the three-inch overhead steam line, with the result that it was unable to keep the wood mill machinery operating up to the speed at all times. Since the superheaters were installed this trouble has been entirely eliminated

and the engine has sufficient power to easily handle the wood mill load.

The same condition existed but to a less extent in connection with the engines and in the main power plant, as there has been a decrease in the condensation and friction losses in the four-inch underground steam line. From several tests it was found that the pressure available at the engine house was from five to ten pounds higher with superheated steam than with saturated.

At the time the superheaters were installed there was some question whether the slide valves on the air compressor would operate successfully with superheated steam. About two months after the installation the valve chest covers were re-

moved and it was found that the valve seats were in good condition and have caused no trouble since. Except for the installation of additional valves, together with the changes in connections incidental to the superheaters, the power house steam lines have not required any rebuilding and are giving satisfactory service. Shortly after the installation, two or three of the old flange gaskets in the main header blew out and had to be replaced. On one or two occasions it has been necessary to tighten up the units, which proved a simple matter, as all these bolts are accessible from outside the boiler setting.

BURNING EASTERN COALS ON CONVEYOR FEED TYPE STOKER.—Difficulty has been experienced in burning eastern bituminous coals on chain grate stokers, due to the fact that they cake under the arch, preventing the entrance of air through the fuel bed and checking combustion. In a paper presented before the American Society of Mechanical Engineers, Lloyd R. Stowe described a stoker developed by the Laclede-Christie Clay Products Company, which it is claimed may be used satisfactorily with eastern bituminous fuels. The stoker is of the conveyor feed type and operates with mechanical draft. High ignition temperatures are employed. The air supply is graduated from the feeding end to the discharge end and the fire is thickened at the point of ash discharge. These features are said to result in the prevention of caking, the assurance of a CO₂ content of from 10 to 12 per cent and intimate mixture of air with the combustible gas. Rates of burning up to 60 lb. per square foot of grate area per hour are obtained as compared with 25 to 35 lb. on chain grates. The percentage of combustible in the ash is reduced 50 per cent.

GOVERNMENT OPERATION has left the country with an insufficient number of cars and locomotives, and with an unusual proportion of the existing equipment out of order. There is to be a shortage of cars for a long time to come. It is well to know where responsibility for it chiefly lies. But the really important thing just now is to look ahead and make arrangements for the most efficient use of such cars as the country has in working order.—*Boston Transcript*.

Looking Down the Erecting Bay in Silvis Shop

REDUCING THE COST OF LOCOMOTIVE REPAIRS*

Use Modern Tools and Scheduling System; Keep Men at Their Jobs; Avoid Unnecessary Finish

BY S. W. MULLINIX

Superintendent Shops, C. R. I. & P., Silvis, Ill.

REDUCING the cost of repairing and maintaining locomotives has been open for discussion ever since railroads have been in existence and is one of the most important questions which confronts the mechanical department today; one which can only be solved by careful study and efficient handling, plus good, hard, honest labor.

In order to be brief, and to cover the subject as thoroughly as possible, I will divide the cost between labor and material, treating each one separately.

Labor

Never before has labor in all its branches required the efficient handling that it does today, and in view of the enormous increase in the cost of labor, we must find methods of increasing the production of every employee.

Make use of all existing labor saving devices, such as electric and oxy-acetylene welders, high speed tools, drills and cutters, air tools, electric trucks, cranes and hoists. Create wherever possible new labor saving devices, or better methods of doing the work. Purchase where possible modern machines to replace obsolete machines found in a great many railroad shops today. While a great many modern machines and tools have been installed, we have not kept pace with other manufacturing industries in the purchase of tools and machinery to handle repairs to the present locomotives. Establish and maintain rigid standards on as many parts as possible that they may be manufactured in quantities on machines especially adapted for the purpose. This alone will save many dollars in labor in small shops and roundhouses that are forced to furnish parts they have not the facilities to make, which might just as well have been manufactured in larger shops, or better still, in a separate manufacturing plant.

Rearranging and Regrouping Machines

The rearranging and regrouping of machines to eliminate the handling of material from one part of the shop to

another often produces great savings. I recall one case where machines were rearranged for repairing driving boxes. From the time the driving box was placed on the floor to be overhauled complete with crown brass turned, shaped and pressed into box, gibs and lateral face applied, drilled, plugged and planed, the cellar fitted and the box bored ready to apply on the journal, it traveled just seventy-two feet, and part of this distance was from one hoist to another.

In another case on the repairing of flues, from the time the flue was started on the first machine, after it had been rattled until it was completed, safe end applied, cut to length, tested and annealed, it traveled just sixty feet, with no back hauls whatever.

Dividing Shops Into Separate Departments

When large enough, divide shops into small departments, such as rod and link, wheel, air, etc., giving each, machine and equipment enough to perform its own work without depending on some other department. Have some one responsible for the performance of each department.

Cleaning and Stripping Engines

Engines and tanks should be thoroughly cleaned, all coal and cinders removed, and the boiler washed out before the engine is placed in the shop. Cleaning vats should be located as near as possible to the place where engines are being stripped and parts should be cleaned before being sent to the various parts of the shop to be repaired. All parts removed should be stenciled or tagged with the engine number so they may be replaced on the engines they were removed from. Many small pieces find their way to the scrap dock because they are not properly marked.

Do no more stripping than is absolutely necessary. We should be as careful in stripping an engine as we are in assembling it, for every piece removed must be replaced. We sometimes take down parts that were renewed or put in 100 per cent condition in some roundhouse only a few days before the engine was sent to the shop. Sometimes, in

*Paper presented at the Western Railway Club, on April 19.

order to get a few more miles out of the engine, after general repairs are authorized, steam pipe joints are ground and pipes reset. Piston or valves may have been renewed. In the event of any parts of the locomotive being in 100 per cent condition, the division people should so notify the shop. Care and good judgment should be exercised in stripping locomotives that come in for general repairs. A sledge and chisel bar in the hands of some one who does not know just what to remove, and how to remove it, can destroy in a few minutes that which will take much time and money to replace.

Engines should be carefully inspected before being placed in the shop, and also while being stripped, and parts such as pedestal binders, where found loose on the frame fit, should be marked the amount necessary to close before being removed, and should be repaired before being sent back to the engine.

Testing and Annealing Parts Removed

Parts removed, such as piston rods, valve stems, motion work, brake and spring rigging, crank pins and axles, and main and side rods after being cleaned should be carefully examined for cracks and flaws. Where possible they should be painted with a thin coat of good white-wash; this also applies to frames. After this has dried for some time, if there are any cracks or small checks, the oil or grease will work through the white-wash and can plainly be seen. It is also good policy to anneal as many of these parts as possible, as undetected flaws will show up while the pieces are hot.

Work Reports

An engine sent in from outside points should be accompanied by work reports, made out by the person having direct charge of the engine, as he knows the good and bad points of the engine under his charge, and is more competent to make out an intelligent report that will be of some use to the shop. The practice in many places of filling out the form furnished by the office, is to mark after each item "Repair" or "Examine," being sure to name all parts of the engine, so that if any defects are found after the engine has been repaired they can place responsibility on the shop making the repairs by referring to their work report.

Too much care cannot be taken in making out an accurate work report. All defective parts which have been giving trouble should be so reported, parts which have recently been repaired and are in good condition, such as air pump, crossheads, piston and valves, lubricators, injectors, and reversing gears, should be so reported, which will save the time and labor of removing and examining them.

Locomotives scheduled for the shop should be examined as far in advance of shopping as possible, to determine repair part requirements so that the store department will have plenty of time to meet the demand by placing orders for castings and other material not on hand. This examination should be supplemented by a more minute check while the locomotive is being stripped, at which time parts are more accessible. Care should be exercised to prevent the diverting to other uses of material intended for locomotives in the shop.

Every effort should be exercised to abolish the so-called "robbing system," a process used in reality as a substitute for material short in the store. Main shops of many railroads are called upon to furnish new and second hand material for shipment to outside points for ordinary as well as emergency use. Outside points are guilty of ordering such repair parts for emergency use in order to insure delivery when in reality there is plenty of time to manufacture and deliver. The removal of parts for such purpose from locomotives awaiting shop is expensive. Very frequently such parts as side and main rods, guides and cylinder heads that have been carefully refitted to the locomotives in the shop are removed and shipped.

Keeping Men at Their Work

Tool room and portable tools should be located in convenient places with respect to points where work is being performed to avoid unnecessary errands of mechanics and helpers.

Each employee should be given his assignment of work and to make it possible for him to perform it in a reasonable length of time, he should be given a fit place to work, proper tools to work with, supplied with working material, and, if necessary, instructed how to do it. This eliminates the need of men going from one department to another to get material and information. I recall one case which happened some time ago; the man operating the machine planing crossheads for guide fit, after getting the crosshead on the machine, would start out to find the size of the guide. Going first to the engine in the erecting shop, and not finding the guides, he would come back to the guide planer. If guides were not planed he and the man operating the machine would determine what size the guides would true up at, so he could go ahead and plane the crosshead to suit. This can be eliminated by having the foreman examine the guides while the engine is being stripped, and determine just what is needed and filling out a form made especially for the purpose, in two copies, which shows guides to be planed, the size to plane them to, or whether they are O. K. also giving the size. These forms should be sent to the guide and crosshead planer. In this way when the planer operator is ready to plane the crossheads, say for engine 2500, he takes the slip for this engine which shows right top guide planed to $7\frac{5}{8}$ in. or the right top guide O. K. $7\frac{5}{8}$ in, and so on for the other three guides, then planning the crosshead $1/32$ in. wider for clearance. This eliminated the necessity of either operator leaving his machine. It also enables the crosshead man to repair and plane the crossheads and deliver them to the erecting shop in many cases before the guides are planed.

The same applies to laying out shoes and wedges for driving box face. In most cases the men doing this work wait until the driving boxes are planed, making several trips back and forth to see when they will be finished. Most shoes and wedges are laid out to a 1-in. gauge. A good procedure for this work is as follows: As soon as the engine is blocked and binders refitted, shoes and wedges are put up and laid out, taking the size of the box from blue prints which we will call 14 in. Shoes and wedges are laid out for a 14-in. box, allowing for a 1-in. gauge and sent to the machine shop to be planed. Work on the spring rigging can then proceed and the engine be made ready to wheel when the foreman in charge of driving boxes has them finished. He calipers each of the boxes which are planed in pairs where possible. In all cases boxes should be bored central with shoe and wedge faces.

If the box, which according to the blue print should measure 14 in., calipers only $13\frac{1}{2}$ in., he makes out a slip, showing the right and left shoe and wedge to be planed to a $1\frac{1}{4}$ in. gauge, giving the slip to the men operating the shoe and wedge shapers. In cases where there is not enough stock to true up the size given they are planed $1/16$ in., $1/8$ in., or $3/16$ in. and liners applied to the inside. This should be done before shoes and wedges are sent back to the erecting shop. If possible a small drill press and bench should be located close to the shoe and wedge shapers.

On piston valve engines the gang foreman should examine the bushings and if out of round or worn hollow, he should fill out a form to be sent to the valve bench, which shows the engine number, whether the bushings are O. K. and giving the size, or whether they are to be bored and to what size they will bore out. A good practice is to bore valve bushings only twice, $1/8$ in. or $1/4$ in. over the original diameter. All rings and bull rings can be fitted to a bushing made for this purpose, and only in rare cases is it necessary

for men on the valve bench to go to the engine to fit rings. It also enables them to fit up their valves before the bushings have been renewed or rebored and makes it unnecessary for one department to wait on another.

The use of portable machines in the erecting shop for fitting frame and guide bolts, and for special pins and studs will save many trips from the machine to the erecting shop.

Roundhouses of any size should be equipped with enough machinery to handle their own work, especially their small work, as many hours of costly labor are consumed by mechanics and helpers going back and forth from the roundhouse to the back shop to get some small job done, which in itself interferes with the routine work in the back shop.

Routing and Scheduling

In all shops larger than the so-called one-man shop, there should be some method of routing engines and work through the shop, or a schedule system which will enable all departments to know just what work is to be finished first and when it is expected. Such a system enables the man in charge to tell just what departments are holding back the output. In nearly all shops the output is controlled by one department, and any steps that will tend to build up this weak department will increase the output. It is very essential that our forces be equalized.

No matter what the system, whether it be simple or elaborate, it will be of no use unless it is followed up and followed up religiously.

Supervisory Forces

One of the most important factors in increasing the efficiency of shops and roundhouses is the supervisory force. It is up to these men to make a careful study of their own particular class of work and department. They should be thoroughly familiar with locomotives and the tasks they have to perform and the conditions under which they have to perform them.

I believe a gang or boiler shop foreman should have some roundhouse experience, as only by actual experience do we realize what the roundhouse people have to contend with, and to know the things which give the most trouble. A machine-shop foreman should have some erecting shop experience; he should also be familiar with the so-called standard practice cards used in a great many shops to describe the manner of doing different classes of work. These foremen should be examined from time to time to make sure that they are familiar with all standard practices.

The staff meetings held once a month or oftener if possible, are very good if conducted with the spirit of making all feel that they are officers of the company and bringing them to realize the importance of doing their duties as such. We must increase our production without increasing the physical exertions on the part of the employees. I recall one instance which will give a good illustration. We used to saw cylinder packing rings by hand, which for two cuts required at least 15 minutes of hard labor. The rings are now cut in a special machine requiring only one blow with a light sledge and about two minutes' time.

The supervisory forces in large shops today are often compelled to use their judgment in doing certain pieces of work against that of the district or division mechanical people. An engine may have a cracked cylinder. The district or division people will in most cases recommend a new cylinder. The shop people after an examination may decide to weld it. In some cases we are unsuccessful, which results in our having to apply new ones, but there are many cases where the welded cylinders have given just as good service and have saved the company many dollars in labor and material. This applies to many other items besides cylinders.

The handling of men today to get the best results is a far greater task than it was years ago. What will work in one

case will not apply in another. It may be necessary to drive one man, beg the next and pray to another, but the course that will bring results is the one to use, and use continuously and eternally.

Suggestions from the Men

Many good suggestions will come from the rank and file if they are solicited in the proper spirit. Where we find a man trying to better conditions we should encourage him. It is not in our power to compensate him beyond his regular wage, but it is our duty to give him credit for the good things he does. It is surprising what good can be accomplished by patting a man on the back once in a while. In order to be efficient, men must be contented. This was shown very clearly during the period when the wage question was being settled.

If men are to be contented they must have good surroundings. The first impression a man has when he starts to work in a new place in all probability is a lasting one. If he is given a dirty locker, a broken monkey wrench and other tools not fit to work with, the chances are that, although he is a good man, he will be dissatisfied and will not remain with us. Men should have clean lockers and lavatories. If given good tools and a good drawer or box with a lock to keep them in, you will find that they will take care of them.

A man should be given his task to perform and if he is contented he will perform it.

Any job that is worth doing is worth doing right, and do not put off until tomorrow the things that should be done today, especially in a roundhouse. Although these things are as old as the hills, they are far more important today in reducing the cost on our locomotives than they were when they were written.

Visiting Other Shops

A great deal is accomplished by going to other shops to make observations and study the progressive features, whether they be large or small. We often run across kinks that are good and productive of reducing costs. A few years ago I had occasion to visit a large locomotive shop and noticed the operator anchoring a cylinder bushing preparatory to boring it out by means of two $\frac{5}{8}$ -in. chains, each with a clevis on one end and an eye bolt on the other. The clevis was made fast to the bracket of the bed plate, the chain then thrown over the bushing and the eye bolt put through the bed plate, with the nut on the under side, thus taking the place of clamps, blocks and bolts. Besides, the job is done in less than half the time and is more secure. I lost no time when I returned to my home shop to tell the operator of the arrangement. He at once ordered the chains, and now you could not get him to part with them.

We send foremen occasionally to other shops and they never return without bringing something that is an improvement over what we have. My experience has been when visiting shops that the officers in charge have always been glad to impart any information asked for, and also seem to take pride in showing their practice. If we feel that our methods are better than theirs we should say so.

We often get many good kinks from the supply men, as they have the advantage of seeing how work is being done in a great many shops, especially those who had been connected with the mechanical department.

Material

Material represents approximately 40 per cent of the cost of repairing and maintaining locomotives, a large part of which is purchased either rough or finished. Owing to the high cost of labor and the absence of modern and special production machines in many railroad shops, there are many articles which can be purchased finished cheaper than they can be manufactured on our railroads. There are also many articles sent from the purchasing to the mechanical department to be tested to see how they compare with home-made

articles, as well as to compare them with similar articles from other manufacturers. These tests should be given careful consideration, as they very often decide a standard for an entire system. Sometimes what is considered a successful article or tool in one shop is complained of by another. For that reason when an article is being tested it should be gone into thoroughly and passed on by competent employees.

Have any of us ever stopped to figure in dollars and cents the amount of labor which has been wasted on materials, such as hard castings, requiring twice as long to finish as it should? How often do we find, after spending many hours of labor on some piece of material, that it is full of blow holes or cracked? It has no doubt been passed on by the test department, but no matter how thorough they are they will not find all of the defects, especially in rough material. It is up to us to examine very carefully and to use good judgment in passing on material which is to be finished. True, the people we purchase the material from will replace the rough material, but they do not pay for transporting it back and forth to the store department, and from there the handling to the shop and back, or the amount spent for labor in the shop.

The mechanical department should work very closely with the store department on unsatisfactory material, calling their attention promptly to any article that is not standing up or giving the service that should be expected, so they can get in touch with the manufacturers for correction.

During the war period the locomotive costs have also been greatly affected, due to shortage of material, making it necessary to substitute all classes of material.

The mechanical department is to blame to some extent for this condition, due to the changing of patterns and specifications. These changes, no doubt, are paying propositions, but they tend to discourage the store department from carrying any large amount of stock. The mechanical department is also responsible for the great number of parts which the store is compelled to carry in order to supply the different styles and types of equipment, such as air brakes, injectors, safety valves and lubricator parts. Would it not be far cheaper to scrap the obsolete equipment, replacing it with standard material that will give better results and reduce the number of repair parts to be carried in stock?

We must check over our material and equipment, eliminating where possible, and we must bear this in mind at all times, not go over them once and then sit back and imagine that the job has been completed. It never will be as long as we operate railroads.

Another very expensive practice is the robbing of material from one engine for another. We not only pay for removing and replacing the part removed, but the chances are that it will cost more to apply the piece removed than it would to apply a new one. If each one of these items were traced down it will be found that if some one, whoever he may be, had been on the job it would not have been necessary. What per cent of the material we use does not give us the expected service because of other conditions? For instance, we will pack a piston rod half a dozen times, never getting it tight on account of an imperfect rod or the guides not going properly lined. If we had found out where the trouble was in the first place and corrected it we might have saved five sets of packing and the cost of applying them. This applies to many items used on our locomotives.

Material where carried in stock by the store should not be ordered before it is to be applied, especially small finished parts, as they will be thrown around and either broken or lost, necessitating ordering another piece which will double the cost. Shop people should be familiar with the cost of the different items of material they use. It is surprising to many good railroad men when they learn just what many small items really do cost, and probably they would think twice before saying, "Oh, throw it away and put on a new one."

An item of material where the quality has a great deal to do with the cost is the paint for locomotives. No matter how carefully or how scientifically it is applied, poor paint will not give good results and will have to be renewed much oftener than a coat of good paint. We are not painting our locomotives, especially our freight engines, merely to beautify them, but to preserve the material. An old coat of good paint is much better than a new coat of poor paint.

We should be far more efficient in the handling of material than labor, as the human element is not a factor to any great extent. If we watched more carefully the things we scrap there would not be so much material to reclaim. The more lax we are in scrapping material the better showing the reclaiming plant can make.

Manufacturing Locomotive Parts

The use of forging machines in our blacksmith shop certainly has worked wonders in producing forgings requiring very little or no finish, such as small side rods, eccentric rods, motion work, spring hangers and yokes, large hex nuts and other like material. I believe the blacksmiths take a great deal more pride today in doing their work so as to eliminate finish. For example, in main and side rods, the center sections are forged to size, requiring no finish except where the rods are channeled. Guide blocks should also be forged requiring no finish except where they fit on the cylinder head and one face for the guides and yoke. Guides also should be forged so as to eliminate as much finish as possible. Parts such as piston rods and valve stems should be cut to the proper length. Wedge bolts should be forged and the ends squared, so all that is necessary to complete them is to thread them in a bolt cutter. These were formerly made from bar stock on turret machines. Eccentric blade forks and ends and jaws for other motion work should be made allowing finish only where they fit on the links. Outside contours may be ground off. Eccentric blades for outside valve gears should be forged, allowing finish only on the sides, on the back end and for link fit on the front end. Large hex nuts and castle nuts should be forged and the holes punched, allowing very little finish. There are many other items where finishing can be reduced or eliminated if we only look for them, as the less number of operations necessary to produce a finished part the less the cost will be. Dies for this work are very expensive and should be taken care of, but they will pay for themselves many times over.

Castings

Patterns should be changed to reduce or eliminate finish where possible and changed from brass to cast iron or steel, or from cast iron to steel where parts are apt to break. If it is absolutely necessary to use brass, use it; if not, use either cast iron or steel. We are using many castings in the rough today which a few years ago we thought necessary to finish all over, such as side rod collars, wedge blocks and collars for main rods and strap middle connections, as well as many other small castings. On parts such as cast iron piston heads, allow finish only on the outside for cylinder size and the inside for the rod fit. Cast front cylinder and valve chamber heads with finish for the joint only. Core as many holes as possible and cast oil grooves in driving box brasses to save the time required to chip them. Core slots in driving box wedges for wedge bolts to size and maintain one standard for all wedges. All grate, side and center bars and supports, ash pan and grate shaker rigging castings, castings for tanks and front ends, cylinder cock and whistle rigging castings should be cast ready to apply on engines, with all holes cored and all castings the proper size and shape. The use of metal patterns is a help in securing good castings of the proper size and shape, as they will not warp or twist out of shape. Eliminate as much as possible finish on whistles, cab fixtures, blow-off cocks, boiler checks, cylinder cocks and valves, bells and yokes, relief valves, parts for piston and valve stem

packing, oil cups, swab holders, grease cups and plugs. Many of these items are used in large quantities and every little saving you can make will help to reduce our cost.

Where it is necessary to finish castings or forgings, be sure to allow enough finish, as it is much cheaper to remove $\frac{1}{8}$ in. than merely to scrape off the sand or scale.

Reclaiming Material

We have made wonderful progress in the last few years in reclaiming material. Although it will not be so noticeable in the next few years, the results will be as good if not better, as we are making a more careful study of the things which might be reclaimed and other places where we can use material which has been reclaimed. We are also making many special machines, such as rattlers for cleaning nuts and other small material, cutting shears and machines for straightening iron, special tools for cutting gaskets and washers from old leather and rubber. The electric and acetylene welders have also worked wonders in reclamation. Most of this material is reclaimed after reaching the scrap dock and is handled in most cases by a special reclamation department. There is another side to reclamation which is not so often heard of. This is the reclaiming of broken parts on locomotives without removing them or by removing, reclaiming and replacing on the same engine they were removed from. In most cases this is done either with the electric or acetylene welders.

There is very often a close margin between the cost of reclaiming a piece and purchasing and applying a new one. In these cases we should apply the new piece, as too often in figuring the amount which we save we try to make the figures look as attractive as possible without taking into consideration the life or wearing qualities of the reclaimed piece as compared with a new one. We must guard against letting our enthusiasm get the best of our good judgment. I venture to say that there are many parts being reclaimed today at a loss in dollars and cents in the long run; it is the cost per mile that tells the tale—both in material and labor. Other cases will actually show a great saving. One which recently came to my attention was a 10-wheel engine with a main wheel loose on the axle. The wheels were removed and the loose wheel pressed off. The wheel fit, which was $8\frac{1}{2}$ in. in diameter, was built up with the electric welder and turned off to $8\frac{5}{8}$ in., the wheel bored to fit and the old key way used in remounting. Boxes and eccentric straps were replaced, the wheels put up and the engine was ready for service in a very short time, saving not only a new axle but many hours of labor.

Where parts such as piston rods, valve stems and other like material have been reclaimed by building up for fits, they should be properly annealed before being turned to fit. Where rods or stems are worn close to the scrapping limit, or to the age limit if we have one, it is not advisable to reclaim them.

The practice of welding small broken cast iron parts which in the first place do not require much finish is not worth the chances you take of not getting a good weld. In many cases a new part will be just as cheap and much better.

As I look back through the years that I have been employed by various railroads I can plainly note the progress year by year, made possible both by more modern machines and tools and by improving our methods of doing work. Still our progress has not kept pace with the development of locomotives, which are now not only much larger but are equipped with modern appliances such as mechanical stokers, superheaters, feed water heaters, brick arches and power-reverse gears, all adding to the cost of maintenance. There is no comparison between the cost of repairing engines today and a few years ago. The average cost has increased year by year, but let us hope that by our united efforts we may make it possible by more efficient methods to stop the upward trend of this cost, as this is necessary before we can reduce it.

JIB CRANE FOR ENGINEHOUSE COLUMNS

BY NORMAN McLEOD

The problem of designing an efficient form of crane for facilitating the work around the front end of locomotives in engine houses has attracted the attention of motive power engineers for some time. It is believed that the defects in cranes of this class previously designed and illustrated in the *Railway Mechanical Engineer* have been largely overcome in a 4,000-lb. capacity jib crane which has recently been designed and is shown in the sketch.

This crane is so designed that by the employment of a compound or toggle joint as shown at A, the jib is allowed to travel the full circle of 360 deg., which gives this crane an obvious advantage over cranes having a lesser radius. Sudden shock and strains on the column are greatly reduced by

Jib Crane With Toggle Joint Support

having the bottom trunnion and its supporting bearing entirely free from the column and supported on a concrete foundation independent of the column. The location and fastening of the tie bars B allow the maximum travel of the hoist, which runs on the lower flanges of the 8-in. I-beam. When supported by a wooden post, the elasticity of the wooden column cannot cause this crane to get out of alinement to the extent of causing the bearings to bind as may happen with the usual type of jib crane. Provision is made for turning the crane in the swinging 1-in. wrought iron pipe hinged at C. The entire crane is made of structural steel with special castings as is shown in the drawing and requires no further description.

SIXTY-YEAR-OLD POWDER CAR.—The Nashville, Chattanooga & St. Louis which operates through a section of the country that figured prominently in Civil war annals has in service a car which is stated to have been used during the Civil war. It is a box car and was used for the transportation of explosives by the Union armies in their operations around Chattanooga and Atlanta and appears to have had an adventurous career. As an active agent in the war its work was brought to an end when it was dumped into the Etowah river by the Confederate general, Hood. It was, however, fished up and in due course was adapted as an express and baggage car. It has been in more or less continuous service and recently has been used on construction.

Refrigerator Car Gas Eliminating System

A SYSTEM for facilitating proper refrigeration of meat, vegetables or other substances subject to decomposition under ordinary atmospheric conditions, which is applicable alike to large or small ice boxes as well as to refrigerator cars, has been developed and is now controlled by the Acme Refrigerator Corporation, Chicago. This system, known as the Clinton Refrigerating and Eliminating System, is not in the ordinary sense of the term a refrigerating system. Its function is to remove from the atmosphere of the refrigerator the gases produced by bacterial action in the breaking down of the tissues of the product under refrigeration, and it is designed for use with any cooling system.

In all living animals there are myriads of active bacteria both toxic and anti-toxic. As soon as life is extinct, however, all anti-toxic activity ceases while that of the toxic

gaseous by-products resulting from bacterial activity, however, readily absorb moisture which is deposited against the cool surfaces of the product and the sides of the car. As a result of such condensation the car sweats and becomes moldy, and the moisture deposited on the surface of the product dissolves the serum film and increases the moisture content above the point at which the activity of all harmful bacteria is suspended. In the case of meats, the result is a slimy surface and an increased bacterial activity which breaks down and liquefies the solid protein material with the production of the acids CH_3SH and H_2S , both of which have disagreeable odors. Essentially the action is the same in the case of vegetable products.

The design of the Clinton Eliminating System is based on the principle that it is necessary to remove from the car the bacterial produced gases without lessening the efficiency

Details of the Clinton Gas Eliminating System

bacteria continues. Immediate chilling to a temperature below 40 deg. F. causes the activity of all acid producing bacteria to be suspended, with the result that the meat becomes coated with a firm serum film which will protect the product against the action of air-borne bacteria, provided the atmosphere surrounding the product is kept free from excessive moisture.

The action of bacteria on the product produces both heat and gas, the heat being removed by the circulation of the air over the cooling medium. The so-called tissue gas and other

of the refrigeration and circulation of the atmosphere within the car. The removal of these gases with their high moisture content produces a dry, clean atmosphere, the condition least favorable for bacterial activity and hence most favorable for the preservation of perishable products.

The gases produced by bacterial action, due to their difference in density as compared with the air, tend to stratify in the upper part of the car close to the ceiling, and the eliminating system makes use of this difference in density as the propelling force to remove these gases and replace

them with air from outside the car. The gases are collected in a shallow duct 13/16 in. deep, located just below the ceiling and open for the full width of the car near its ends. The duct is divided into two parts near the longitudinal centerline of the car, from each of which an outlet vent is led through the roof, the tops of the vents being located under the running board. These vents have an inside diameter of 1 1/2 in. and their continuity is broken in a chamber between the ceiling insulation and the roof of the car.

In order to effect the elimination of the gases collecting in this duct, provision must be made for drawing in an equivalent amount of fresh air. This is done through inlet vents in the ends of the car opening into thin air-tempering pans which are placed in the space between the end lining and the ice tanks. In the drawing these are shown to be 5 ft. 2 in. long by 2 ft. wide, and are only 3/4 in. deep. The vents through the ends of the car open into the pans near the top and the pre-cooled air is admitted to the car through openings just above the bottom on the sides facing the ice tank. The air is thus cool and dry before it enters circulation in the car. The amount of air admitted is only sufficient to replace the weight of the lighter gases collecting

in the top of the car and passing out through the outlet vents. As these gases are not only heavily charged with moisture but carry a considerable amount of heat resulting from bacterial action, the ease with which the proper conditions of refrigeration may be maintained is considered to be more than an offset for the amount of heat which must be removed from the replacement air.

As an inspection of the drawing will show, the Clinton Eliminating System consists essentially of but two parts, the gas collecting duct attached to the ceiling of the car and the ice tempering pans which are attached to the end lining of the car and occupy a portion of the space between the lining and the ice tanks. It will be seen that the system may, therefore, readily be installed in existing refrigerator cars with only minor alterations in the car structure to accommodate the inlet and outlet vents.

This system has been installed in a number of cars of the Cudahy Refrigerator Line. The service of this equipment during the last hot season was satisfactory in that it has demonstrated the correctness of the principle of the system as a means of greatly reducing the rate of decomposition of perishable products, and more cars are to be equipped.

Combustion Recorder for Flue Gases

IT IS a well known fact that the proportion of carbon dioxide (CO₂) alone in flue gases is not a sufficient indication of efficient boiler operation. This is true because the correct proportion of CO₂ varies with the kind of fuel used, the method of firing; the amount of air admitted, etc. For example, a proportion of 15 per cent of CO₂ might be allowable in one boiler installation, whereas another

America, Buffalo, N. Y., and is illustrated in Fig. 1. With the use of this recorder it is impossible for the boiler room force so to manipulate the dampers that a high CO₂ reading is obtained without showing up at the same time a high proportion of CO. The fuel must be so burned that the

Fig. 1—Installation of CO₂ and CO Combustion Recorder In Boiler Room

boiler, using a different kind of coal, would be operated most efficiently with a lower percentage of CO₂.

The presence of any carbon monoxide (CO) is an indication of inefficient boiler operation and the best way to be sure no CO is going up the stack is to measure it, simultaneously with CO₂. A combustion recorder that measures both CO₂ and CO has been developed by the Mono Corporation of

Fig. 2—Chart Showing Percent of CO₂ in Flue Gases

percentage of CO₂ is as high as possible without showing up any CO. In this way complete combustion is effected.

The device shown at the left of Fig. 1 is called the monoxide auxiliary type K, which, coupled with the stand-

Fig. 3—Chart Showing Percent of CO in Flue Gases

ard CO₂ recorder permits the recording of CO. Charts showing the proportion of CO₂ and CO are illustrated in Figs. 2 and 3. When taken simultaneously these charts give an accurate account of furnace conditions.

Machine for Milling Crosshead Keyways

A MACHINE designed to mill the keyways in all classes of locomotive crossheads and piston rods, has been placed on the market recently by the Garvin Machine Company, New York. The two keyway slots in a steel crosshead vary in size up to 1 7/8-in. wide by 4 7/8-in. long by 5 in. deep and the difficult job of machining them is readily

feeding. The work moves and the cutters are fed in from each side.

A fixture is provided to hold the crosshead on a mandrel, as illustrated, with some adjustment lengthwise, and a rear block to register the angular position of the keyway with the guide ways. The same fixture is used for the piston rod, but with a diagonal tongue piece to give the required taper. This fixture is used for all sizes by bushing down. The work is mounted on a heavy table and traversed by an adjustable crank pin and block, both hardened, moving in a hardened slot carried on the bottom side of the table. The crank stands vertically and is driven by a large bronze worm gear running in oil.

The cutters are held in two sliding sleeves carried on adjustable headstocks fitted to the bed. The heads can be run back to get the cutters out of the way when mounting the work, and then run forward to fixed stops. Each sleeve has a maximum feed of six inches and an automatic trip. The cutter sleeves are run forward and back simultaneously by hand, by a large handwheel at the front. The cutter spindles are fitted with positive driver slots for cutters and the front bearing is tapered, running in a solid bronze box. The rear bearing is straight, fitted with an adjustable bronze box.

The bearings of the sleeves in the heads are split the whole length to regulate the tightness of the sliding fit. The in-feed of the cutters takes place at each end of the stroke, and varies from .010 in. to .025 in. by an adjustable pawl and ratchet. An automatic trip is provided to lift the pawl out of action and stop the feed of the cutters when the proper depth is reached. The machine is driven by two five-horsepower, three to one variable speed motors with push button control, arranged so that if one motor fails the other will stop. All feeds and drives are positive except the oil pump.

Rear View Showing Motor Drive, Change Gears and Angular Positioning Block

accomplished on the machine illustrated at the rate of one crosshead per hour. A 5 1/2-in. piston rod keyway can be machined in one hour also, as has been demonstrated on one of these machines installed in a large railway shop in the

Garvin No. 3 Duplex Slot-Milling Machine

east. With piston rods, the work is swung around at an angle to provide the necessary taper; and when the slot is nearly through, one cutter automatically retreats and the other continues to advance, completes the slot and then stops

The adjustable crank for moving the table can be adjusted by a wrench at the rear and set by a scale on the moving table.

Change gearing is provided to regulate the number of

strokes per minute of the table in relation to the length of slot and diameter of cutter being used. The cutters run 70 ft. a minute, with a maximum in-feed of .020 in. on large cutters, two-prong fish-tail cutters being used. The table moves at the rate of 18 in. per minute at mid-stroke. For milling a through slot as in a piston rod, the right-hand head carries a special screw that can be thrown into action, and this screw advances towards the right at the same time that the sleeve feed screw is advancing towards the left. At the proper time the feed nut of the sleeve screw is unlatched and the special screw meets the feed screw head, pushing the feed screw and spindle sleeve back bodily; while the left-hand cutter continues to advance. When the

left-hand cutter has cleaned up the slot the automatic trip lifts the feed pawl out of action. The feed nut is relatched and the cutters resume their original positions, when the cutters are run back by hand.

A strong stream of lubricant to wash the chips out of the slot is provided for each cutter with a necessary oil trough and reservoir. Intermediate cloth gears are used to reduce noise and all gearing is thoroughly protected. The method here used of light cuts and fast traverse is more rapid than heavy cuts and slow feed, and is not limited so much by the depth of cut. The machine can be used for cutting keyways, cutting out fork ends in rods and other work of a similar nature.

Laminated Glass for Car Windows

A NEW type of laminated safety glass has been invented recently and placed on the market by E. I. du Pont de Nemours & Co., Inc., Wilmington, Del. This glass consists of two sheets of ordinary glass, between which is interposed a thin sheet of pyroxylin plastic. Hydraulic pressure and the application of the proper degree of heat welds the glass and the pyroxylin sheet together in a solid unit. The pyroxylin binder prevents any scattering of fragments in the event of violent breakage of the glass.

In a recent test, a nickel jacketed revolver bullet fired from a distance of seven feet failed to penetrate a sheet of this laminated glass. The transparency of the glass, it is claimed, is not appreciably reduced by the insertion of the plastic sheet. It is proposed to introduce the glass extensively for use in car windows or wherever fragments of broken glass will cause personal injury, should a window be broken either accidentally, or maliciously, as by small boys throwing stones.

Hoosier Plain Drilling Machine and Vice

A 16-IN. plain drive vertical drilling machine designed for light and medium work has been developed by the Hoosier Drilling Machine Company, Goshen, Ind. Maximum simplicity together with convenient operation has been secured in this machine. All gears are machined and carefully fitted. Particular attention has been paid to the spindle alignment and to securing ample lubrication of all bearing surfaces. The drill is driven by a belt from the main shafting and is started and stopped by means of a foot-operated belt shifter. Cone pulleys provide a range of five spindle speeds. Either a round or square table can be provided.

body a milled key slot runs the entire length of the body and insures correct alignment when the vise is anchored

It is possible to drill to the center of a 16-in. circle, the

An Adaptable Vise of Rugged Construction

distance from the column to the center of the spindle being eight inches. The maximum distance from the spindle to the table is $28\frac{3}{4}$ in. and from the spindle to the base $44\frac{3}{4}$ in. The spindle travel is $8\frac{1}{2}$ in. The machine consumes about one horsepower and the speed of the driving pulley should be approximately 300 r.p.m. This allows a range of spindle speeds including 46, 172, 300, 521 and 971 r.p.m.

Detachable Vise

The vise illustrated is intended for use on drilling and milling machines, but can be used with equal success on shapers or planers. Like the vertical drill described above, the vise is simple in construction and strong. The jaws are faced with hardened steel. On the bottom of the vise

Hoosier 16-Inch Vertical Drill

to a milling machine table. Flanges with bolt slots are provided on the body of the vise so that it may be securely anchored to the table.

North Pole Sanitary Drinking Fountains

THE Henry Giessel Company, Chicago, Ill., has developed and placed on the market several types of drinking fountains that have proved to be a sanitary and economical part of railway equipment. These fountains are of very substantial construction, effect a considerable saving in

that only the water that is being used is cooled, thus effecting a great saving in the amount of ice required.

A fountain designed for use in mail cars which is made with or without a filtering apparatus is also shown and, being similar in construction to that used for passenger coaches, furnishes the employees of the railway mail service with sanitary drinking water. The fountain proper consists of a storage tank for filtered water and an ice compartment in the bottom of which is placed the cooling pan through which the water flows from the storage tank to the faucet. The water supply is drawn from the overhead tank of the car and, by gravity, passes through the filter on the top of the fountain into the storage tank and thence into the cooling tank.

These fountains require no steaming or cleansing during

Special Cooler for Locomotive Tenders

the amount of ice used and require only a minimum of attention at terminals.

There are several designs of this fountain for use in passenger carrying equipment, one of the latest types being shown in the illustrations. The fountain for passenger

Porcelain Enameled Fountain for Passenger Coaches

Fountain for Mail Cars Type Used in Baggage and Express Cars

train operation as all that is necessary is to change the filter stones at terminals every seventy-two hours, simply replacing the stones with freshly sterilized ones. This operation requires only about ten minutes per car, the thorough cleansing and sterilizing of the entire apparatus being necessary only at infrequent intervals as the use of freshly sterilized filter stones meets all of the sanitary regulations in the various states and has been favorably passed upon by the United States Board of Health. However, provision is made for convenient and thorough cleaning of all parts of the cooler. By the removal of five clamps, the filter casing may be removed and the filter stone taken out by unscrewing the pipe connection with which it is attached to the fixed end of the filter case. It is then easily and thoroughly cleaned by steam or by submerging in hot water. An opening is provided on

coaches consists of a filter, shown at the top, a storage tank having a capacity of seventeen gallons and an ice chamber containing a cooling pan with a capacity of three cups so

the front of the storage tank near the bottom which is closed by a plug. Removal of this plug permits the interior of the tank to be cleaned by the insertion of a steam nozzle.

To drain the system, a cock is opened in the bottom of the cooling tank which permits the water in the storage tank to flow directly into the ice chamber and thus out through the drain.

An adaptation of this fountain for baggage, express and other cars where drinking water may be required is also shown which, in addition to the supply of drinking water, provides a tank for wash water.

In addition to the three tanks already mentioned, this company also manufactures a portable tank for locomotive tenders. This tank has an ice compartment as in the other fountains and thus provides pure water without contamination from ice which may be secured from sources where it is impossible to eliminate cinders or other impurities. In this tank, the melted ice drains off and, as only a small por-

tion of the water is in contact with the ice at any one time, the economy of the cooler is apparent. As shown in the illustration, a bracket is permanently attached to the tender and sockets are provided on the tank so that it may be securely suspended from the bracket and thus withstand the shocks incident to the operation of the locomotive.

A filter operating in a manner similar to the filter used with these fountains, is manufactured by the Giessel Company for use in conjunction with the Giessel standard cooling pan and makes a complete filtering and cooling apparatus for dining cars. These filters and fountains are in use on a large number of railroad cars on a number of the larger railroads in the United States and observations made by two of the largest roads show that twenty-five pounds of ice is sufficient for a run of five hundred miles. These fountains are made of cast iron, white porcelain enameled, are easily kept clean and add to the interior finish of a car. They are economical in the use of ice.

Alligator Shears for General Work

A LINE of alligator type shears which can be used to good advantage in railway blacksmith shops, scrap docks and reclamation plants, has been developed and introduced recently by Doelger and Kirsten, Milwaukee, Wisconsin. The machines are made in four sizes with jaws varying from 21 to 30 in. long and bar stock up to 5 in. square can be cut on the No. 4 shears. The ma-

chine from either side and it is possible to cut boiler plate as well as bar stock. Large gears on both sides of the crank shaft, are used as drive gears and their size and weight insures a strong, well balanced drive. The automatic arrangement by which the machine stops at each stroke, allows sufficient time for careful measurement of the work before the machine is again operated.

Alligator Shears Cut Round Stock at an Angle Without Deformation

chine, illustrated, is exceptionally rugged in construction and designed to withstand all stresses incident to the severe nature of the work performed.

An important feature in the construction of this line of alligator shears is found in the automatic attachment by means of which the operation of a foot lever trips the clutch and causes a full stroke, the machine stopping automatically at the end of the revolution. The work may be fed to the shears

Particular attention is called to the arrangement by which round stock can be cut at any angle up to 30 degrees. This feature is of value for many operations as, for example, in the manufacture of chain links. Doelger and Kirsten No. 4 alligator shears have been installed at one plant to cut 5½ inch round iron bars at a 30 degree angle in making chain links. In this case, a clean cut surface for welding is secured and no loss of time occurs due to the blacksmith form-

ing the 30 degree angle on each link by hand. Cutting the stock at any angle is made possible by the use of suitable dies. The dies required depend upon the kind of work desired to be done and they are essential particularly in cut-

ting round stock. With the dies, it is possible to cut round stock well within 5 per cent of the perpendicular and the end of the stock is not deformed. This feature is particularly valuable for certain kinds of work.

Motor-Driven Automatic Hob Grinder

THE latest addition included in the line of precision grinding machines manufactured by the H. E. Harris Engineering Company, Bridgeport, Conn., is an automatic hob grinder. This machine is furnished either as a belt- or motor-driven machine, the former being called No. 815-B and the latter No. 815-M. On account of the many advantages of machines equipped with unit motor drive the No. 815-M machine illustrated is a favorite with shop fore-

Harris Automatic Hob Grinder Arranged for Motor Drive

men and managers. It can be set up in the most convenient position, irrespective of shaft or group drive.

The motor for driving the wheel spindle is mounted above and upon a circular horizontal slide, the wheel head being mounted below on the same slide. The drive from motor spindle to wheel spindle is by an endless belt, the slack being taken up by raising the motor itself. This motor does no work except to drive the spindle and sudden torques from reversing or indexing do not affect it. The cutting face of the grinding wheel coincides with the vertical axis of the horizontal circular slide, so that when this slide is swiveled to the desired angle of the hob flute, the wheel is in the correct position. The weight of the motor adds to the stability of the machine and helps in absorbing vibration. Better results can be secured with this type than with the belt-driven machine. The ball crank handles, shown on the right of the column, control a fine and powerful vertical and horizontal adjustment to the wheel head.

For driving the automatic slack take-up device, the in-

dexing mechanism, the self-priming pump and the table feed and reverse, a separate motor is located behind the machine base. The machine is provided with full automatic features throughout, including indexing, reversing, feeding the hob a predetermined amount after each revolution, and stopping when the desired amount has been ground off.

Hobs not exceeding 8 in. in diameter by 10 in. long can be ground. It makes no difference whether the flutes are straight or spiral, both right and left hand spindles being taken care of by the ball crank handle on the left of the machine. This controls a fine adjustment through worm gear, pinion and sector to the forming slide, which is coupled to the work spindle. The hob rotates the required amount to provide helical movement during the longitudinal movement of the work table. The adjustment can be made while the machine is running. Indexing is done automatically.

The table travel can be operated either by hand or automatically. The short lever on the extreme right controls the

View Showing Handles for Wheel Head Adjustment

automatic table feed and reverse mechanism. A diamond truing device is arranged for truing either side of the grinding wheel to any angle required, also the periphery of the wheel. It can be used without interfering with the set up of the hob or cutter in the machine.

After the hob has been set up and the machine started, an automatic adjustable feed is provided which will grind off the face of the teeth the required amount at each stroke. Provision also is made so that a predetermined amount may

be ground automatically through successive revolutions, when the machine stops automatically.

One unusual feature of the machine is an ingenious device providing a uniform pull to take up all slack in the spindle indexing and spiral generating mechanism. This permits the grinding wheel to operate on both strokes.

It is claimed that by the use of the Harris automatic hob

grinder the life of hobs will be increased materially, for the cutting teeth are accurately and evenly ground, the minimum amount of material is ground away at each stroke, there is no crowding or burning of the hob teeth and the profile or temper of the teeth is not destroyed. An ample supply of cutting lubricant is furnished and provides greatly increased machine output when necessary.

Grease Lubricator for Journal Boxes

A DEVICE for holding and distributing hard grease to car journals has been developed for application to the standard journals and journal boxes in place of the usual oil soaked waste packing. It has been tried out successfully in passenger service.

The illustration shows the form of the lubricator and the method of applying it to the journal box. The lubricator consists of a brass casting, the grease reservoir extending up in front of the journal collar and the distributing surface being fitted to the under side of the journal bearing. It is held in place against the journal bearing by two coil springs, the upper ends of which fit over lugs on the bottom of the lubricator, while the lower ends are held in position over lugs on a plate, resting on the bottom of the journal box. In an opening in the face of the lubricator bearing against the journal is fitted a small roller which serves partially to distribute the grease to the journal surface. Grease is also fed to the journal through holes drilled through the bearing surface of the lubricator. The journal is protected from dirt by two pads attached to the sides of the lubricator, extending upward against the sides of the journal to the lower edges of the brass. These shields or pads also serve to hold and distribute the lubricant over the journal when it is in motion.

Like all grease lubrication, the operation of the device depends on a sufficient rise of temperature of the journal to soften the grease and permit it to flow freely. The reservoir opening, located in front of and at about the center of the

A Journal Box Lubricator Using Hard Grease

journal collar, is readily accessible for refilling by opening the journal box lid.

The patents on this device are owned by T. J. Holmes, Chicago.

Screw Thread and Gage Checking Machine

CONVENIENT and accurate means for checking the measurement of screw thread tools, formed tools, gages, etc., is provided by a microscopic measuring machine which is being introduced to the American market by Alfred Herbert, Ltd., Coventry, England. The machine is well adapted for measuring lengths, angles and pitches. It does not depend on screws for its accuracy, but upon end measuring rods and large dial micrometers. It consists of two main parts, including a rigid box-bed carrying a table capable of 12-in. movement by accurate amounts through the insertion and removal of standard hardened steel measuring rods of known length between flat contact pieces. A pair of centers also is provided, one of which is adjustable in a crosswise direction to enable work to be lined up accurately.

The other part of the machine consists of a microscope with vertical movement by means of a rack and pinion for focusing, and mounted on a compound slide rest, with screw movement parallel with the slides and at right angles to the table slide. The microscope is fitted with two hair lines across its diameter, one rotating with the outside tool and the other rotating with the eyepiece. The outer tube carries a large dial, carefully graduated in half degrees, and the eyepiece carries a vernier, which enables readings accurate to one minute to be made. Thus the angle between the two hair line can be indicated with great accuracy.

A light projector is fixed to the machine to project parallel rays of light through a lens onto a mirror placed at an angle, and so past the work. When measuring threads this attachment eliminates all shadows and the light projected from the flanks of the thread which tend to make the object indistinct. The mirror is adjustable to suit the lead

of the thread and enables the object to be clearly defined through the microscope.

In making a plain length measurement the work is clamped on the table and the table is clamped to the bed with a measuring rod held firmly between the two contact pieces. The microscope is then focused on one end of the

Herbert Microscopic Measuring Machine

piece or part to be measured, with the hair lines covering a defined point from which the measurement will be made. The measuring rod is then substituted by another and the table adjusted and re-clamped. By looking through the microscope it is quickly seen whether the part to be measured

corresponds with the difference between the lengths of the two measuring rods. If it varies, the compound slide can be adjusted until the hair lines cover the second point that should have come immediately under them if the part had been correct. The micrometer on the compound slide registers the error.

For the checking of gages, master templates, pitch, depth and shape of screw threads the machine illustrated is exceedingly accurate. All angles are checked by angular adjustment of the hair lines and irregular shapes are checked by a series of straight line measurements combined when necessary with adjustments of the hair lines.

Turret Tool Post for Engine Lathe

A TURRET tool post, designed to be used on engine lathes, has been produced recently by the Lovejoy Tool Company, Inc., Springfield, Vt. It is rigidly constructed, convenient in operation and compact enough to be used on any lathe having a center height above the tool rest

of over 1 $\frac{3}{8}$ -in. A positive lock is incorporated in the turret. The turning and facing cutters are adjustable for height as they become worn; this feature permits of keeping the cutting edge on center without sacrificing strength and rigidity. The tool overhang has been reduced to a minimum.

Lovejoy Turret Tool Post

By one movement of the binding lever the operator releases, accurately indexes to the next tool post, and again rigidly clamps the turret to its base, an operation quickly accomplished by one hand. The turret rings are approximately 4 $\frac{3}{8}$ in. square, made of hardened steel and are interchangeable on any base. This feature permits the use of additional rings, carrying a variety of tool combinations for various jobs. One of the rings is provided with boring bars one inch in diameter as shown in the illustration. These are entirely free from projections to interfere with chip clearance and will cut to the bottom of a hole slightly larger than the bar itself. The toolpost will instantly interchange with any regular engine lathe toolpost without special fitting of the lathe. It is only necessary to submit dimensions of the toolpost saddle with the order.

Motor Drive Applied to Power Hammers

CONVENIENT arrangements of motor drive applied to the power hammers manufactured by C. C. Bradley & Son, Inc., Syracuse, N. Y., are shown in the illustrations. Where there is an objection to the use of overhead

motor and hammer. Pressure on the foot treadle engages the idler and starts the hammer, also regulating the force

Bradley Hammer With Driving Motor Mounted at the Side of the Machine

200-lb. Bradley Hammer With Driving Motor at the Rear

shafting or where the blacksmith shop is isolated from the main power plant this arrangement can be used to good advantage, a compact and efficient motor drive being secured.

The motor is mounted on a block adjacent to the machine and drives through a loose belt and idle pulley between the

of the blow. On the 200-lb. hammer, a counterweight balances the idle pulley. This insures that practically all pressure applied to the foot treadle is transmitted to the idler.

Adjustable Limit Gage Aids Inspector

ONE of the latest gages produced by the John M. Rogers Works, Inc., Gloucester City, N. J., is the adjustable limit snap gage illustrated, which is convenient for accurate inspection work. Gages of this type are made in 22 different sizes, the smallest of which has a range of from 0 to $\frac{1}{4}$ in., while the largest has a range of from 8 to $8\frac{1}{2}$ in. The frame of the gage is double ribbed to afford extreme rigidity, a most important feature in a tool of this kind. The anvils are made of alloy steel, hardened, ground and lapped to afford durability and accuracy. Marking tags showing the sizes are made in the form of separate brass plates screwed to the frames of the gages, and extra tags may be furnished when they are required.

Before being machined the malleable iron castings are well seasoned to guard against warping after the gages have been finished. All of the gage plugs are carefully lapped, both on their diameters and gaging surfaces. This accuracy in sizing the diameters of the plugs enables them to fit snugly into the holes in the frame, which are line-reamed to assure parallelism. The plugs are so designed that they cannot turn in the frame. The adjusting screws have a fine pitch thread, which permits of making accurate adjustments. A master locking device in addition to firmly setting both anvils with one master screw can also be set to hold a slight tension equally on the anvils while adjust-

ments are being made. When the master locking screw is firmly set the space provided over the head may be sealed, making the gage proof against tampering.

It is an easy matter to set the plugs to any dimension

Rogers Adjustable Limit Gage

within the range of the gage by using a standard measuring plug block, or disk. When the plugs become worn and require repairing it is only necessary to grind the ends on the wheel and lap the surfaces down perfectly square.

Crank Shaper With Wide Cross Rail Guides

THE 20-in. back geared crank shaper, described and illustrated in this article, has been placed on the market recently by the Whipp Machine Tool Company, Sidney, Ohio. This machine is made in 16-in. and 20-in. sizes

Particular attention is called to the arrangement for supporting the cone pulley shown in Fig. 1. In this design the

Fig. 1—Whipp 20-In. Crank Shaper

Fig. 2—Showing Unusual Width Between Cross Rail Guides

and a particular feature is the unusual width between the cross rail guides, more plainly indicated in Fig. 2. The wide guides on the column form a pair of external ribs, which provide unusual column stiffness and rigidity. At the same time, a wide guide is provided for the cross rail itself, so that the work never overhangs the guides.

hub of the cone pulley is flush with the small end of the cone which allows the bearing in the column itself to extend nearly to the center of the cone. This assures a much stiffer

bearing than would be the case where an outboard support or sleeve bearing is used. Correct alinement of the pulley and shaft is maintained under heavy belt pull, a most important advantage.

An eccentric locking bolt is provided for locking the swivel plate to the head. This holds the head solidly to the ram and at the same time provides a quick and easy method for releasing when the head is to be swiveled.

The shaper base is arranged to prevent oil from dripping on the floor. Extension of the ram guides at both the front and rear of the column provides a long ram bearing and to secure accurate alinement, the elevating screw nut is carried in the main column casting. A table support may be furnished with the shaper and applied to the base extension as illustrated. This arrangement increases the rigidity of the table under heavy cuts.

New Driving Arrangement for Hand Planer

Hand Planer and Jointer Arranged for Direct Motor Drive

FOR some time hand planing and jointing machines placed on the market by the Oliver Machinery Company, Grand Rapids, Mich., were arranged with the motor built into the machine. This arrangement, however, did not permit of sufficient flexibility, inasmuch as the machine could be used only in a shop provided with the particular electric circuit for which its motor was designed.

In order to overcome this difficulty a new type of drive connection has been developed, which permits the use of any type of electric motor, provided its speed is approximately 3,600 r. p. m. In other words, the machine illustrated can be furnished with a motor to operate on direct current, or alternating current, with single, two, or three-phase voltage.

All belting is eliminated since the motor is directly connected to the revolving cutter head. The efficiency of the machine is increased on account of fewer bearings and no belting and the absence of belt guards saves considerable floor space. The machine is equipped regularly with three high speed knives in the head, which is of the Oliver round or safety type. On account of the high speed, the machine above described is capable of producing smooth work required in cabinet shops and pattern shops.

Pipe Bending Machine Is a Labor Saver

LOCOMOTIVE construction and repair work in particular, require a good deal of piping and in these days of high labor cost it is important that all shops be equipped with power-operated, pipe bending machines. The pipe bender, illustrated, is made by the Wallace Supplies Manufacturing Company, Chicago, and has a capacity to bend cold pipe up to two inches in diameter. Ordinarily no inside follower or floating mandrel is necessary, but these can be used when bending special forms.

The standard equipment furnished with the machine consists of four forming heads which may be used for bending one-inch iron pipe to an angle of 90 deg., with a six-inch radius; 1¼-in. pipe to an angle of 90 deg. with nine-inch radius; 1½-in., 90 deg. with 12-in. radius; 2-in., 90 deg., 14-in. radius. The pipe is secured to the form by means of a strap as indicated, and both the follower and the form are grooved with the proper clearance to secure the best results.

The outside follower bar operates between the tube and the roller instead of the roller working directly on the tube. This method supports the tube for a greater distance and obviates the depression which usually shows on the tube when the roller operates directly on the materials. The roller bracket is adjustable to take forms up to 50 in. in diameter and is operated on a screw to force the tube into the form and for holding the follower bar close to the tube. This is necessary in order to secure the best possible results.

The machine is operated by lever for forward and reverse friction clutch pulleys, with adjustable stops provided to suit any degree of bend required. The clutch is automatically thrown out of engagement at both the end of the bending operation and when the machine has been reversed to

Wallace Pipe Bending Machine

the starting position. Special forms with inside follower bars or floating mandrels can be furnished to order for bending light gage tubing to a short radius without flattening or crimping.

Horizontal Drilling and Boring Machine

A HORIZONTAL drill designed to cover a wide range of drilling and boring operations at one setting has been developed recently by the Milwaukee Electric Crane & Manufacturing Company, Milwaukee, Wis. By the use of this machine, it is possible to perform drilling operations on castings too bulky for the usual type of drill. Double setting of the work is avoided with a considerable saving of time, and the elimination of errors when boring holes for shafts or bearings, required to be parallel. Greater durability and accuracy in operation, as well as a more rapid change in speed and manipulation, has been secured by means of a direct-connected variable speed reversible motor. The arrangement illustrated provides high durability and efficiency and eliminates the use of gears in transmitting power from the motor to the spindle.

The spindle is of high carbon steel, accurately finished, the front end being fitted with a ball thrust bearing and a No. 5 Morse taper hole. Arrangement is made by means of a special cross key and nut for drawing up and releasing boring bars or tools. The spindle torque is not transmitted through the tang of the drill socket or boring bar when the work is heavy. The heavy rack teeth are arranged to automatically cut out the drive when the spindle reaches the extreme feed range. Danger of stripping the feed mechanism is thereby eliminated. The spindle is geared for standard speeds of 20 to 400 r.p.m. With a four to one motor speed range and 16-point controller, 32 different speeds are obtained with a single back gear ratio of five to one.

Six spindle feeds are provided for this drill from .009 in. to .070 in. per revolution. The feed is cut in or out by means of a trip lever and quick return or advance secured by the handwheel on the quill pinion shaft. The carriage elevating and lowering mechanism is operated by power or hand and the driving gear is provided with a limiting torque clutch as a safety feature. The hand adjustment is used only to secure final setting of the carriage. A steel scale on the face of the column indicates the distance from the top of the table to the center of the spindle.

The standard table furnished with the machine is 4 ft.

wide by 9 ft. long and slides on a heavy planed cast iron bed. The table is power operated by a heavy screw capable of easy and accurate adjustment from both sides of the work. Suitable T-slots are provided for clamping the work or fix-

Milwaukee No. 25 Horizontal Drill Driven by 5-Hp. Motor

tures. All control levers are placed on the spindle carriage within convenient reach of the operator.

Small Pneumatic Hand Drilling Machine

FOR drilling staybolt telltale holes and other small holes, a drill developed by the Desoutter Brothers, Ltd., London, can be used to good advantage. The machine, shown in Fig. 1, is of novel design and takes the

form of a cylinder 4 in. long by 1½ in. diameter, with the chuck protruding. It weighs only 1 lb. 14 oz. and takes drills up to ¼ in. The tool is grasped in the palm of the hand and the air supply is controlled by a press button in the head of the drill. The motor consists of a block of

Fig. 1—Desoutter Pneumatic Hand Drill

Fig. 2—Hand Drill Disassembled

five cylinders, of 7/16-in. bore and 1 1/8-in. stroke, arranged symmetrically with respect to a control axis, with their bores 1, Fig 2, parallel.

The piston for each cylinder is hollow and the working faces 2 are cut on the lower end to fit a specially shaped cam 3. The cam is mounted so as to rotate about the central axis partly inside the recessed portion of the cylinder block, the pistons being operated in succession, controlled by a rotary type distribution valve 6. This valve works on the circular valve face in the center of the cylinder head 11. As each piston reaches the top and then the bottom of its stroke, the valve automatically admits air in the first case and permits the exhaust to take place when the bottom of the stroke is reached. This occurs with each cylinder in succession. There being five cylinders and pistons, a continuous motion is thus given to the cam. At the bottom of each stroke two small ports are exposed in each cylinder, which allow oil to be blown onto the cam face and ball race. The cylinder heads, valve face, inlet and exhaust ports are all in one piece, 11.

The cam rotates in a large ball bearing of which it forms the central member. Two large diameter outer races, fitted

with balls of ample size, complete the essentials of the bearing. The thin steel ring, 5, is a distance piece clamped between the outer races and forms the only adjustment required. The internals of the drill are kept in place by the screwed control valve housing 9 and the screw disk 10. The chuck is kept on by a taper fit and screw.

An important factor in the efficiency of the drill, as far as air consumption is concerned, is the arrangement of employing one valve to control five cylinders, thereby reducing leakage to a minimum. Loss of air is also prevented by having the valve ports directly on top of each cylinder. Friction on the valve face is reduced to a small amount by a special balancing device. The form of construction of the cylinder block presents a means of getting the maximum power in the smallest space practicable.

The control valve is of the slide valve type, controlled by a push button. The rod of the press button acts as a piston, working through a small leather gland, the working pressure being used to force this outwards, thus automatically closing the control valve. The drill is well adapted for use in sheet metal shops and in fact any shop having many light hand drilling operations.

Pyrometer Recorder for Tool Room Use

MOST modern railway tool rooms are, or should be, provided with heat treating equipment including pyrometers, but in many cases no arrangements are made for pyrometer recording instruments. Several installations already made of these instruments have proved their value as an effective check on the tool maker. More uniform

sensitive moving system, carefully protected against accident, is mounted. In the front compartment, the clock and depressor bar mechanism as well as a direct reading scale is mounted, as indicated in the illustration. This construction eliminates danger of breakage if inexperienced or careless men replace the charts.

Engelhard Pyrometer Recording Instrument

The charts are of the continuous roll type, approximately 100 ft. long, which allows records of practically any desired time length to be kept. The time-temperature lines are at right angles to one another, thus forming rectangular coordinates and a strictly proportionate chart. The temperature lines run longitudinally on the chart and the time lines across. The clock is provided with double main springs furnishing ample power and the chart drum, which drives the chart at its specified rate, is geared to the clock by interchangeable gears. Records are formed by a series of dots, an interval between dots corresponding to one minute. Therefore, on a four record instrument, a record is made on each thermo-couple once every four minutes.

A color carrying roller is located near the front of the instrument, just in back of and below the scale. It runs straight across the instrument, the chart coming up in back and over the color roller. The pointer swings just above the chart. Above the pointer is the depressor bar with its straight edge directly above the center of the color roller. When a record is formed, the depressor bar is allowed to fall upon the pointer of the instrument. It causes a record of the position of the pointer to be made by pressing the pointer against the chart beneath and squeezing the chart paper between the pointer and the color roller underneath the chart. A small quantity of the pigment is taken up on the under side of the chart, which is transparent, allowing the color to show through clearly.

All contacts in the thermo-couple circuit are of silver with a heavy gold plate. The operation gives a wiping effect, insuring perfect operation of the contacts. Simplicity combined with careful design and construction of the pyrometer recorder insures accurate results and long life with reasonable care in handling.

and better results in the heat treating of tool steel have been secured.

A recording instrument designed to record temperatures registered by pyrometers has been placed on the market recently by Charles Engelhard, New York. With the idea of making it as thoroughly fool proof as possible this instrument is divided into two compartments, in one of which the

CO-OPERATIVE STORES.—Information on how to start and conduct a co-operative store may be obtained from the Co-Operative League of America, 2 West Thirteenth street, New York.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the *Railway Age*, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, east of the Mississippi river, \$3.00 a year; west of Mississippi river and Canada, \$4.00 a year; elsewhere \$5.00, or £1 5s. 0d. a year. Foreign subscriptions may be paid through our London office, 34 Victoria Street, S. W. 1., in £ s. d. Single copy, 30 cents.

WE GUARANTEE that of this issue 10,600 copies were printed; that of these 10,600 copies, 9,766 were mailed to regular paid subscribers, 13 were provided for counter and news company sales, 259 were mailed to advertisers, 32 were mailed to employees and correspondents, and 530 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 94,650, an average of 11,831 copies a month.

THE RAILWAY MECHANICAL ENGINEER is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

It has been estimated that the value of the total output of machine tools in Great Britain during 1919 was about £10,000,000.

Employees in the machine and car shops on the Santa Fe system have agreed to work nine hours per day, instead of eight, beginning July 19, until the shortage of equipment is overcome.

The Chicago, Milwaukee & St. Paul car repair shops at Milwaukee, Wis., were destroyed by fire on July 18. The building was 600 ft. by 1,500 ft. and the estimated loss is \$250,000. More than 100 freight cars were also destroyed.

A request of Cincinnati machine tool builders that Chinese students be admitted to this country to learn the machine tool trade has, it is understood, been refused by Louis F. Post, assistant secretary of the Department of Labor. The decision not to admit the Chinese was made by Mr. Post on a strict interpretation of the word "student."

The Speedograph locomotive recording chart shown on page 489 of the July *Railway Mechanical Engineer* was erroneously stated to cover a period of four hours, instead of two hours as is really the case. The recording tape is calibrated in minutes and there are 120 of the smallest divisions, making a total of 120 minutes or two hours.

While the Illinois Central had a number of cars of the compartment type like those found generally in Europe in the Chicago suburban service, it is learned that 50 new steel coaches now being built for that company's suburban service have end doors only. These cars are being so constructed as to be available for conversion to electrical operation when the company's electrification scheme is completed.

The board of directors of the Manila Railroad Company, which operates 647 miles of track in the Philippine Islands, nearly all on the island of Luzon, has authorized the expenditure of \$2,500,000 for new equipment and betterments. The directors approved requisitions for 30 new locomotives, 100 thirty-ton freight cars and 25 additional passenger coaches. Bids for furnishing this equipment will be opened soon in New York.

The decennial celebration of the establishment of the United States Forest Products Laboratory at Madison, Wis., was held in that city on July 22 and 23, at which time an

opportunity was offered to make a detailed inspection of the laboratory and of the work which it is doing. A program was also presented at which the work of the laboratory was reviewed and conferences held to promote the interests of forestry in this country.

Cable advices from Tokyo, under date of July 7, received in banking sources in New York say that a bill has been introduced by government in the Japanese Parliament creating the Imperial Electric Railway Company. The aim of the bill is to establish electrical power supply for railroads and to gradually convert steam railroads to electric. Capital will be 100,000,000 yen (\$50,000,000), of which one-half will be invested by the government.

During the month of May 152 locomotives were exported, valued at \$5,906,046. From the standpoint of value this represents the greatest export of locomotives for any month this year to date. The exports of freight cars in May totaled 1,884, valued at \$3,789,237; passenger cars 14, valued at \$110,798, and car parts \$1,828,373. Car wheels and axles to the amount of \$756,027 were exported during the month, compared with \$593,394 in April.

At a meeting recently of representatives of all German railroad employees, with the exception of the Bavarians, it was decided to found a union of all employees. Already 350,000 members belong to this new organization. The resolution giving the board of directors the power to proclaim general strike in case of need is of special importance. Instead of sixty and more professional unions which are in existence now, the statutes of the new union allow for only nine professional organizations.

A home for boys who are taking courses in training in the apprentice department and live out of town has been started by the Brown & Sharpe Manufacturing Company, Providence, R. I. It is known as the Apprentice House and consists of a well-built three-story house located in a good residential section of Providence, a short distance from the works of the company and provides accommodation for 27 boys. It is the policy to maintain a thoroughly homelike atmosphere and to avoid any of the institutional tendencies often found in places of this kind. The house is provided with modern improvements in every way and is furnished with an aim toward comfort and a homelike environment.

The American Locomotive Company has perfected arrangements for teaching its alien employees the English language and for inducing such employees to become familiar with American ideals and to become citizens. Following the plans in effect in several other industrial plants, the classes in English for the men will take place afternoons, directly after working hours. Competent instructors will be placed in charge. The method of teaching will be similar to that employed in the General Electric Company, without using any foreign language and not using interpreters. Foundations for the language are laid in simple English phrases which the men encounter in their work every day. In one day seven men took the first steps toward citizenship.

The Western Electric Company has arranged with Columbia University, New York City, for post graduate courses for the technical men in its employ. The courses are limited to the members of the engineering department, where more than 3,000 technical men are eligible to take advantage of the offer. The hours of work in the engineering department have been especially arranged to provide those who attend the classes full opportunity for study. After the candidates are nominated by the officers of their department they must meet the academic qualifications of the University. A special course of training in technical work has also been started by the company, to instruct graduates of non-engineering colleges. The entire course takes nine months. Outside reading and lectures are required during that period.

A piston valve of the air pump of the Westinghouse brake on an English engine broke recently, says the Engineer, London. The locomotive was coupled to a passenger train, and when the fracture was discovered the driver had four miles to run, one stop to make, and the important junctions approaching the central station to be run through, and the stop in the station to be made. Besides the one stop the train had to be checked thrice and each of these occasions reduced the pressure. The train would probably have arrived safely, but at the last moment the driver thought he would not stop in time. He therefore reversed his engine, but this caused the engine wheels to lock and the train consequently ran into the buffers. Thanks to the hydraulic buffers, there was no material damage and little personal injury.

Winners in the Prize Story Contest

As the judges in the prize story contest felt that the relative merits of the stories could not be judged with fairness until after all had been published, their decision was reserved until this time. The last story was published in the July issue. Each of the judges has rated all the stories submitted.

The first prize of \$75 has been awarded to Hugh K. Christie, whose story, *Fools Rush in Where Angels Fear to Tread*, appeared in the February issue. The second prize of \$50 was won by E. F. Jones, author of the story in the June issue, *How the Master Mechanic Increased Production*. Andrew J. Fenton received the third prize of \$25 for his story, *How Jim Dugan Finally Won a "Real" Job*, published in the January issue.

Co-Operative Course in Electrical Engineering

For the past year an interesting experiment in co-operative engineering education has been conducted by the Massachusetts Institute of Technology and the General Electric Company and several departures from the usual plan which were introduced have shown decided results. The class was limited to 30 students, who were chosen entirely on the records which they had made in the equivalent of the first two years' work of the electrical engineering course at Technology. The year is divided into four three-month

periods, the students spending alternately 13 weeks at the Lynn works of the General Electric Company and 11 weeks at the Institute, followed by a two weeks' vacation. The group at Lynn is housed together in a residence which has been converted into a modern club house. No break is made in the major studies when the students are at Lynn, courses being conducted at the works in principles of electrical engineering and in general studies. The progress of the students through the plant is regulated, not by the production needs of the various departments, but by the advantage which the experience in each department is to the student. As evidence of its approval of the work, the company has increased the number of men who can be enrolled in this year's class to 60 and has already secured a new club house in order to furnish rooming accommodations for them.

MEETINGS AND CONVENTIONS

Chief Interchange Car Inspectors' and Car Foremen's Association.—The annual convention of this association will be held at the Windsor Hotel, Montreal, Que., September 14 to 16, inclusive.

The following list gives names of secretaries, dates of next or regular meetings and places of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.—J. P. Murphy, N. Y. C., Collinwood, Ohio.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. B. Baker, Terminal Railroad, St. Louis, Mo.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, 1145 E. Marquette Road, Chicago. Convention September 1-3, Hotel Sherman, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreuccetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
- CANADIAN RAILWAY CLUB.—W. A. Booth, 131 Charron St., Montreal, Que. Meetings second Tuesday in month, except June, July and August.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 North Pine Ave., Chicago. Meetings second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koeneke, secretary, Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings second Friday in January, March, May and September and second Thursday in November, Hotel Statler, Buffalo, N. Y.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—J. C. Keene, Decatur, Ill. Convention, September 14-16, Windsor Hotel, Montreal, Que.
- CINCINNATI RAILWAY CLUB.—H. Boutet, 101 Carew Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—A. L. Woodworth, B. & O., Lima, O. Convention August 17-19, Hotel Statler, Detroit, Mich.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 702 East 51st St., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention Sept. 7-10, 1920, Hotel Sherman, Chicago.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.
- MASTER CAR AND LOCOMOTIVE PAINTERS' ASSOCIATION OF U. S. AND CANADA.—A. P. Dane, B & M., Reading, Mass. Convention September 14-16, New American House, Boston, Mass.
- NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Meetings second Tuesday in month, except June, July, August and September.
- NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings third Friday in month, except June, July and August, 29 W. 39th St., New York.
- NIAGARA FRONTIER CAR MENS' ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings second Thursday in month, alternately in San Francisco and Oakland.
- RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Friday in month, except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.—J. B. Frauenthal, Union Station, St. Louis, Mo. Meetings second Friday in month, except June, July and August.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y. Convention September 14, Chicago.
- WESTERN RAILWAY CLUB.—J. M. Byrne, 916 West 78th St., Chicago. Meetings third Monday in month, except June, July and August.

PERSONAL MENTION

GENERAL

NORMAN W. ROSE has been appointed electrical engineer of the Duluth & Iron Range, succeeding A. M. Frazee.

ROBERT MCGRAW has been appointed fuel instructor on the New York Central, with headquarters at Syracuse, N. Y.

ELMER R. LARSON, supervisor of apprentices on the Delaware, Lackawanna & Western, has been appointed special motive power inspector.

A. T. PFEIFFER has been appointed assistant superintendent of fuel and locomotive performance on the New York Central, with headquarters at New York.

J. C. BRENNAN has been appointed supervisor of fuel and locomotive performance for the first district of the New York Central, with headquarters at Utica, N. Y.

E. C. ANDERSON, acting mechanical engineer of the Chicago, Burlington & Quincy, with headquarters at Chicago, has been appointed mechanical engineer, succeeding C. B. Young.

A. B. CORBETT, division master mechanic of the Missouri, Kansas & Texas of Texas, at Denison, has been transferred in the same capacity to Greenville, Tex., succeeding H. Honaker.

C. W. WHEELER has been appointed supervisor of fuel and locomotive performance for the second district of the New York Central, with headquarters at Syracuse, N. Y., succeeding L. F. Burns.

A. J. FRIES, assistant superintendent motive power of the second district, New York Central, with headquarters at Depew, N. Y., has had his title changed to district superintendent of motive power.

J. F. HILL, master mechanic of the Wheeling & Lake Erie at Brewster, Ohio, has been promoted to superintendent of motive power and cars with the same headquarters, succeeding George Durham, resigned.

R. J. NEEDHAM, mechanical and electrical engineer on the Grand Trunk, has been appointed assistant to the general superintendent of the motive power and car departments, with headquarters at Montreal, Que.

L. F. BURNS, district supervisor of fuel economy of the New York Central at Rochester, N. Y., has been appointed master mechanic of the Syracuse division, with headquarters at East Buffalo, succeeding M. W. Hassett.

W. P. DAVIS, master mechanic of the Harlem division of the New York Central, with headquarters at Brewster, N. Y., has been transferred to the Mohawk division, with headquarters at West Albany, succeeding C. F. Parsons.

H. WANAMAKER, superintendent of shops of the New York Central at West Albany, N. Y., has been appointed district superintendent of motive power of the first district, succeeding C. H. Hogan, with headquarters at Albany.

C. H. HOGAN, district superintendent of motive power, first district, of the New York Central, with headquarters at Albany, N. Y., has been promoted to manager of the department of shop labor, with headquarters at Buffalo, N. Y.

F. S. GALLAGHER, assistant engineer in the general mechanical engineer's office of the New York Central, has been appointed engineer of rolling stock with office in New York, under B. B. Milner, engineer of rolling stock and motive

power. Mr. Gallagher was born at Tecumseh, Mich., and began railroad work as a machinist apprentice. He was later employed by the Pullman Company and the Lake Shore & Michigan Southern as a draftsman, leaving the latter road to come with the New York Central as assistant engineer in the general mechanical engineer's office.

J. W. CHANDLER, district foreman on the Poteau Valley line of the Kansas City Southern, with headquarters at Heavener, Okla., has been promoted to master mechanic, with headquarters at Shreveport, La., succeeding A. D. Williams.

R. W. ANDERSON, assistant superintendent motive power of the Chicago, Milwaukee & St. Paul, Lines East, with headquarters at Milwaukee, Wis., has been appointed superintendent motive power with the same headquarters. Mr. Anderson was born on May 6, 1877, in Madison county, Iowa. He began railroad work in January, 1892, as a machinist apprentice for the Des Moines Union. In January, 1897, he went to the Chicago, Rock Island & Pacific as machinist and retained that position until May, 1903, when he was promoted to assistant roundhouse foreman. Some months later he became roundhouse foreman. He entered the employ of the Chicago, Milwaukee & St. Paul as machinist at Mitchell, S. D., in September, 1904, and in November, 1905, was appointed assistant roundhouse foreman at the same place. He was transferred as machinist to the Idaho division in September, 1907, and in June of the following year was promoted to mechanical foreman of the same division. From May, 1908, until August, 1911, he served as roundhouse foreman at Avery, Idaho. He was then transferred to Miles City, Mont., and while there was appointed district master mechanic in November, 1912. He retained that position until June, 1918, when he was promoted to assistant superintendent motive power, as mentioned above.

R. W. Anderson

C. B. YOUNG, who was recently reappointed mechanical engineer of the Chicago, Burlington & Quincy, with headquarters at Chicago, as noted in these columns last month, has been promoted to general mechanical engineer, with the same headquarters.

L. K. SILLCOX, recently appointed assistant general superintendent motive power of the Chicago, Milwaukee & St. Paul, has now been appointed general superintendent motive power, with headquarters at Milwaukee, Wis., succeeding H. R. Warnock.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

J. H. HENLEY, master mechanic of the Missouri, Kansas & Texas at Parsons, Kan., has been appointed road foreman of engines and will have his headquarters at Muskogee, Okla.

C. F. PARSONS, master mechanic of the New York Central at West Albany, N. Y., has been appointed general master mechanic of the first district, with headquarters at Albany.

A. D. WILLIAMS has been appointed master mechanic of the Texarkana & Fort Smith, with headquarters at Texarkana, Tex., succeeding F. M. Hill assigned to other duties.

M. W. HASSETT, master mechanic of the New York Central at East Buffalo, N. Y., has been appointed general master mechanic of the second district, with the same headquarters.

W. H. ECKROATE, road foreman of engines of the Wheeling & Lake Erie at Brewster, Ohio, has been appointed master mechanic, succeeding J. F. Hill, with the same headquarters.

J. J. MELLEY, master mechanic of the Missouri, Kansas & Texas, of Texas, at Wichita Falls, Tex., has been transferred to Parsons, Kan., succeeding J. H. Henley as master mechanic there.

A. J. LEWIS, shop superintendent of the Missouri, Kansas & Texas of Texas, at Denison, has been appointed division master mechanic, with the same headquarters, succeeding A. B. Corbett.

H. HONAKER, master mechanic of the Missouri, Kansas & Texas of Texas, with headquarters at Greenville, Tex., has been transferred in the same capacity to Wichita Falls, Tex., succeeding J. J. Melley.

A. T. HEINTZ, assistant master mechanic of the Mohawk division of the New York Central at West Albany, N. Y. has been appointed master mechanic of the Harlem division, with headquarters at Brewster, N. Y., succeeding W. P. Davis.

CAR DEPARTMENT

J. H. DOUGLAS, general shop foreman of the Wheeling & Lake Erie at Ironville, Ohio, has been promoted to master car builder, with headquarters at Brewster, Ohio.

A. J. WILLIAMS, assistant road foreman of engines on the Maryland division of the Pennsylvania, has been appointed general air brake and steam heat inspector on the Southern division.

CHARLES I. WALKER, whose promotion to master car repairer of the Southern Pacific, with headquarters at Los Angeles, Cal., was announced in these columns last month, was born on December 3, 1875, at Hillsboro, Mo. Mr. Walker entered railway service as an apprentice car builder with the St. Louis, Iron Mountain & Southern on July 27, 1891, and during the next seven years served in several branches of this department. In June, 1898, he entered the service of the Mexican National, with headquarters at Laredo, Tex., as a car builder. In September, 1898, he went with the St. Charles Car Company at St. Charles, Mo., and in August, 1900, with the Pullman Company at Chicago, where he was later promoted to assistant foreman. In July, 1904, he returned to the Mexican National at Laredo, and on February 1, 1905, he was promoted to master car builder on that system. He was appointed foreman in the passenger repair department of the Cincinnati, Hamilton & Dayton, with headquarters at Lima, O., in July, 1906. In October 1907, he became a shop foreman on the Southern Pacific, and shortly thereafter was appointed draftsman. After a short service as inspector, he was transferred, in May, 1919, to the general freight car department at San Francisco, Cal., where he was located at the time of his recent promotion.

SHOP AND ENGINEHOUSE

D. JOHNSON has been appointed general foreman of the Erie at Marion, Ohio, succeeding R. M. Wilson, transferred.

H. SCHMIDT has been appointed roundhouse foreman of the Erie at Cleveland, Ohio, succeeding F. C. Hunter, transferred.

J. B. FRASER has been appointed shop foreman of the Canadian National at Saskatoon, Sask., succeeding A. D. McMillan, resigned.

B. C. NICHOLSON has been appointed shop superintendent at Denison, Tex., of the Missouri, Kansas & Texas of Texas, succeeding A. J. Lewis.

S. J. DILLON, enginehouse foreman of the Pennsylvania at Atlantic City, N. J., has been appointed shop inspector on the New Jersey division.

ENOCH HEWITT, general foreman of the Pennsylvania shops at Meadows, N. J., has been appointed enginehouse foreman at Atlantic City, succeeding S. J. Dillon.

JOHN MURRAY, assistant supervisor of apprentices on the Delaware, Lackawanna & Western, has been promoted to supervisor of apprentices, succeeding Elmer R. Larson.

J. G. PARSONS, superintendent of shops of the New York Central at Depew, N. Y., has been transferred to West Albany as superintendent of shops, succeeding H. Wanamaker.

J. C. LAPORT, enginehouse foreman of the Pennsylvania at Coalport, has been appointed general foreman of the Meadows shops, Meadows, N. J., succeeding Enoch Hewitt.

B. F. SHONE, general foreman of the locomotive department of the New York Central at Depew, N. Y., has been appointed superintendent of shops there, succeeding J. G. Parsons.

PURCHASING AND STOREKEEPING

DANIEL W. ROBERTS, division storekeeper of the Union Pacific at Kansas City, Mo., has been appointed general storekeeper of the Pere Marquette, with headquarters at Detroit, Mich.

D. W. Roberts

Mr. Roberts was in the service of the Union Pacific continuously since 1906, having entered the employ of that road as a call boy at Cheyenne, Wyo. In 1909 he was appointed storekeeper at Cheyenne, being transferred to Omaha, Neb., in 1911 and to North Platte, Neb., in 1913. In 1915 he returned to Cheyenne as division storekeeper and in 1917 went to Denver, Colo., in the same capacity. He was transferred to Kansas City in 1918, and held the position

of division storekeeper there until he recently resigned it to accept his present one as general storekeeper of the Pere Marquette.

E. H. HUGHES has been appointed general storekeeper of the Kansas City Southern, with headquarters at Pittsburgh, Kans., succeeding R. C. Lowry, resigned.

OBITUARY

BENJAMIN F. SARVER, boilermaker foreman of the Pennsylvania at Fort Wayne, Ind., died of heart disease on July 23 at a hospital in Chicago. Mr. Sarver was a member of the executive board of the Master Boiler Makers' Association and was one of its earliest members.

SUPPLY TRADE NOTES

James L. Gough, president of the Federal Machinery Sales Company, Chicago, has retired from active business.

Frank J. Farrell has been appointed eastern representative of the Precision & Thread Grinder Manufacturing Company, Philadelphia, Pa.

Clark T. Dickerman, sales agent for the American Car & Foundry Company, with headquarters at New York, has been transferred to the Chicago office.

B. M. Jones & Co., Inc., New York, distributors for Double Mushet high speed steel and Taylor's Best Yorkshire iron, announce that they are now being represented in the southeastern territory by the W. S. Murrian Company, 605 Fourth street, Knoxville, Tenn. W. S. Murrian for a number of years was connected with the mechanical department of the Southern Railway, but during the war period he was associated with the United States Railroad Administration, Railway Board of Adjustment No. 2. His son, John H. Murrian, has recently been discharged from the army, having served with the American Overseas Air Force and being the possessor of three distinguished foreign decorations.

W. S. Murrian

G. M. Calmbach, welding supervisor of the Kansas City Southern, has been appointed welding advisory engineer of the Geist Manufacturing Company, Atlantic City, N. J.

Roland Whitehurst, of the New York sales office of the Electric Storage Battery Company, Philadelphia, Pa., has been appointed manager of the Washington, D. C., sales office.

T. W. McManus, master mechanic for the Kellogg Switchboard & Supply Company, Chicago, has been elected vice-president and general manager of the Security Tool Works, Chicago.

W. W. Rosser, vice-president of the T. H. Symington Company, Rochester, N. Y., has become associated with the Bradford Draft Gear Company, New York, with headquarters at Chicago.

W. L. Randall and T. D. Randall of D. W. Randall & Co., Chicago, have recently organized the Randall Foundry and will build a plant at Michigan City, Ind., for the manufacture of grey iron castings for railway equipment.

The Halcomb Steel Company, Syracuse, N. Y., announces the opening of a branch office and warehouse with a complete stock of the company's tool steel products. The New York office will be under the management of F. W. Ross.

The Electric Controller & Manufacturing Company, Cleveland, Ohio, has opened a new office in Philadelphia, in charge of H. K. Hardcastle. It is located in the Wither- spoon building, at the corner of Walnut and Juniper streets.

W. S. Quigley, president of the Quigley Furnace Specialties Company, New York, recently sailed for Europe for the purpose of furthering the business relations of the Quigley organization in England, France, Belgium, Italy and Spain.

The Refinite Company, Omaha, Neb., manufacturer of the Refinite water softener and the Refinite rapid pressure filter, has just acquired ownership and control of the L. M. Booth Company, Jersey City, N. J., manufacturer of the Booth limesoda water softener.

The Air Reduction Sales Company has just completed the construction of a new acetylene plant at 560 Broadway, Gloucester, N. J. The buildings making up this new unit consist of a gas house, carbide storage building and a generator house.

The American Car & Foundry Company has recently purchased two additional pieces of real estate for its contemplated \$2,000,000 plant extending from Blue Island avenue, along Paulina street to the Chicago river, at Chicago. The land, now occupied by the company, was formerly under lease.

The general offices of the Wilson Welder & Metals Company, formerly at 2 Rector street, New York, have been moved to 253 Thirty-sixth street, Bush Terminal, Brooklyn, N. Y. The offices of the Wilson Welding Repair Company, formerly of the same address, are now at 263 First street, Jersey City, N. J.

Simon M. Dolan has been elected vice-president of the G. F. Cotter Supply Company, Houston, Tex. He began railway work with the Baltimore & Ohio as a boilermaker apprentice at Garrett, Ind. Two years later he was made a machinist apprentice, and subsequently served on various railroads and in industries as a machinist and for a short time as a locomotive fireman. From 1894 to 1902, he was with the Wiggins Ferry Company, St. Louis, consecutively as general foreman, master mechanic and superintendent, and also served as master mechanic on other railroads. He subsequently went to the

S. M. Dolan

Southern Railway as general mechanical inspector, and later was master mechanic. In 1905 he went to the Missouri Pacific as a master mechanic at Little Rock, Ark., and later served in the shops at Sedalia, Mo. In 1908 he entered the service of the Scullin Steel Company in its steel plant and later was sales agent and assistant to the vice-president in charge of sales, respectively. He was sales agent for the American Car & Foundry Company, St. Louis, in 1911, and four years later went with the Chicago Varnish Company, resigning recently from the position of western and southwestern representative of its railroad department to become vice-president of the G. F. Cotter Supply Company.

Alfred Herbert, Ltd., machine tool makers and importers, Coventry, England, announce that E. D. Mitchell, for many years a member of the Coventry staff, and lately assistant manager of the New York branch, has been appointed man-

ager at New York, to succeed W. J. Fuller, who has resigned from that position.

B. B. Milner, now engineer of motive power and rolling stock of New York Central, has completed arrangements for becoming associated with the Oriental organization of Frazar & Co., 30 Church street, New York, and will sail for his new headquarters in the Tokio, Japan, offices of Sale & Frazar, Ltd., some time this fall.

The New York Air Brake Company, New York, has opened an office in room 1405, Walker Bank building, Salt Lake City, Utah, which will be the headquarters for Captain Thomas O'Leary, Jr., representative. Captain O'Leary has acted as representative of the company in western territory since his return from France.

F. V. Green, who left the service of the Westinghouse Air Brake Company some time ago to become associated with the Baldwin Locomotive Works, has now opened his office in the Standard Bank building, Johannesburg, South Africa. Mr. Green is export manager for the Baldwin Locomotive Works, in charge of South African territory.

Albert G. Elvin, who has been elected vice-president in charge of operation and treasurer of the Elvin Mechanical Stoker Company, New York, as was announced in the July

A. G. Elvin

issue, was born on February 26, 1865, at North Vernon, Ind., and was educated in the public schools. He began railway work in 1881, serving as boiler-maker and machinist apprentice at Peru, Ind., on the Indianapolis, Peru & Chicago. In 1889 he went to the Pittsburgh, Cincinnati, Chicago & St. Louis at Indianapolis as a machinist and in 1890, was put in charge of the tool shop, manufacturing all tools for the entire system. He was later general foreman on the Chesapeake & Ohio at Clifton Forge, Va., master mechanic on the Grand Trunk, Montreal, Que., and in January, 1901, he was appointed general master mechanic on the Delaware, Lackawanna & Western at Scranton, Pa. During this time he designed and put into operation many labor-saving devices. Among these, in 1896, he introduced the first pneumatically operated turntables and transfer tables in this country. In 1902 he invented and patented the Elvin driving box lubricator, which is known today as the Franklin driving box lubricator and has been standard on the majority of locomotives in the United States and Canada for the past 14 years. In 1903 he went to the Franklin Railway Supply Company, then known as the Coffin-Megeath Supply Company, and remained with the company as mechanical manager until 1916, when he retired from active work due to a breakdown in health. During the time he was associated with the Franklin Railway Supply Company he invented and patented a pneumatic fire-door, and the steam grate shaker. The latest of his devices is the Elvin mechanical stoker, which has been in successful service for the past three years on the Erie Railroad.

The Falls Hollow Staybolt Company, Cuyahoga Falls, Ohio, announces that the Minnesota Supply Company, 802 Pioneer building, St. Paul, Minn., has been appointed its

northwest sales representative. The business is in charge of W. H. Hooper, who has been engaged in railway work and the railway supply field for the past 25 years.

The extensive improvements contemplated by the Pollak Steel Company, Cincinnati, Ohio, for its rolling mill at Marion, Ohio, some time ago, are now in the course of actual construction. The improvements consist of several new buildings, equipment, etc. The products of this plant consist of rolled steel bars and shapes, concrete reinforcing bars, etc.

The Clark-Mesker Company, Cleveland, Ohio, was recently incorporated for the purpose of taking over the machine tool department of the Cleveland Milling Machine Company. The officers of the new company are as follows: D. B. Clark, president; L. H. Mesker, vice-president and general manager, and Charles A. Morris, secretary and treasurer.

The Imperial Japanese government has conferred the Fourth Class of the Imperial Order of Mediji upon Charles M. Muchnic, vice-president of the American Locomotive Sales Corporation, New York, and invested him with the insignia of the Imperial Order of the Rising Sun pertaining to said class, in expression of the good will which it entertains towards him.

R. T. Hazelton has been appointed works manager, in complete charge of production, of the Cincinnati Shaper Company, Cincinnati, Ohio, and will also act in this capacity for the Cincinnati Gear Cutting Machine Company, a subsidiary of the Cincinnati Shaper Company. Mr. Hazelton was formerly superintendent and chief engineer of the Cincinnati Milling Machine Company.

The Burden Iron Company, Troy, N. Y., has entered into a contract for a term of years with the Burden Iron Company Railroad and Steamship Division, to dispose of its products as applied to railroad and steamship companies. Edward L. Smith is the general partner of this newly organized partnership, and W. J. Caton has been appointed secretary, with office at 3711 Grand Central Terminal, New York.

The Worthington Pump & Machinery Corporation, New York, announces the purchase from the Platt Iron Works, Dayton, Ohio, of its drawings, patterns, jigs, templates, special tools, good-will and name, on its following lines of product: Oil mill machinery, hydraulic turbines and water wheels, feed water heaters and high pressure air compressors for torpedo and other high pressure charging, cleaning and discharging.

T. D. Slingman has joined the sales organization of the Keller Pneumatic Tool Company, Grand Haven, Mich., as special representative, with headquarters at its Pittsburgh office. Mr. Slingman has for many years been identified with the selling organization of the Chicago Pneumatic Tool Company, for the past nine years as district manager at Detroit. He left the service of that company on June 1 and shortly thereafter joined the Keller force.

The drop forging business and plants of the Whitman & Barnes Manufacturing Company at Chicago and St. Catharines, Ont., have been combined with the J. H. Williams & Co., Brooklyn, and will be operated by this company. The organization will include the individuals heretofore identified with both businesses. The business of the Whitman & Barnes Manufacturing Company, Akron, Ohio, will be confined to the manufacture of twist drills and reamers.

Edward A. Schreiber, general manager of the Vapor Car Heating Company, Railway Exchange building, Chicago, died on July 4 from heart trouble, following a previous at-

tack on May 20, just after his return from a European trip in the interest of the car heating company. Mr. Schreiber was formerly connected with the steam fitting department at the Pullman car works, and in 1901, entered the service of the Chicago Car Heating Company, predecessor of the present Vapor Car Heating Company, since which time, and up to his death at the age of 58, he was active in the affairs of that company.

L. E. Summers has been appointed works manager of the Keller Pneumatic Tool Company's factory at Grand Haven, Mich. Mr. Summers is one of the pioneers in the mechanical department of the pneumatic tool industry, having started his career in 1894 with Joseph Boyer, St. Louis. He then went to the Boyer plant of the Chicago Pneumatic Tool Company, at Detroit, where he was assistant manager for nine years, and then he was works manager for eight years. He resigned in 1918, since which time he has been employed by various interests on the Pacific Coast, until he joined the Keller organization on June 1 of this year.

The Milwaukee Electric Railway & Light Company, after more than two years of continued use of pulverized coal under five boilers in the Oneida street plant, has decided to use this form of fuel in the new Lakeside power plant. The installation will consist of eight 1,306-hp. Edgemoor water tube boilers. The contract for the drying, pulverizing and transportation equipment has been placed with the Fuller Engineering Company, Allentown, Pa. The feeders and burners will be furnished by the Locomotive Pulverized Fuel Company, New York. Lopulco duplex feeders with five-inch screws will be used and three Lopulco burners will be installed in each boiler. The feeders will be driven by Morse silent chain and the Reeves type variable speed mechanism.

Charles P. King, formerly manager of the New York office of the Lima Locomotive Works, Inc., and who for several years previously traveled in the West Indies and Central and South American countries for the same corporation, on July 15 assumed charge of the car business of the Ralston Steel Car Company, Columbus, Ohio, as eastern sales and export representative at the offices of the Ralston Car Sales Corporation, the selling agent for the Ralston Steel Car Company, 2 Rector street, New York. Mr. King received his preliminary training in the car building business in the shops and offices of the old Jackson & Sharp Car Company, Wilmington, Del., under the direction of his father, A. M. King, who was, for many years, until his death in 1897, general superintendent of that company. Mr. King returns to the railroad field after a brief venture in the export trade-paper publishing business.

Harry R. Warnock, general superintendent of motive power of the Chicago, Milwaukee & St. Paul, has become associated with the Standard Stoker Company, New York, as vice-president in charge of the mechanical department, with headquarters at New York. Mr. Warnock was born at Newcastle, Pa., on July 16, 1870. He began railway work as a freight brakeman with the Pennsylvania Lines West of Pittsburgh in June, 1889. He later worked as a brakeman, locomotive fireman and engineman on the Pittsburgh & Lake Erie until May, 1900. From that date until July, 1904, he served consecutively as engine dispatcher, roundhouse foreman, and general foreman, resigning from that position to become master mechanic of the West Side Belt, Pittsburgh, Pa., where he remained until October, 1905, when he became master mechanic of the Monongahela Railroad. He remained in this position until September, 1913, when he was appointed superintendent of motive power of the Western Maryland, and on December 15, 1917, was appointed general superintendent of motive power of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago.

TRADE PUBLICATIONS

OIL SEPARATOR.—The Griscom-Russell Company, New York, describes the construction of the Bundy oil separator in a 12-page bulletin, No. 1130. This separator is designed for the removal of oil from exhaust steam in power plants. Sectional views and drawings make the construction and operation clear and instructions are given for cleaning.

TWIST DRILLS AND REAMERS.—The Whitman & Barnes Manufacturing Company, Akron, Ohio, which is now manufacturing twist drills and reamers exclusively, has revised its catalogue to cover only these products. It contains 120 pages, giving prices and all necessary data. In the back of the book are tables of tap drill sizes, decimal equivalents of regular sizes, cutting feeds and speeds, etc.

PNEUMATIC TOOLS AND ELECTRIC DRILLS.—The Independent Pneumatic Tool Company, Chicago, has revised its catalogue of Thor tools. The new book contains 78 pages, giving descriptions, illustrations, dimensions and sizes, and covers the new additions to the line, consisting of motor driven air hoists, pneumatic sand rammers, universal vise for pneumatic drills, hose coupling, power screw driver, hose clamp and hose mender.

FEEDWATER HEATING.—Figures showing the amounts that may be saved on coal bills by preheating feedwater with the heater developed by the Locomotive Feed Water Heater Company, New York, are contained in bulletin No. 6, issued by that company. The savings are also presented graphically on a chart which is arranged to show the monthly saving per locomotive for any combination of fuel consumption and gross ton miles per month and for varying coal costs.

AUTOMATIC TRAIN LINE CONNECTORS.—The Robinson Connector Company, New York, has recently issued a 23 page booklet illustrating the advantages and method of operation of the Robinson connector. Attention is called to the simplicity of the connector and its automatic features. Clear cut illustrations show how the connector is applied to the draw bar and a view is shown of the shop in which connector parts are made. The booklet is well illustrated and carefully written.

DRIVING BOX WEDGE.—The operation and construction of the Franklin automatic adjustable driving box wedge, which is claimed to maintain wedge adjustment under all conditions and increase the life of crown bearings and rod bushings, is described fully in a four-page pamphlet, bulletin No. 601, distributed by the Franklin Railway Supply Company, New York. Instructions are also given for applying the wedge on new and existing power and a drawing is included showing its proportions and the space that should be provided for wedges when designing new engines.

DIE HEADS.—The Eastern Machine Screw Corporation, New Haven, Conn., has compiled a 96-page catalogue covering H & G automatic self-opening die heads and collapsible taps, and in addition includes much valuable data relating to thread cutting that should be useful to men working out threading problems. The descriptions are concise and are well illustrated. They cover four types of die heads, a new H & G collapsible tap and chasers for the die heads. Detailed instructions for opening the heads, installing chasers, closing the heads and adjusting the pitch diameter, with information on cutting speeds and lubricants, is also included.

Railway Mechanical Engineer

VOLUME 94, NUMBER 9.

New York—SEPTEMBER, 1920—Chicago

ESTABLISHED IN 1832

At the End of the Rainbow—

There used to be, and perhaps is now among some people, a belief that at the end of the rainbow would be found a pot of gold.

Applied to the practical features of railroading, many roads have found a fairly good showing of the yellow metal by following a less elusive guide.

Hutchins All-Steel Flexible Car Roofs

indicate where money may be found in the saving of labor in car repairs, in the reduction of damage claims on lading, in the reduction of the weight of the car and in the greater security and capacity which they add to the whole car.

Advance In Subscription Rates

TO OUR READERS:

The subscription rate to the *Railway Mechanical Engineer* on the basis of the number of editorial pages is the same today as it was a quarter of a century or more ago; this with the exception of an increase which was recently made to readers west of the Mississippi river, caused by the establishment of the excessive zone postal charges. Hereafter the subscription rate throughout the United States, Canada and Mexico will be \$4. The rate to subscribers in other countries will be \$5, and the price of a single copy will be 50 cents.

The publishing business, like the railroad and all other businesses, has been subjected to large increases in its costs of production. There are, however, special influences affecting the publishing business about which we feel our readers should be told. The white paper used by newspapers and periodicals, for instance, constitutes one of the largest items in their cost of production. During the first six months of the year 1920 the expenditures for paper for the *Railway Mechanical Engineer* and the other railway papers published by the Simmons-Boardman Publishing Company were 104 per cent greater than in the first six months of 1919. This increase in cost was due only in a small degree to an increase in the amount of paper used. It was caused largely by advances in the prices that we have had to pay.

Even if the advance in the price of paper was the only advance in cost that we had to meet, it would be serious; but it by no means stands alone. During the first six months of 1920 the expense of typesetting, press work, binding and

bulk postage of our railway papers was 125 per cent greater than in 1919. During the same period the increase in the cost of the engravings used as illustrations in our editorial pages was 265 per cent.

These statistics indicate the increases which have occurred in our "manufacturing costs." We have also been affected by the same influences which have compelled business concerns of all kinds to increase the wages and salaries of their employees. Publications of all kinds, owing to similar developments have been forced to advance their subscription rates. Metropolitan newspapers which formerly sold for one cent are now being sold for two and even three cents.

We are deeply appreciative of the loyal support which we have always received from our readers. It will be our endeavor in the future, as it has been in the past, constantly to make the *Railway Mechanical Engineer* a better paper, and we bespeak your continued cordial co-operation.

ROY V. WRIGHT,

Editor.

It was once remarked by an able railroad executive that the successful railroad man was one who knew something about every branch of railroading and everything about one department. This is unquestionably true and the fact is doubtless appreciated by many young men in railroad service. Is it not probable, however, that some of these young men are laboring under the impression that a general knowledge of each department is of the first importance and that the obvious

**The All-Round
Railroad
Man**

way in which to acquire an all-around knowledge of railway operation is to seek employment in various branches of the service by switching from one department to another as often as the opportunity presents itself? What the diversified tendency undertaken under a misguided notion may result in is well illustrated in the following reply recently received to an advertisement for a man having a good knowledge of railroading with some experience in the mechanical department: "I am an all-round railroad man experienced in all branches, viz, conductor, brakeman, fireman, engineer, track foreman, yard master, train master, despatcher, master mechanic, superintendent, maintenance of way, accountant, paymaster and detective." While the applicant further states that he can do anything desired, his proficiency in any line whatever would, of course, be seriously questioned. It would be well to bear in mind the fact that while executives have usually a surprisingly intimate knowledge of the conduct of every department, they have generally acquired this through keen observation and study in preference to the process of rotating from one department to another, which is often more demoralizing than helpful. Success depends so largely upon the tangible value of your services to your superior officers that a very thorough knowledge of just one feature may be put down as the most important single qualification.

The railroads are bending their energies to getting the maximum mileage from all freight equipment. While the immediate necessity for more transportation justifies any measures that can be taken to meet the situation, the consequences may be serious unless the needs of the future are considered. There

Permanent Improvements to Cars

is no prospect that the amount of freight which the railroads are called on to handle will decrease. Cars which make unusually high mileage are sure to wear out with unusual rapidity and precautions must be taken to prevent cars being kept in service when in need of extensive repairs lest the roads find themselves at some future date handicapped by a large amount of freight equipment in a deteriorated condition.

The obvious remedy for this condition would be the immediate purchase of large amounts of new equipment, but with the present serious shortage of freight cars the existing equipment must be kept in service whether or not new cars are acquired.

While some roads have such a large proportion of bad order cars that no heavy repairs can be made with the existing forces and facilities, the roads that have reduced the bad order equipment to a reasonable percentage should put in effect a program for the reinforcing of equipment. This work should have for its object the elimination of all the troublesome defects that have developed in service. Not only should steel center sills or metal draft arms be applied where necessary, but the cars should be equipped with thicker end lining and steel end and corner posts or all steel ends. Roofs of substantial construction should be applied and the superstructure should be reinforced when necessary to avoid distorting the roof sheets. Side doors with steel frames and adequate door fixtures will eliminate many a damage claim and many a trip to the repair track. The trucks should not be overlooked; safety hangers for the brake beams should be applied where needed; side bars should receive attention; the weak truck bolsters should be replaced. The reduction of bad order cars to a maximum of 4 per cent is a praiseworthy object, but the emergency is not great enough to justify any road in meeting the situation by disregarding sound policies in the current maintainance of its car equipment.

The fact that transportation is a limiting factor in the output of some of America's important industries has been stressed so often that it hardly needs emphasis. The difficulties of the early months of this year caused a falling off in the traffic handled, but with normal conditions restored the roads have been steadily increasing the amount of freight hauled. During the week of August 14, the number of cars loaded was 962,352, an increase of 129,913 cars over the corresponding week of 1919, and of 13,556 cars over the corresponding week of 1918. This is a new high record for this season of the year.

Breaking Transportation Records

In order to better this, if possible, the Association of Railway Executives has set as a definite goal the following performance: 1—An average daily minimum movement of freight cars of not less than 30 miles per day; 2—An average loading of 30 tons per car; 3—Reduction of bad order cars to a maximum of 4 per cent of total owned; 4—An early and substantial reduction in the number of locomotives now unfit for service; 5—More effective efforts to bring about the return of cars to the owner roads.

Of these five factors which contribute to the operating efficiency, the third and fourth are matters for which the mechanical department is directly responsible.

The number of bad order cars is still very large and every effort must be made to get the cars into service. The roads should not hesitate to seek assistance from car building plants that may have excess capital available for repair work if they cannot reduce the percentage of bad order cars with their own forces. The report of locomotives out of service for repairs shows that the motive power on some roads is in excellent condition. Other roads have a high percentage of engines awaiting classified repairs. With labor available, the roads that are hampered by lack of serviceable power should add to the forces to improve conditions before winter weather increases the amount of maintenance work.

Are micrometer calipers an unnecessary refinement for railway shop work? Is it true that railway mechanics are not

The Use of Micrometers

qualified to use any instrument more accurate than a two-foot rule? Both of these ideas have become so firmly imbedded in the minds of some people that it is difficult to dislodge them. but we feel that the correct answer to both questions is a decided "No." This belief is substantiated by the conclusions reached in an article entitled "Micrometer Calipers in Railway Shops" appearing elsewhere in this issue. The author of the article is a practical railway shop man of many years' experience, who maintains that the more general use of micrometer calipers will improve both the quality and quantity of shop output. Many important arguments are presented and detailed illustrations given to show how the use of micrometers on various classes of work will tend to produce the results predicted.

As an example of the way in which improved quality of work can be obtained the author cites the many force fits that must be made in locomotive repair work. It is pointed out that the safety of passengers and trainmen depends upon axle fits in wheel centers, which can be made most accurately when micrometer calipers are used in measuring. Some parts of locomotive motion work must be provided with running fits within certain limits. When these fits are too tight, the results are as serious as when too loose, and the exact amount of play, demonstrated by experience to be correct, can best be measured with micrometers. The use of micrometers in railway shops also makes possible more accurate measurements on many other classes of work. Mechanics can tell exactly how close they are working and

the results will be a general toning up and improvement in workmanship.

It was stated that shop output is increased in quantity, due to the fact that machine parts may be calipered more quickly with micrometers than with ordinary calipers and a scale. By having all measurements of similar work made by one man and recorded on suitable forms, machine operators can remain at their stations and thus reduce the idle machine hours. Micrometers also make possible greater accuracy in machining and therefore eliminate many scraping operations. For example, driving box brasses can be bored a limited amount larger than the journals and applied without further scraping or fitting, experience having demonstrated that no unsatisfactory results will follow. The reduction in the number of solid ring gages required, the tendency to eliminate disputes between inspectors and workmen and other important results of the use of micrometers are also pointed out in the article.

Although staggering under an appalling fuel bill, how many railroads are making a consistent and persistent effort to reduce this bill, and how many of these

Fads and Facts About Fuel

have organized this effort on the same stable basis that characterizes the conduct of other departments? How many executives regard the fuel department as a fad, how many consider it a necessity? Nowhere will organized effort count for more than when directed towards fuel conservation on our railroads. But as long as supervision is regarded as a fad, so long will it remain a failure. If the management were dissatisfied with the operating department or with the mechanical department it is possible that they would make some change, but certainly they would not dispense with the organization even if that were practical. Yet every turn in the affairs of many railroads affects the mode of fuel supervision and fuel departments come and go as regularly as the tide. The railroads must consider fuel supervision as something more than a fad, they must organize this work on a sound basis and stick by the organization if they expect to stem the rising tide of fuel costs.

NEW BOOKS

Tin, Sheet Iron and Copper Plate Worker. By Leroy I. Blinn. 5 in. by 7 in., illustrated, bound in cloth. Published by Henry Carey Baird & Co., 2 West Forty-fifth street, New York.

This book can best be classed as a reference volume for engineers, foremen and mechanics who have to do with sheet metal working of any description. It could also be made use of as a text on this subject and will afford interesting reading to anyone versed in the manipulation of sheet metals, though it is primarily a handbook designed for the guidance of workers in sheet metal. As such it is eminently practical and deals most thoroughly with every phase of this work. Particular attention is given to the rules for laying out work of all descriptions, the composition of metallic alloys and solders, recipes for varnishes, lacquers, cements and so on. All the manipulations encountered in the work shop are described quite definitely. As this book is a revised edition of an earlier publication it may be added for the benefit of those who are familiar with the previous edition that the new edition contains all the fundamental subject matter appearing in the original publication, augmented by data on the modern system of triangulation as related particularly to skylight work. Moreover, the portion of the earlier edition treating on metallic alloys and solders has been entirely rewritten so as to incorporate the best modern practice. The subjects are systematically grouped and a complete alphabetical index adds to the value of the book as a reference volume.

COMMUNICATIONS

HANDHOLDS VS. WASHOUT PLUGS

OMAHA, Nebr.

TO THE EDITOR:

Referring to the editorial Accidents Due to Washout Plugs, appearing in your January number and the articles by Mr. Lipetz and Mr. Grant in your April and June issues respectively pertaining to this subject.

The ordinary plugs in general use in this country were inherited from our very first locomotives which carried low boiler pressures and were built before the advent of the tube supported fire-box brick arches, which requires from 4 to 12 additional plugs, according to the width of the fire-box. The use of these plugs has been continued, probably due to the fact that they are simple and inexpensive in first cost, but it should be apparent to anyone familiar with the subject that they are inefficient and are not meeting modern service requirements. The final threads in the boiler sheets, being exposed when the plugs are removed, are subject to wear and damage by the insertion of the boiler washout implements. Further, the threads become clogged with dirt and scale from the boiler, resulting quite often in crossing the threads when the plugs are screwed in place.

When these plugs are located in the curved corners of the fire-box, usually not more than two full threads of the plug engage the sheets, and in order to obtain even this small number of threads the plug is limited to two inches in diameter and 12 threads per inch.

The Pennsylvania Railroad has used for a number of years, and to a considerable extent, handholds similar in general construction to those described by Mr. Lipetz, with the exception that they employ special asbestos gaskets instead of the lead gaskets. This type of handhold undoubtedly provides a more safe form of construction than the ordinary washout plug, but it is more troublesome to handle, and more costly.

Another type of construction which has been used to a limited extent in this country consists in flanging out and threading the fire-box sheets around the washout holes, and inserting the ordinary plugs, but this arrangement has practically all of the inherent defects of the ordinary plugs and the disadvantage that the sheets are materially reduced in thickness and weakened by the process of forming the flange as described.

Attention is invited to the form of washout plug illustrated by the accompanying sketch, which is self-explanatory and which was developed and patented by Messrs. Gilmore and Woodward, engineers of the American Locomotive Company.

The sketch shows the plug applied at the corner of the fire-box, but the same arrangement can be used on flat surfaces and for arch tube plugs. The square portion of the plug, provided for receiving the wrench, is shown extending outwardly, but it can be countersunk if desired into the outer end of the plug, thereby making the whole arrangement more compact.

It is understood that about 150 locomotives, built in this country, mostly for service abroad, have been equipped with these plugs, but I have no actual information as to how the plugs have met the service conditions.

With this plug the usual boiler cleaning tools could not damage the threads, nor could they become clogged with dirt from the boiler, and as relatively coarse threads could be used on the cap it is thought that little trouble should be experienced with crossed threads. It is simple in construc-

tion, should be reasonable in cost, and could be readily handled.

As accidents due to washout plugs are on the increase, and as it is generally admitted the plugs in common use are not meeting present-day conditions, the matter is of importance and it would seem that it should be given serious consideration by all concerned and especially by the committee on Design and Maintenance of Locomotive Boilers, of the American Railroad Association.

JOHN L. MOHUN,
Mechanical Asst. Union Pacific System.

FAIR PLAY FOR THE SERVICE OF SUPPLY

TO THE EDITOR:

Your editorial on the Service of Supply, appearing in the May issue of the *Railway Mechanical Engineer*, attracted my serious attention and I have read the subsequent correspondence which developed in connection with this editorial with more than usual interest.

It appears to me that in the first place much of the misunderstanding referred to between the mechanical and the stores department is in a large measure due to non-comprehension on the part of the mechanical department of the aim and purpose of the Service of Supply. This department fully appreciates that the mechanical department must have the material with which to work and it is never the purpose of the stores department to embarrass the operation of the mechanical department by restricting the supplies of material furnished to this department. The quantity of these supplies is always limited by two very important factors; the availability of the material and the financial resources of the railroad. During times such as we have been passing through, it has often been exceedingly difficult to obtain the materials which are needed by our shops. This applies particularly to steel products of which there has been a great scarcity in many lines.

Unapplied material is money, and the purchase of material represents an investment. If the railroad can use this material as soon as it is delivered, it is a very profitable investment. But if the material lies around unused for months because the railroad has more of this particular kind of material than it needs, or because the mechanical department has changed its plans and has decided to use some other kind of material as frequently happens, then it is a very bad investment and, of course, the Service of Supply is blamed because it must continue to carry this material and absorb the loss due to the interest on the investment and the inevitable depreciation of the material which may be accelerated by obsolescence. But whether the investment be good or bad, it must invariably be proportioned to the financial resources of the railroad. There are many things that you need, both in your business and in your home, things that, if purchased, would save you a great deal of money or increase the enjoyment of your home, but if you do not have the money, you must forgo their purchase. This is frequently the situation in which the railroad finds itself and not unfrequently it is the Service of Supply that is blamed by those who have asked for the material.

One of your correspondents has, if I have not misunderstood him, suggested that the railroad should proceed with the purchase of needed material without regard to its financial resources and depend upon its enhanced earning capacity to create the necessary credit. If matters were as simple as this there would have been no occasion for the railroads to plead poverty before the Interstate Commerce Commission or any real necessity for the recent rate increases to correct a situation that has been fundamentally responsible for the inability of the railroads to properly provide for their needs.

There is, of course, another factor to be reckoned with in any consideration of this subject and that is the efficiency of this much abused Service of Supply. This has an all important bearing on delays to equipment undergoing repairs; which, after all, is what the mechanical department is most concerned about. A simple statement of the facts will serve to illustrate my point and possibly convince some of the mechanical fraternity that what is really needed on every railroad is a strongly organized Service of Supply and that this is the best possible insurance against delays attributable to shortage of material.

"During the period of federal control, the inspectors of the mechanical division were instructed to report to headquarters all shop delays with their cause and duration. All delays attributable to shortage of material were at once reported to the Division of Purchases and were immediately investigated thoroughly on the ground and the conditions remedied. Out of scores of such reports received from all over the country, indiscriminately, only one report referred to conditions on a railroad which has had a properly organized supply department operating for any length of time."

GENERAL STOREKEEPER.

STANDARD METHOD OF PACKING JOURNAL BOXES

TOPEKA, Kan.

TO THE EDITOR:

There were two elements in the discussion of the use of the front plug in the journal box at the A. R. A. Convention that apparently were overlooked. First, the figures quoted on the increased car miles obtained per hot box by leaving out the end plug compared a period when all boxes were repacked with a period when the journal boxes ran until they gave trouble or the car was sent to the shop for repairs. These two periods are not comparable. Second, approximately 40 per cent of all hot boxes have other troubles than poor packing as the cause of their running hot. If the car trucks were given attention many of these defects would be automatically rectified.

The only use of journal box packing is to lubricate the journal. The absorbent power as well as the capillary power of the waste are the only qualities that directly affect the lubricating capacity of the waste. Resilience is an important mechanical characteristics of any good journal box packing. Two journal boxes with equal qualities of waste and packed in the same manner will give equally satisfactory service, other conditions being equal. The condition of the packing under the journal is the essential thing. The use or non-use of a plug in the end of the box does not affect the lubrication of the journal until some other condition obtains. If no end plug is used in the box the packing must be set up each trip or each division. If a plug is used the box will run a much longer time without any attention. It is a question of labor pitted against the plug.

Briefly, the arguments for and against the use of the end plug are as follows:

Arguments Against the Use of the Plug. 1. The box can be better inspected without the plug. 2. The saving of material by leaving the plug out.

Arguments for the Use of the Plug. 1. The plug holds the packing under the journal if properly applied. 2. The plug is an additional oil storage for the lubrication of the journal. 3. The plug will assist in keeping dust from the packing underneath the journal.

If all journal boxes were repacked periodically the packing should always be in good condition and there would not be so much hot box trouble. This repacking must be done in a conscientious and thorough manner to accomplish the desired results.

One of 42 English Tank Locomotives Equipped with Feed Water Heater as Detailed in Fig. 8

LOCOMOTIVE FEED WATER HEATING IN EUROPE

The High Price of Coal Has Stimulated the Use of This Appliance; Over 10,000 Units in Operation

BY ROBERT E. THAYER
European Editor of The Railway Mechanical Engineer

WITH the present cost of coal anywhere from 200 to 1,600 per cent of what it was before the war, the railways of Europe have been forced to consider very carefully means by which locomotives can be operated with a decrease in fuel consumption. Superheating is, of course, quite universally adopted although in England this method of saving fuel has not been developed to the same extent as on the railways in the United States. The use of feedwater

Fig. 1—Arrangement of Weir System of Feedwater Heating

heaters is one means of fuel economy which is now receiving the greatest attention particularly on the Continent. It is estimated that there are over 10,000 feedwater heaters in use on the railways of Europe. These are distributed amongst the Weir system, the Caille-Potonie system and the Knorr system, the latter having by far the greatest distribution. The Weir system is confined almost entirely to Great Britain, the Caille-Potonie to France and the Knorr to Germany, Holland and Switzerland.

The Weir System

The Weir system of feedwater heating consists of a double-acting steam feed pump which takes the water cold from the tender through the pipe *E* forcing it through the heater *A* into the boiler through the discharge pipe *G* as shown in

Fig. 1. The pump is of a vertical type and is of a design largely used in marine service. The heater is shown diagrammatically in Fig. 2. It consists of a bundle of tubes of solid drawn copper expanded into tube plates *E* of rolled brass. These tube plates are fixed to the ends of a mild steel shell by collar bolts which also carry the end covers of the heater. The covers contain dividing ribs which cause the feed water to flow from end to end of the heater, making four passes. The exhaust steam from the cylinders enters the heater at *B* and from the pump at *C*. Thus it will be seen that the exhaust steam surrounds the tubes and with

Fig. 2—Weir Locomotive Feedwater Heater

the feed pump between the heater and the tank the heater is subjected to boiler pressure.

The Caille-Potonie System

The Caille-Potonie system is of the open type, the water flowing from the tank to the feed water heater by gravity, a hot water pump being used to take the heated water from the heater and pump it into the boiler. A diagrammatic out-

line of a recent installation is shown in Fig. 3. The water from the tender passes through the pipe *M* to the "Y" fitting *P* which delivers the water to the top and bottom of the heater. The heated water is taken off at *J* passing through the pipe *Q* to the pump *S*. From there it passes through the pipe *T* to a check valve and into the boiler.

The exhaust steam for heating the feed water is taken from the exhaust nozzle *A* passing through the pipe *C* to the heater. The exhaust from the feed pump also passes to the heater through pipe *X*. The amount of exhaust steam to be taken from the exhaust pipe is regulated by a deflector valve which is set to deflect the proper amount of steam to the heater. The heater itself is kept at atmospheric pressure, a pipe *R* extending up from the top of the heater to above the water line in the tender. This not only provides a means of overflow for the heater but also permits the air and gas formed in heating the water to escape. A spring regulator valve is shown at *D*. This is placed in the pipe *C* between the heater and the exhaust pipes and is so regulated that when the pressure of the exhaust steam in pipe *C* exceeds a predetermined amount the supply of exhaust steam to the heater is reduced. Its purpose is to prevent the feed water in the heater being raised to too great a temperature for the pump to handle. The pump, however, is designed to handle water with a temperature of 209 deg. F. without a loss in its efficiency. As the temperature in the feed water heater increases the pressure of the exhaust steam in pipe

the tubes and the exhaust steam passes through them. Entering at *A*, it makes three passes through the heater, the condensed water passing out through the bottom at *B* and on to the track. The heater is provided with a settling basin which catches the precipitation of any scale forming matter

Fig. 4—Caille-Potonie Locomotive Feedwater Heater

as the water is heated. This basin has a cleaning hole as indicated in the drawing by means of which it can be cleaned every 400 or 500 miles depending upon the character of the water handled. The hot water steam pump in this system

Fig. 3—Arrangement of the Caille-Potonie System of Feedwater Heating

C increases and overcomes the spring of the regulator valve and thus reduce the supply of the exhaust steam to the heater. A pyrometer is placed in the heater discharge pipe, the wires of which pass through the conduit 3 to a gage in the cab. A connection is made in the delivery pipe *T* and piped through *I* back to the cab to a gage which indicates the pressure of the feed water in the delivery pipe. Another connection is made in the delivery pipe for sprinkling the coal in the tender, the water passing up pipe *6* back to a tap in the cab.

The heater itself is shown in Fig. 4. The water surrounds

is located on a level with the feed water heater in order to reduce the lift to a minimum.

The Knorr System

The Knorr system operates with the heater under pressure, the pump being placed between the heater and the tank. Fig. 5 shows the general arrangement of this system. Water from the tender passes to the pump *M* and from there to the boiler *A*, being delivered from there to the boiler through pipe *F*. The exhaust steam is taken from the exhaust passages of the cylinder castings at *G* passing through

the pipe *J* to the heater. Exhaust steam from the air pump passes into the heater through the pipe *L* and the exhaust steam from the feed water pump passes to the heater through the pipe *K*. The condensate from the heater passes to the track through the pipe *R*. An oil pump for lubricating the

Fig. 5—Arrangement of Knorr System of Feedwater Heating

feed water pump is shown at *Q* and *O* is a counter registering the number of the strokes of the feed pump. At *P* is located the steam valve for operating the feed pump. This is controlled, as indicated, from the cab.

This diagram shows a flat feed water heater which is one of the earlier types made but the present standard heater is circular in shape as shown in Fig. 6. Also the condensate

Fig. 6—Knorr Locomotive Feedwater Pump

is shown as being discharged on to the track. More recent installations are arranged for the condensate and steam passing through the heater to discharge into the ashpan. This diagram also shows exhaust steam being taken from the exhaust passages in each cylinder but there are installa-

tions which take the exhaust steam directly from the exhaust pipe.

The heater as shown in Fig 6 consists of a bundle of U-pipes which are held in only one tube plate. The water passes through these tubes making four passes, and the exhaust steam surrounds them. The water enters the heater at *A* and is discharged at *B*. The exhaust steam enters at *CC* and the condensate flows out at *D*. The construction of this heater is such that all of the tubes can be removed intact with tube plate when it is desired. All of the tubes are bent to the same radius and are interchangeable. Any individual tube can be removed and replaced although it will be shortened by the length of its former bearing in the tube plate. With bad water difficulty is experienced in keeping these tubes clean on account of the U-shaped ends.

Development in England

In England but little has been done recently although there is a tendency to seriously consider the application of feed water heaters to locomotives on account of the increase in the cost of fuel. The cost of locomotive coal has increased about 100 and 120 per cent. Almost every road has at some time or other done some experimenting—usually before the war. However at the present time but few locomotives are equipped. Out of twelve railroads, five have none installed, one road has one, two have two, one has five, one has fifty-three and two have some but the number was not stated.

Following are quotations from some of the replies to a letter of inquiry on this subject:

Road A—Our experience with locomotive feed water heaters has been limited to two installations. The results have been satisfactory, there being about 8 per cent saving in coal and 5 per cent in water.

Road B—We equipped five locomotives with feed water heaters in 1912. They are still in service and do not give any particular trouble. However the slight saving obtained

Fig. 7—Knorr Locomotive Feed Water Heater

does not cover interest and depreciation on the first cost, together with repairs.

Road C—We have one locomotive fitted with a feed water heater. In the January, 1914, some tests were made with our dynamometer car while the engine was hauling a passenger train in one direction and a freight train in the opposite direction. There was no appreciable difference between the injectors we are at present using and the feed water heater as fitted.

Road D—Fig. 7 shows a 4-4-2 type side tank passenger engine fitted with a feed water heater. Exhaust steam from the cylinders is admitted to the water tanks through the pipe *A*, the flow of which is controlled by a butterfly valve located at *B* and operated from the footplate. The temperature of the water is thereby rapidly raised, and as the hottest stratum lies at the top it is drawn off through the tubes *C* adjusted to the water level by a copper float, which is hinged at *D* thus allowing water to be taken at all levels by means of the "Weir" feed pump *E* and delivered

to the boiler through an ordinary check valve *F* at an approximate temperature of 180 degs. F. This pump can be set to discharge into the boiler just as much water as is being evaporated and is capable of going very slowly without actually stopping. It is driven by steam and the exhaust is utilized to heat the water in the tanks through pipe *G*. A supplementary heating ejector *H* is also fitted and takes steam from the boiler by means of the steam valve *I*. This is used to heat the water when the engine is being prepared for its day's work, and after it has generated sufficient steam. It is also used in turning the surplus steam into the tanks when the fixed boiler pressure is exceeded, and steam is being blown off at the safety valves. This railroad has 42 engines fitted in this manner.

A similar arrangement of feed water heating is used on ten 4-4-2 tank engines, but in this case the delivery from the feed pump is taken to the check valve *F* fitted on a feed dome on the top of the boiler (Fig. 8). The water at a temperature of approximately 180 degs. *F* enters a closed drum at the center of the feed dome and clear of the delivery pipes *LL*, these being placed at the sides. As the drum fills the water overflows into the delivery pipes *LL* and passes into the boiler. The drum is made deep so that the sediment may be deposited at a sufficient depth from the mouth of the delivery pipes, as it has been found in the shallow domes that, owing to the velocity of delivery, a great bulk of the sediment is carried over into the boiler. A shield plate *M* is fitted over the steam pipe and as the water falls onto it from the pipes *LL* it divides into streams which

Feed Water Heating in France

The principal source of information regarding the development of locomotive feed water heating on French railroads was obtained from the manufacturers of the Caille-Potonie System. There are 146 of this type of heater in use, with

Fig. 9—Feed Dome for Feedwater Delivery

272 on order in France itself. There are 20 in Tunis, 8 in Belgium, 50 in Roumania and 3 in Turkey. Recent tests made by a prominent French road with the apparatus shown in Figs. 3 and 4 have shown a fuel saving of 17.8 per cent in fuel consumption per 100 ton-kilometers over

Fig. 8—Feedwater Heating Apparatus as Applied to English Tank Locomotive

allows it to attain very quickly a temperature equal to that in the boiler. This arrangement has given entire satisfaction.

Road E—We have for many years used the exhaust steam injector, the economy from the use of which we estimate to be between 8 and 10 per cent of coal.

the same locomotive using the injector and there was an increase of 22.3 per cent in evaporation.

The cost of locomotive coal in France has risen over 700 per cent and there has been a manifest interest in feed water heating as shown by the large number of feed water heaters on order.

Feed Water Heating in Belgium

The following abstract of a letter from Belgium indicates clearly the situation there.

Before the war we had decided to experiment with various systems of feed water heaters. Our object was not so much to find out what economy could be effected by the use of pre-heaters to a locomotive—the importance of which economy is incontestable—as to compare the systems in question from the point of view of efficacy, smooth working and upkeep. The war prevented us going on with the matter.

Among the locomotives supplied to us by the Germans in virtue of the terms of the armistice, a fairly large number are fitted up with the Knorr heaters. The present condition of the service has not permitted us to try experiments with a view to determining the economies resulting from its use. The Knorr apparatus has caused a certain number of mishaps specially affecting the heater tubes. At the beginning some difficulties were met with on account of the inexperience of the staff, but these have now disappeared.

With the view to making comparisons we have also decided to fit feed water heaters to some of the locomotives which are at present in the course of construction. Ten of the Consolidation locomotives which are ordered from England will be fitted with the "Weir" heater and five of the Consolidated locomotives ordered from America will be fitted with the "Worthington" heater.

Feed Water Heaters in Holland

The railways of Holland have also a "coal problem." The price of locomotive coal has increased about 1,200 per cent from since before the war, and locomotive feed water heating has become very popular. This country uses the Knorr system entirely. There are about 300 locomotives out of a total of about 1,000, that are equipped and the present program calls for the application of heaters to all of the principal locomotives. This includes locomotives weighing from below 50 tons to the heaviest locomotive of 102 tons. The railways in Holland have made no conclusive tests with the feed water heater but it is claimed that a feed temperature of from 190 to 210 degs. F. is obtained.

Feed Water Heating in Switzerland

The situation in Switzerland is well outlined in the following abstract of a letter from the chief mechanical engineer of the Swiss Federal railways:

The first experiment with locomotive feed water heaters on the Swiss Federal railways was undertaken on a new 4-cylinder simple, superheated locomotive, which was put into service at the end of 1913. The locomotive was fitted with an exhaust steam and smoke box heater in conjunction with a Westinghouse feed pump. This experiment was not satisfactory; the exhaust heater was much too small, it required much repairing on account of faulty construction, the smoke box heater hindered the passage of gases so much that to obtain a sufficient head of steam about half the tubes of this heater had to be removed, so that the heating surface was reduced from the original 253 sq. ft. to 134 sq. ft. This feed heater also required much repairing, as the thin tubes became bent and cracks appeared in them. In 1915, therefore, both feed-heaters were removed, the exhaust heater with the feed pump being applied to a smaller superheated compound locomotive for which it is suitable.

At the beginning of 1915 two new superheated compound locomotives were put into service with exhaust feed heaters; one locomotive was fitted with a Westinghouse feed pump and a feed heater from the Winterthur Locomotive Works, the other with a Knorr feed pump and Knorr feed heater. Both arrangements have proved successful.

On the trial runs, which were carried out on the section Erstfeld-Göschenen (Gotthard railway), with a continuous

ascent of 2.5 and 2.6 per cent, a saving in coal of about 10 per cent per 100 ton-kilometer was established for engines with feed heater in comparison with engines of similar construction without feed heater. The performance of the engines have been improved quite considerably in consequence of the installment of feed heaters. Therefore the 15 superheated compound locomotives delivered in 1916 and 1917 have all been fitted with exhaust feed heaters, and feed pumps. Old Westinghouse air pumps have been used, with their air-cylinders replaced by water cylinders in conjunction with a suction chamber. In the meantime, for the remaining 11 superheated compound locomotives feed heaters of the Knorr pattern have been ordered.

It has been found that the saving from feed heating on locomotives traveling chiefly on lines with alternately rising and falling gradients is small. The feed heaters are only suited for long sections which are run under steam.

There are in all up to the present 21 locomotives already provided with feed heaters and 11 others are shortly to be fitted with them.

Development in Germany

Locomotive feed water heating in Germany is now as common as superheating in the United States. It is estimated that there are over 10,000 locomotives so equipped. It is not an after-the-war development there, for as early as 1909 the German railways began investigations and installations on a large scale were made soon after that. The Knorr system was adopted as standard and by the end of 1912 about 3,000 heaters were installed. At the present time there are well over 10,000 in operation and they are being applied at the rate of 2,000 a year. All new locomotives are equipped with this device and many old locomotives. With coal costing 200 marks now, as against a price of 12.5 marks before the war, it is estimated that the feed water heaters pay for themselves through the economies effected in less than one year.

The only test data available in regard to this system of feed water heating are the results of tests made in 1913 on a passenger locomotive (Type 2-B) over a distance of 91 miles between Grunewald, just outside of Berlin, and Gusten. Three tests were made, one without the heater—Test A—one with the heater—Test B—under the same conditions as test A, and the third—Test C—with the heater and a heavier train. During test C two more stops were made than in test A and B, but notwithstanding this fact the running time of test C was less than either tests A or B. The following table gives a summary of the results of these tests:

	Test A	Test B	Test C	Percentage Difference B over A	Percentage Difference C over A
Feed water heater.....	No	Yes	Yes		
Running time (min.).....	129	131	125	1.5	-3.1
Train load (tons).....	348	348	353	...	1.4
Coal consumption (lb.)....	5,672	4,300	5,400	-24.3	-4.8
Ton-miles per lb of coal...	5.59	7.37	5.95	31.8	6.4
Water consumption (lb.)...	31,000	31,900	36,100	9.2	16.4
Evaporation.....	5.45	7.42	6.68	36.1	22.6
Coal per sq. ft. of grate area per hr. (lb.).....	108.5	80.9	106.5	-25.4	-1.8

It will be observed that there is a decided increase in the efficiency of the locomotive in Test B over that in Test A, although the same load was hauled. Test C indicates that even a heavier load can be hauled when the feed water heater is used, with a decrease in fuel consumption and an increase in evaporative efficiency, than when the heater is not used.

The service rendered by the heaters has done much to relieve the severe locomotive shortage the German railways experienced after the war. In a paper before the Verein Deutscher Maschinen-Ingenieure in December, 1912, Gustav Hammer, who is now the chief locomotive engineer of the Prussian-Hessian System, said that the principal reasons for the rapid introduction of feed water heating by exhaust steam are the greater economy obtained by the saving of coal and the increase of efficiency without the weight of the en-

gines being increased much. The greatest economy in coal is naturally obtained with engines having the highest steam consumption and such engines cause a heavy strain on the boiler. The economical results obtained are not only due to the fact that a large amount of the heat from the exhaust steam is reclaimed, but also because it reduces the rate at which the fuel is burned on the grate. Both of these factors increase the efficiency of the boiler. *According to the conditions of the traffic the saving of coal varies, but, on an average, it may at least be 10 per cent.*

More important still is the increase of the efficiency of the engine as a whole. If the friction weight and the efficiency of the machine are sufficient and only that of the boiler fails this can be quite considerably increased by feed water heating. This is especially important for lines the permanent way and bridges of which do not allow a special increase of wheel loads. The tests of the Royal Railway Central Office, which were very thorough, have shown increases of the efficiency of the boilers of 20 per cent and more, in a way that cannot be disproved. In particular, these tests have shown that, with superheated steam engines, under otherwise identical circumstances, the production of steam can be increased from 12.5 lb. to 15.4 lb. per sq. ft. per hour by exhaust steam heating.

The preservation of the boiler is to be considered as a further very great advantage of the feed water heating. This preservation is, first of all, brought about by the smaller heating surface required with the same efficiency in comparison with the ordinary engine as about 1/6 of the heat contained in the exhaust steam is regained. It further results from the difference in the feeding of the boiler as well. When using the heater, the supply of feed water must be adapted to the consumption as exactly as possible. It is not an intermittent feeding, but a continuous one by the steam feed water pump, which can be adjusted very easily, and within any limits. It is not the same with the injector. Furthermore, the boiler is supplied with water at a lower temperature with the injector than with the heater. The boilers properly fed with heated water must be considerably better and have a greater life than those fed with injectors only.

MOUNTAIN TYPE FREIGHT LOCOMOTIVES FOR THE SOUTH AFRICAN RAILWAYS

While it is true that locomotives built in accordance with American practice have demonstrated their fitness for service in all parts of the world, there are many railways which, for good and sufficient reasons, when purchasing locomotives from builders in the United States, specify that European designs be followed. American builders have had considerable experience in work of this kind, even to the extent of building locomotives throughout to the metric system of measurement.

The Baldwin Locomotive works have recently constructed thirty locomotives for the South African Railways, built throughout in accordance with the railways' designs and specifications. The South African lines are built to a gage of 3 ft. 6 in., and in view of the narrow gage and clearance limits, the motive power is conspicuous because of its exceptional weight and capacity. The new locomotives are of the 4-8-2 type, and the average weight carried per pair of coupled wheels is very nearly 38,000 lb. The tractive effort is 41,700 lb., which compares favorably with the motive power used on standard gage lines in the United States.

Locomotives of this general design have been in service on the South African Railways for some time, working between the Witbank coal fields and Johannesburg, hauling trains of 1,400 tons over this 80-mile stretch of track, the maximum grades being 1 per cent. The locomotives are designed to traverse curves of 300 ft. radius.

The new Baldwin engines have straight top boilers, with wide fireboxes of the Belpaire type. The inside fire-box plates are of copper, a material which has given excellent service results in this district, where the water used is of exceptionally poor quality. A fire-tube superheater is installed, and the steam temperatures are indicated by the permanent installation of an electric pyrometer.

The frames are of the plate type, which were shipped completely assembled with cross-ties, cylinder saddle, cylinders, guides and guide yoke. The pistons were in the cylinders, and the cross-heads in the guides. This type of sub-assembly makes for considerable convenience in the final erection.

The equipment of these locomotives includes American steam brakes on the coupled wheels, and automatic vacuum brakes on the tender, with train connections. The special equipment includes Hasler speed recorders and a power operated grate shaker. On the right hand side of this locomotive is located a combination steam and hydraulic reverse mechanism, connected directly to the reversing shaft of the locomotive. This mechanism consists of one steam cylinder and one water cylinder. The two cylinder pistons are connected to a common piston rod, which in turn is fastened to the reverse shaft arm. The water cylinder is simply a cylinder with passages from one end to the other, and is entirely filled with water. This cylinder acts as a locking device for the holding of the reverse shaft in a desired position. The steam cylinder is used for moving the reverse shaft and at the same time causing the water piston to move it. When the steam valve in the cab is closed, the steam ceases to function and the water cylinder, by having equal pressure on both sides of the piston holds the gear in the proper position.

General Data

Gage	3 ft. 6 in.
Service	Freight
Fuel	Coal
Tractive effort	41,700 lb.
Weight in working order	205,100 lb.
Weight on drivers	151,900 lb.

GOVERNMENT TESTS OF WATER-INDICATING DEVICES

Tests Demonstrate Unreliability of Many Water Indicating Appliances on Modern Locomotives *

THE development of the locomotive has created new difficulties in design, construction, maintenance and operation. One of the perplexing problems which has presented itself is that of securing a correct indication of the height of water over the crown sheet under all conditions of service.

The grave importance of this matter is evidenced by the number of crown sheets damaged, due to low water, where careful investigation fails to disclose any contributory cause.

In the locomotive boiler, which usually has a sloping back head and is generally equipped with arch tubes and brick arch, the heat is severely impinged on the door sheet and back end of crown sheet, creating severe agitation and rapid circulation up the back head and through the arch tubes. The water glasses and gage cocks, as generally applied, only indicate a corresponding level of water while the locomotive is at rest and with no steam escaping. When the safety valves lift or with the throttle valve open and the locomotive in operation, the gage cocks, when applied directly in the boiler, indicate a higher level of water than do the water glasses when they are properly applied and maintained. This discrepancy between the registrations of these devices has heretofore, been taken as a matter of natural consequence, and little consideration given to the cause or the result of the conflicting registrations.

Practically all enginemen and others having to do with the operation of the locomotive, true to a common understanding, believe that the correct height of water over the crown sheet is always indicated by the gage cocks, and that the level indicated by the water glass is unreliable and not to be depended upon; therefore it is reasonable to believe that enginemen have frequently depended upon a level of water indicated by the gage cocks as being correct, when in fact the true level was much lower, and, as a consequence, damaged crown sheets have resulted.

Realizing that this variation creates an unsafe condition and that its cause should be determined and a remedy applied, experiments have been made with different devices, on a number of locomotives of different classes, on fourteen railroads in various sections of the country, for the purpose of determining the action of the water in the boiler and its effect upon the gage cocks and water glasses.

Excerpts from tests made on five railroads on which the most extensive tests were conducted will serve to briefly describe the surprising conditions disclosed. During all of these tests and observations, representatives of the Bureau of Locomotive Inspection were accompanied and ably assisted by representatives from the mechanical department of the various railroads.

Summary of Tests

The locomotives on which the first series of tests was made were of the 2-8-8-2 mallet compound type, used in bad-water districts, equipped with boilers of the crown bar type, with wide fireboxes and Schmidt superheaters, and used oil for fuel. The devices for indicating the water level consisted of three gage cocks spaced 3 inches apart and applied directly in the back head near the knuckle, at right angles to the sloping sheet, and one water glass with bottom connection entering the back head approximately 3 inches below the back end of the crown sheet, and the top

connection entering the back head 2 inches below the knuckle. The lowest reading of the water glass and gage cocks was $3\frac{5}{8}$ in. above the highest part of the crown sheet.

The back heads of these boilers were braced by a "T" iron, extending crosswise, at approximately the same level as the back end of the crown sheet.

In order to determine the action of the water as indicated by these appliances, observations were made during five trips in freight service, covering a distance of 680 miles, under varying operating conditions and on varying gradients.

With the locomotive on straight track and no indication of foaming, water would issue from the top gage cock when it was opened, both while standing and in operation, while the safety valves were open or the throttle valve open, regardless of the water level in the boiler as registered by the water glass.

At the completion of the fifth trip, three additional gage cocks were applied in the back head, parallel with the horizontal center line of the boiler, the top one entering the back head $10\frac{1}{2}$ in. below the top knuckle and $10\frac{1}{2}$ in. to the right of the vertical center line, with the same vertical reading as the standard application, and will hereafter be known as "experimental gage cocks." These were applied for the purpose of determining the effect of changing their location toward the vertical center line of the back head and away from the knuckle, where the upward circulation of the water was believed to be greater than near the center.

An experimental water glass was also applied on the left side of the boiler, opposite the back flue sheet, the top connection of which entered the wrapper sheet on the top center line, 15 in. back from the throttle dome, while the bottom connection entered the wrapper sheet on the side. The lowest reading of this glass was 1 inch above the highest part of the crown sheet. This glass will hereafter be known as the "experimental water glass."

With this arrangement, observations were made during five additional trips, when the same conditions were found to exist that had been noted in the previous tests, with respect to the original gage cocks, namely, full water showed at the top gage cock, regardless of the level indicated by the water glasses, while the experimental gage cocks indicated a level approaching that indicated by the water glasses while operating with open throttle or safety valves blowing.

While operating with throttle wide open and water glass three-fourths full, the bottom connections to both water glasses were frequently closed and drain valves opened, when dry steam would steadily flow through the experimental water glass and solid water would flow through the original water glass, which glass also showed the water in severe agitation while the locomotive was in operation. These experiments demonstrated that the level of water indicated by the gage cocks and water glasses varied with their point of connection with the boiler, and indicated that a higher level of water prevailed at the back head than existed further ahead.

It is believed that the transverse "T" iron, which was applied to the back heads of these boilers, hindered the movement of water up the back head near the center, and consequently decreased the variation between the level of water indicated by the experimental gage cocks and that registered by the water glass.

As a result of these experiments, which were brought about

*This account tests recently conducted by the Bureau of Locomotive Inspection was prepared by A. G. Pack, chief inspector, through whose courtesy the article is published.

by the large number of crown sheets being damaged and fusible plugs being melted, the gage cocks and water glasses were moved toward the vertical center line of the boiler, which seems to have relieved the situation to a considerable extent.

Second Series of Tests

It having been concluded that the false registration of the gage cocks, when screwed directly in the boiler back head, and the agitation of the water in the water glass when top connection is made near the knuckle, were due to the rapid circulation of the water upward, carrying it a considerable distance above the level further ahead, a number of locomotives of the following description were equipped with water columns, as shown by Fig. 1:

These locomotives were of the Santa Fe or 2-10-2 type, equipped with Schmidt superheaters, Street stokers, used bituminous coal for fuel, carried 180 pounds steam pressure, with firebox 132 inches long and 96 inches wide, with brick

Fig. 1—Water Indicating Devices Used In Preliminary Tests

arch supported by four arch tubes and back head sloping 15° from vertical.

The water column applied on these boilers, as illustrated by Fig. 1, was $1\frac{3}{4}$ in. inside diameter and 16 in. long, applied in a vertical position on the back head, 18 in. to the right of the vertical center line. The top connection was made by means of an angle valve with extension handle, extending through the top of cab, and copper pipe $1\frac{1}{16}$ in. inside diameter, entering the wrapper sheet $12\frac{1}{2}$ in. in front of the back head knuckle and $14\frac{1}{2}$ in. to the right of the top center line. The bottom connection was made of copper pipe $1\frac{1}{16}$ in. inside diameter, and entered the back head, through a three-way cock, 16 in. to the right of the vertical center line and 28 in. below the back end of the crown sheet. Three standard gage cocks with $\frac{3}{8}$ inch openings were attached to the right side of this column, three inches apart. One water glass was also attached, with standard fittings, having $\frac{1}{4}$ inch opening. The lowest reading of both water glass and gage cocks was $4\frac{1}{2}$ in. above the highest part of the crown sheet.

By this arrangement, it was believed that when entering the boiler far enough ahead of the back knuckle to obtain dry steam at all times through the top connection to the column, and by taking water from well below the crown sheet and below the agitated portion of water, a more correct

reading could be obtained than when the gage cocks were screwed directly to the boiler head. During the approximate six-month period that these locomotives were operated with this arrangement, however, very considerable trouble was encountered, due to the extremely erratic and unreliable water indications.

When the matter was brought to the attention of the Bureau of Locomotive Inspection it was determined that something should be done to learn just what caused the trouble. Therefore, one round trip was made, covering 240 miles, where observations were taken under actual operating conditions, with the following general conditions noted:

At first start there was $3\frac{1}{2}$ inches of water in the glass, reverse lever in full forward motion, with engine working up to the slipping point and working considerable water through the cylinders for about two miles. When locomotive was started the water in the glass receded very rapidly until it disappeared. The left injector was started and by opening any of the gage cocks, which had openings $\frac{3}{8}$ inch

in diameter, after the water had disappeared, dry steam was emitted for a few seconds, when the water in glass and column would rise to the cock that was opened and would be maintained unsteadily at the same level until the gage cock was closed, when the water in the glass would instantly recede slightly below this cock, which would be two to five inches higher than the level indicated before the gage cock was opened. From this point the water would gradually recede, taking four or five minutes to drop to the low point, and, when reached, the water would work normally in the glass, but would gradually recede to different levels and sometimes out of sight, depending upon the temperature of the water in the lower connection to the column.

This test was made many times during the trip and in all cases practically the same results were obtained. When the drain cock to the water glass was opened, the water in the glass and column would be raised as a result, and, when closed, the same receding conditions prevailed as when the experiments were made with the gage cocks, but would again settle upon an indefinite point, sometimes out of sight, depending upon the temperature of the lower column connection. The gage cock was frequently opened slightly, so as to create a slight circulation through the column, which kept the temperature in the column and connection approximately that in the boiler, during which time the column glass and gage cocks appeared to register correctly.

Numerous other observations were made, which gave results similar to those outlined above. During these tests the temperature of the atmosphere was below zero, which caused the water in the column and in the long pipe by which the bottom connection was made to cool rapidly, which in turn caused the level of water in the column to lower. In order to demonstrate that this reduction in temperature was the cause of the receding action in the column, ice water was poured on the bottom of the column. This caused the water in the column to lower very quickly while being cooled, and it would rise as soon as circulation was again established in the column.

It was demonstrated by experiments that this lowering of water in the column was due to the volume of dead water contained in the long pipe through which the bottom connection to the column was made. This was evidently due to the density and weight of the water at different temperatures, the temperature being much lower than that of the water in the boiler, due to the pipe and column being exposed to the cold atmosphere without circulation.

After noting these results and for the purpose of comparison, another water glass and set of three gage cocks were applied in the usual manner, as illustrated by Fig. 1, the water glass connections entered the back head at the left of column and the gage cocks entered near the knuckle. The comparative readings of all gage cocks and water glasses corresponded. For reference purposes the gage cocks and water glass applied to the column will be referred to as No. 1, while those applied in the usual way will be referred to as No. 2.

With the indicating devices arranged as outlined, observations were made during three successive trips, or 720 miles, when the following general results were noted:

Previous to starting, all devices indicated a corresponding level, but, when the throttle was opened or safety valves lifted, the water in No. 1 glass would recede approximately 2 in., while that in No. 2 glass would rise. No. 2 glass indicated a level of water from 1 in. to 3 in. higher than that indicated by No. 1 glass. In some cases, however, the water was out of sight at the bottom of No. 1 glass, while No. 2 glass indicated a level of from 3 in. to 5 in.

After noting these results, the following change was made: The bottom connection to the water column was raised 28 in. and moved to the right 2½ in. The new connection was made *midway between the two right arch tubes* and approximately 10 inches above them, about in line with the back end of the crown sheet. The object of this change was to move the bottom connection up as close to the lower end of the column as possible, and to reduce the volume of dead water in this connection in order to eliminate the lowering effect referred to. After this change had been made, the following general results were obtained: When starting, the level in both water glasses rose slightly and both glasses worked normally; and when the throttle was closed the level would recede slightly, the readings of both glasses corresponding under all conditions of service.

A comparison of the No. 1 gage cocks with the No. 2 water glass showed that they registered the same level when the gage cocks were opened moderately, or a sufficient amount to obtain a correct reading, but by opening the No. 1 gage cocks an excessive amount, or wide open, the water in the column and attached glass would rise from the bottom to the level of the cock opened. When the gage cock was closed, the water would instantly recede to its original working level and correspond with that shown in No. 2 glass. The receding action, as noted in the previous tests and before the bottom connection was raised, was entirely absent and the water registered a corresponding level in both No. 1 and No. 2 glasses under all conditions of service.

Tests of the No. 2 gage cocks, located as they were near the knuckle of the back head, proved that they were wholly

unreliable for the purpose of registering the correct level of the water in the boiler while the locomotive was working, as they showed full water at all times, throughout the entire test, regardless of the level indicated by the water glasses and No. 1 gage cocks while steam was being rapidly discharged from the boiler, due, without question, to the rise of water up the back head. While standing, and with no steam escaping, the readings of both water glasses and all gage cocks registered alike.

Further observations and tests were made while on heavy grades, but no unusual or improper conditions could be noted except that No. 2 gage cocks registered full at all times, as previously stated, and the water in the column glass could be raised to the height of the gage cock opened, when opened excessively.

The opening in the bottom connection to the water column was then reduced to ¾-in. and observations continued. It was thought that by restricting the inlet at the bottom of the column it would prevent the water from rising in the column and attached glass when the gage cocks were opened excessively. The opening in the gage cocks was also reduced from ⅝ in. to ¼ in. inside diameter, so as to disturb the equilibrium of the water in the column as little as possible.

On this trip particular attention was given to the action of the water, as registered by the water glasses and No. 1 gage cocks by comparison, and it was particularly noted that the level of the water corresponded at all times under the varying conditions of service, while the standard gage cocks registered full water at all times with a high evaporation taking place.

As previously stated, in the original arrangement the top connection to the column was fitted with an inaccessible valve, the handle of which extended through the roof of the cab, thus making it difficult to tell whether or not the valve was open and the column in communication with the boiler at the top. In order to eliminate the possibility of these valves being left closed through carelessness, as is often done with water glass cocks, they were removed. The necessity for removing these valves was demonstrated by the serious damage to a crown sheet, by overheating, while the water showed in the water glass and the column gage cocks, due to one of these valves having been left closed on one occasion, while the locomotive was being prepared for service.

Third Series of Tests

The locomotives on which these tests were made were U. S. Railroad Administration standardized heavily Mallet 2-8-8-2 B type, with boiler and firebox of the following dimensions:

Boiler, type	Straight top
Boiler, pressure	240 lb.
Firebox, length	170 ¼ in.
Firebox, length of grate	143 ¾ in.
Firebox width	96 ¼ in.
Combustion chamber, length	37 in.
Heating surface, tubes and flues	5,685 sq. ft.
Heating surface, firebox	386 sq. ft.
Heating surface, arch tubes	49 sq. ft.
Heating surface (total)	6,120 sq. ft.
Grate area	96 sq. ft.

The crown sheet was 15 ft. 7 in. in length, with firebox equipped with Gaines furnace, and brick arch extending to within 68 in. of the door sheet and within 22½ in. of the crown sheet, supported by five 3½-in. arch tubes, using bituminous coal for fuel and fired with Duplex stoker. The boiler was equipped with one water column to which three gage cocks and one water glass were attached. Two gage cocks were applied directly in the back head and two water glasses applied in the usual manner, one on each side of the vertical center line of the back head as illustrated by Fig. 2.

The lowest reading of the gage cocks attached to the water column, and all water glasses, was 8 in. above

the highest point of the crown sheet and $1\frac{3}{8}$ in. below the top of boiler back head. The limited dry steam space at the back end of this boiler had a marked effect on the readings of these devices when connected in the back boiler head.

Numerous observations were made on a number of locomotives of the same type, for the purpose of comparing the action of the water in the gage cocks and water glasses as originally applied and after certain changes were made. For the sake of brevity, however, the tests made on only one of these locomotives will be described, inasmuch as the results obtained were the same in all cases.

For the purpose of comparison, each of the connections was fitted with a valve, and extension handle, so they could be easily opened and closed, allowing changes from one to the other at will. The top connection to the right water glass was changed from its original location, which corresponded to that shown for the left one, to the location shown at B1 on the highest part of back head knuckle.

It will be readily understood that when water, from any cause, reaches the top connection, it destroys the proper registrations of these devices, and the idea in mind, when arranging the top connections in the manner illustrated, was to determine whether or not the reading of the water glasses and water column would be altered when changing from one connection to the other, which were in line with the upward flow of water between the door sheet and the back head, the object being to obtain dry steam to balance the volume of water in the water glasses and water column. The result of changing from one connection to the other was indeed surprising.

Fig. 2—Water Indicating Devices Used in Third Series of Tests

With the locomotive equipped with water glasses and gage cocks, as shown by Fig. 2, it was used in pusher service, on an ascending grade of 61 feet per mile, during five successive trips, occupying a period of time aggregating four hours and twenty-five minutes.

While the locomotive was standing, with no steam escaping, the registration of all devices showed a corresponding level of water. A total of 121 readings were taken and recorded while on straight track and while the locomotive was working with heavy throttle with about the same firebox temperature and steam pressure.

For reference purposes, the water glasses and water column, with their connections, are referred to by letters and figures as follows:

A.—Water column to which three standard gage cocks were applied.

Ax.—Water glass applied to water column.

A1.—Water column connection where it entered boiler on back head knuckle $\frac{1}{2}$ in. higher than top gage cock and $6\frac{5}{8}$ in. below highest part of back head as originally applied.

A2.—Water column connection where it entered boiler at highest point of back head knuckle.

A3.—Water column connection where it entered boiler on top center line in front of back head.

B.—Right water glass.

B1.—Right water glass connection where it entered boiler in back head knuckle.

B2.—Right water glass connection where it entered boiler in front of back head.

C.—Left water glass.

C1.—Left water glass connection where it entered back head knuckle $4\frac{1}{2}$ in. below highest point of back head, measured vertically and $2\frac{1}{8}$ in. above top water glass reading, as originally applied.

C2.—Left water glass connection where it entered boiler in front of back head.

With the locomotive working heavy throttle, column A and glass Ax, connected at A1, the original connection, would be completely filled, while glass B, connected at B1, indicated 1 inch of water. By changing the connection A1 to A2, the water would instantly recede to a level in A and Ax corresponding with that indicated by glass B, or 1 inch, when A, Ax and B would continue to correspond while connected at A2 and B1, until the reading approached $4\frac{1}{2}$ to 5 in., at which point the water would become erratic and soon fill column A and glasses Ax and B if the injector was slightly over-supplying the boiler, or would recede and correspond if the water was slightly lowering in the

boiler. This indicated that the water was moving up the back head, with fountain effect, to a point reaching the connections A2 and B1 where they entered the top knuckle of the back head, $8\frac{1}{8}$ in. higher than they registered when connected at A3 and B2 on the wrapper sheet, and was illustrated by changing the connection to column A and glass B from A2 to A3, B1 to B2, when the water would instantly recede to its former reading, and the readings would then continue to correspond as long as the connections remained at A3 and B2, without regard to condition of service or height of water indicated.

These readings could be varied as often as desired, by shifting connections to the boiler by use of the valves; that is, when the column connection was changed from A3 to A2, the water would immediately go from 5 in. to out of sight in glass Ax, and top gage cock would show full water; or, when changed from A2 to A3 the water would

recede from out of sight to a level of 5 in. and correspond to the reading shown by glass B connected at B2. With glass B connected at B1, the reading would correspond with column A and glass Ax when connected at A3, until the level approached 5 in., when the water in glass B would become erratic and soon fill the glass, while column A and glass Ax, connected at A3, retained their level of 5 in.

These experiments illustrated that column A and glass Ax were incorrect when connected at A1, the original connection, with 1 inch or more of water; and, when connected at A2, were incorrect when the level indicated exceeded 4½ in. to 5 in.; and correct at all times when connected at A3; and that glass B was correct when connected at B1, until the reading indicated 4½ in. to 5 in., and incorrect when more water was shown, until connection was changed to B2.

With glass B registering 5 in. of water, the connection was changed from B2 to B1, when the glass would immediately fill; and with the bottom water glass cock closed and drain valve open, solid water flowed steadily through the drain pipe, which showed conclusively that the flow of water up the back head, with fountain effect, reached the connection B1 where it entered the back head knuckle 8½ in. higher than the correct level of water in the boiler or that registered by glass B when connected at B2, and by A and Ax when connected at A3.

With glass C in communication with the boiler at C1, its original connection, it registered a level corresponding to that indicated by column A, glass Ax when connected at A3, and with glass B when connected at B2, until the water registered 2½ in. to 3 in., at which time the water in glass C would become erratic, rising and lowering and rapidly filling, providing the injector was more than supplying the boiler, notwithstanding column A and glasses Ax and B, connected at A3 and B2, worked normally and indicated 2½ in. to 3 in. of water.

When glass C communication was changed from C1 to C2, the water would instantly recede from out of sight at top to a level of 2½ in. to 3 in. and give a corresponding reading with column A and glasses Ax and B, which was true at all times when all connections were made ahead of back knuckle, regardless of the condition of service or the level of water in the boiler.

The reading of glass C, when it indicated in. or more of water, could be changed as frequently as it was desired, by changing the communications from C1 to C2 or vice versa.

It was noted on one occasion, with column A connected at A1, glass B connected at B2 and glass C connected at C1, the locomotive moved to a left-hand curve, at which time water glass B registered 2 in. of water while column A and glasses Ax and C were completely filled.

Sixteen readings were taken on the fourth trip, with column A connected at A1, the original connection, glass B at B2 and glass C at C1, original connection, during which time glass B indicated a level of from 1¼ in. to 4¾ in., while glasses Ax and C and all gage cocks in both column and back head showed full of water. In fact the gage cocks applied directly in the back head showed full of water at all times during these tests, while the locomotive was being operated or when the safety valves were open.

By referring to Fig. 2, it will be noted that connections to water glasses are made to the boiler through ell connections. In changing the street ells from their original location on the back head to the location shown at B2 and C2, the C2 connection was tapped so as to drain thoroughly, while B2 was leaned sufficiently to cause a trap to be formed. This trap caused the water in B glass to rise 2 in. to 3 in. higher than that registered by the left glass; and when this trap was removed, the water indication in all

three glasses corresponded. This condition has been found in a number of the locomotives under investigation, when, as soon as the traps were removed, the discrepancies were obviated.

(To be continued)

FUEL STATIONS

At the 1915 convention several devices were reported for measuring the coal as delivered to locomotives, but at that time none of the suggested equipments had been extensively used. Since that date, however, there has been a considerable number of at least two of the suggested types of equipments installed and maintained regularly in service.

One of the earliest installations is that of the Nashville, Chattanooga & St. Louis at Cowan, Tennessee. These machines have been operating since 1916 with an average issue of 200 tons of coal per day and have handled up to a recent date approximately 192,000 tons. This railroad also has six additional equipments of the same type at three other points. At one of these stations the record for the past twenty months,

Fig. 1—Coal Measuring Device, N. C. & St. L.

with no break-down, indicates 150,000 tons of coal issued, one device recording 88,234 tons.

Fig. 1 outlines the general arrangement of this type of measuring device and illustrates its application to an existing chute. This machine is operated with a two-horsepower electric motor in one continuous rotary movement in one direction. It is so designed that as the delivery gate is opened, the undercut gate arm rolls on the surface of the large cam, in that way locking it. When the undercut gate is down, ready to receive the issue of coal from the bin, the delivery gate is also locked, and these movements alternate so that it is impossible to have both gates open at the same time and thus release a bin full of coal. The ordinary operation is five cycles per minute. As first constructed, the cut gears used

*From a report presented at the 1920 convention of the International Railway Fuel Association.

were made of cast iron. These broke in several instances, so that all steel gears are now used with the equipment.

There is one feature in connection with the use of such power driven machinery as this which should be mentioned, and that is, that it is a practical necessity to have the coal issued by the assigned operator at the coaling station. Such a mechanism should not be handled promiscuously by many different men, most of whom would know nothing beforehand of its construction or method of operation. This equipment, the same as other parts of mechanically operated coal chutes, requires regular and systematic attention and maintenance.

As illustrating the second type of measuring device, the Chicago, Milwaukee & St. Paul in 1918 installed the equipment shown in Fig. 2 on a 75-ton coal chute at Jackson, Minn. With this equipment the operator, after lowering the chute into position, discharges the coal from the measure by pulling on the operating rope. The locked-in position of the unbalanced measure is thus released and the entrained coal is discharged, the inlet gate being automatically closed. When the measured coal is all discharged, a second pull on the operating rope tilts the measure back

Fig. 2—Coal Measuring Device, Jackson, Minn., C. M. & St. P.

again to the filling position, closes the outlet gate and opens the inlet gate. As the measure is again filled the operations are repeated. The reported time for taking five measures or five tons of coal is three minutes, that is, from the instant that the engine stopped in front of the chute until it started away. There are 14 engines taking coal at this point, averaging 5.8 tons per engine. A recent report on this particular installation advises that, "There is no question in our minds, however, but that this device gives much closer approximation to correct weights than the old method of estimating weights. The device appears to be satisfactory to all concerned and it costs much less to install than scales."

Discussions and reports presented at the convention from year to year have called attention to the necessity of delivering the coal into the storage bin in such a manner that the

fine and coarse coal will not segregate, with the resulting effect that one locomotive tender will receive all coarse lump coal and the next one get only the fine and in some cases almost powdered coal. The coal should fall on the pile in the bin at a point directly over the discharge opening. The natural separation of the coarse coal toward the lower edge of the pile will not then materially affect a fairly uniform mixture of the coarse and fine coal at the point of discharge. Fig. 3 illustrates the arrangement which caused the trouble. The bucket conveyor delivered the coal over the idler at the

Fig. 3—Improper Discharge of Coal to Storage Bins

center of the bin. The coal then dropped to the upper ends of the two inclines shown, but in passing over the edge of the conveyor, practically all the lumps threw over onto the long incline and only fine coal dropped onto the short incline. Further, the momentum of the coal on the long incline was such that the coarse coal was all delivered on the pile against the left hand wall of the bin and as the bin was filled full only fine coal worked over the center ridge to the right hand discharge opening. By eliminating the inclines and providing a discharge opening in the conveyor directly over the center of the right half of the bin, coal is being delivered to each of the two tracks well and uniformly mixed.

Another railway reports satisfactory improvement in the mixing of the coarse and fine coal by the use of a baffle at the lower end of the distributing chutes. The purpose is to deflect the lumps downward so that they will fall vertically with the slack instead of falling over to one side of the pocket and there forming a mass of lump coal. However, this does not, as arranged, apparently entirely eliminate the separation trouble.

[The report included a number of illustrations of typical fuel oil stations, which were presented without critical comment.—EDITOR.]

The report was signed by W. E. Dunham (Chairman), C. & N. W.; E. E. Barrett, J. C. Flanagan, J. W. Hardy, W. T. Krausch, R. A. Ogle, J. L. Ripley, C. F. Luddington, C. M. & St. P., and J. E. Nellegar.

OIL BURNING ENGINE EXPLODES.—A yard engine used for shifting cars in the Mt. Clare yards of the Baltimore & Ohio recently exploded, injuring seven men. While the cause of the accident has not been determined, it is believed that one of the feeds became clogged, allowing the oil to back up and generating considerable gas.

Italian Locomotive Equipped for Burning Pulverized Coal

PULVERIZED COAL BURNING EQUIPMENT FOR EUROPE

Description of Locomotives Recently Designed to Utilize Low Grade Coals in Italy and Holland

FROM an economic standpoint the war has affected nothing more radically than the relation of supply and demand for fuel. This basic commodity, which has always been more costly abroad than in the United States, has now become fabulously expensive in those countries in Europe that are forced to import coal. Italy and Holland are in this class, although there is a native supply of very inferior coal in both countries. The desirability of utilizing this native fuel is accentuated by the fact that each of the European countries, as a result of the lessons taught by the great conflict, is more anxious than ever to become independent of outside sources for its basic commodities. This applies particularly to coal, and for matters of diplomatic policy alone, both Italy and Holland find ample incentive for undertaking expenditures for special equipment that would enable them to utilize the coal available within their borders. In this connection it was thought that pulverizing as a means for utilizing native low grade coals was worthy of a trial and the results will be watched with unusual interest in the United States, where enormous deposits of lignite coal are lying untouched. Barring consideration of any higher efficiencies that may obtain with the consumption of fuel in a pulverized form, the fact that it may render available relatively inexpensive fuels that can now be mined directly tributary to many railroads warrants the most serious consideration in a country where there will probably never be any necessity to import basic commodities.

It is highly complimentary to American manufacturing enterprise that after making a thorough investigation of the field, the engineers from both the Italian and the Netherland State Railways selected coal pulverizing and pulverized coal burning equipment developed and manufactured by the Fuller Engineering Company of Allentown, Pa.

Lignite Coal Available in Italy

The Italian State Railways have had to depend entirely on imported coal for locomotive fuel, which is now costing them about \$34 a ton in United States currency. The native coal in Italy is a very low grade fuel and unsuitable for hand-fired locomotives. It is largely in the form of lignite and this has led the State Railways to equip two of their new heavy Consolidation type locomotives for burning pulverized coal, as it is thought that this grade coal can be burned in a pulverized form.

There are a great number of lignite coal mines in Italy, the largest of which has an annual output of nearly 1,000,000

tons. These mines are located in several different parts of the country and the coal from various localities exhibits a wide range in composition. The following analyses may be taken as representative:

Moisture (determined separately)	25.7	29.2	31.4	6.4	28.6
Volatile	31.1	47.8	46.9	2.4	32.3
Fixed carbon	20.8	36.3	40.8	66.1	58.5
Ash	48.1	15.9	12.4	31.5	9.2
B. t u. (dry basis)	4,918	8,977	9,072	9,337	11,606

The last of an order of 150 Consolidation type locomotives for the Italian State Railways was being completed in the shops of the American Locomotive Company at Schenectady, N. Y., when it was decided to apply pulverized coal burning equipment to two of these locomotives. The order was placed with the Fuller Engineering Company and was completed in less than 60 days from the date of order. The locomotives were tested out with pulverized coal (about 10 tons being consumed on the two locomotives), knocked down and shipped to Italy.

Description of Locomotives

The locomotives have the following specifications:

Cylinders	21¼ in. by 27½ in.
Steam pressure	170.6 lb. per sq. in.
Drivers, diameter	54 in.
Weight on drivers	131,500 lb.
Total weight	148,000 lb.
Grate area	34½ sq. ft.
Maximum tractive effort	33,400 lb.
Heating surface:	
Tubes	1,331 sq. ft.
Flues	485 sq. ft.
Firebox	117 sq. ft.
Superheater	407 sq. ft.
Water capacity	5,900 gal.
Fuel capacity	10 metric tons
Wheel base, engine and tender	55 ft. 3-1/16 in.

Practically the only change necessary in the tender was to substitute a U-shaped tank, move the tank bodily on the tender back toward the rear 7 inches in order to better distribute the weight on the front and rear trucks. Due to the compactness of the equipment it was possible to install it without in any way altering the water legs from the standard design of the other tenders, the only change in this respect being that the hand brake handle had to be raised somewhat to allow for clearance. As only one coal plant is to be provided in the initial installation it was of course necessary to provide for a much larger fuel capacity than on the hand fired locomotives, which is the reason for applying a tank holding 10 metric tons. A standard American type of brick arch supported on tubes is placed in this locomotive firebox and the sides of the combustion chamber beneath the firebox proper are bricked

up in a standard manner with air vents controlled by dampers, these all being controlled from the cab on the fireman's side.

Pulverized Coal Equipment

The coal is blown in suspension from the tender to the locomotive through 2 ft. 5 in. dia. flexible hose, and the coal feeder is controlled from the fireman's position in the cab by means of a flexible shaft, the ratio between the minimum and maximum coal feed of 346 per cent being obtained and this ratio is again doubled by throwing in or out either one of the two pairs of feed screws by means of the clutches, which project over the apron within easy reach. Four 4-in. dia. steel feed screws operating in pairs draw the coal from the bottom of the tank to the front of the feeder, where it is met by the air from a steam turbine driven fan and blown into the firebox. The feed screws are driven by a two-cylinder, double acting reciprocating engine, enabling the widest variation to be obtained with the minimum steam consumption at all times. A feature of this equipment is that the screws can be started up and operated on 25 pounds of steam pressure. This is a great advantage when it is considered that very often the pressure in roundhouse firing up lines drops to 30 pounds. Due to the screws being operated in pairs, it is impossible for the coal to arch over at any time and a steady constant feed is obtained at all times, no matter how heavy the coal or how long it has been in the tank.

At the same time the order was placed for the locomotives a pulverizing plant was also ordered from the Fuller Company to consist of two standard 42-in. screen type Fuller-Lehigh pulverizing mills having a capacity of approximately 4 tons per hour each, a standard drier, fired by pulverized coal and having an approximate capacity of 10 tons of dried coal per hour. The coal plant throughout is of the standard type with track hopper for receiving the coal from the cars, single roll crusher for crushing it down to the proper size for the pulverizing machines, magnetic separator for removing all tramp iron, etc., and all necessary conveyors, elevators, as well as 40-ton pulverized coal storage bin divided in half, which is placed over the track. Two separate butterfly valves with filling spouts are provided for coaling the locomotives. The plant is driven throughout with electric motors and is equipped with dust collectors, separators, etc., in order to make a clean, dustless, modern plant.

Fuel Situation in Holland

There has been an enormous increase in the cost of fuel imported by Holland for firing locomotives and in order to utilize the cheaper grades and culm piles which have accumulated during many years, the Netherland State Railways have decided to equip two express type passenger locomotives for burning pulverized coal as an initial experimental installation. After a thorough investigation of the subject in their own country and abroad an order was placed with the Fuller Engineering Company in January, 1920, for two complete locomotive equipments as well as a coal pulverizing plant for furnishing these locomotives with pulverized coal.

The coal which is now being hand fired has the following approximate analysis:

Moisture 20 per cent	Ash 7 per cent
Volatile 12 per cent	Sulphur 1 per cent
Fixed carbon 80 per cent		
B. t. u. value, 14,000.			

The coal which it is desired to utilize in pulverized form has the following analysis:

Moisture 4 to 14 per cent	Ash 9 to 15 per cent
Volatile 9 to 24 per cent	Sulphur 1 per cent
Fixed carbon 52 to 74 per cent		
B. t. u. value of this coal, 11,000 to 13,000.			

Locomotives which it has been decided to equip are of the ten-wheel type with four simple high pressure cylinders in the same plane, two outside of the frame and two inside.

The specifications of the locomotive follow: Cylinders, 15 $\frac{3}{4}$ -in. by 26 in.; steam pressure, 170 lb. per sq. in.; drivers, 73 in. dia.; weight on drivers, 96,000 lb.; total weight, 140,000 lb.; firebox, 110 $\frac{7}{16}$ in. by 39 $\frac{7}{8}$ in.

A unique feature of this locomotive, and one which will make it particularly adaptable to pulverized coal, is that on account of having four high pressure cylinders there will be eight exhausts for each revolution of the drivers, which will of course produce a much more even draft through the tubes and firebox.

Description of Equipment

Equipments which will be installed are duplicates, with a few improvements and alterations, of the ones furnished to the Italian State Railways and are also very similar to the one which has been in use on a Lehigh Valley locomotive for the past year, burning mixtures of anthracite silt and

Interior Cab, Italian State Railway Locomotive

bituminous coal with success. The coal plant will contain two 33-in screen type pulverizers, an indirect pulverized coal fired drier with all necessary motors, elevators, dust collectors, etc., to make a complete and modern plant in every detail.

The coal will be received direct into a track hopper from the car and will be crushed down to standard size for the pulverizing mills and delivered to a 20 ton storage tank for coaling the locomotives over a track adjacent to the pulverizing building. The operation will be continuous and entirely mechanical from the time the coal leaves the cars until it is placed in the storage tank over the track. The tank in which the pulverized coal is carried will hold 8 tons of pulverized coal, enabling a round trip to be made with only one fueling. No changes in the outside arrangement of the tender whatever are made, thus enabling the water to be taken as at the present time, at any place along either side of the tender, in the troughs provided, as this is standard practice on the Netherland Railroads. The locomotive will have a brick arch supported on lugs, as it is now standard practice in Holland.

Due to the difference in cost of the coals which they are now burning and which they intend to burn, it is calculated that the whole investment can be paid for in one year, due to the savings resulting therefrom, and it is the intention of the company working the Netherland State Railways to extend the application of pulverized coal burning equipment to other locomotives of suitable size and type as soon as the two which are now ordered have been in operation long enough to determine how much these savings amount to.

BETTER FOUNDATION BRAKE GEAR AND AUTOMATIC ADJUSTMENT NEEDED

BY W. H. SAUVAGE

The use of automatic slack adjusters on electric equipment is becoming general throughout the country. On steam railroads spasmodic attempts to use these devices have been made for several decades. Perfect regulation when made by hand is ideal, but human agency is not dependable. In order to obtain perfect adjustment of the brakes the first requisite is to have a satisfactory foundation brake gear. In recent years more attention has been paid to getting a stronger and less flexible gear than in the past; however, the roads have not departed from first principles in simplifying the foundation brake gear to any appreciable extent. It is true that the roads are gradually retiring outside hung brakes and generally adopting the more reliable inside hung brake, with the brake beam hangers so attached as to prevent their deflection on the wheels, whether cars are empty or loaded, so that more uniform piston travel and brake chain take-up becomes possible.

While this improvement has been in the right direction it should never stop there. Pullman and electric cars have all truck levers standing vertically along the center line of the truck, thus producing as nearly as possible 100 per cent efficiency. This, however, is not the case with freight car equipment or locomotive tender trucks; without any exceptions all car trucks still use truck levers set at an angle of 40 deg., which necessitates a right and left brake beam for every truck. A few years ago a more simple, compact, and reliable brake gear with all truck levers vertical was introduced. This arrangement does not require right and left brake beams, making every beam interchangeable, or by using a reversible strut it allows the use of levers set at a 40-deg. angle when so desired.

This simplified foundation brake gear does away with four clevises, two lever fulcrums and two extra floating levers which are required at the present time to get the reverse pull on the truck levers on opposite ends of the car. The cylinder levers remain of equal dimensions as before, the pull rods are attached thereto in the center line of the car to the truck levers direct; in this manner they do not interfere with hopper bottom arrangements. Providing this direct connection, thus eliminating the extra floating levers and guides, reduces friction to a minimum, making both the power and hand brakes more efficient than under the old arrangement. Brakes release more promptly, preventing unnecessary brake

shoe drag, which reduces the tractive effort of a locomotive often as much as 20 per cent.

When brakes with a modern gear require adjustment, conditions will immediately be improved, whether made manually or automatically. Manually adjusted brakes we are all quite familiar with, but we are not yet fully convinced of the advantages of automatic adjustment. Many automatic devices for adjusting brakes have been brought out from time to time during the last 25 years and some have shown a great deal of merit. Simplicity is the first requirement for an automatic device, next reliability, while durability is essential, especially for freight car equipment.

Let us analyze what it means to have ideal adjustment of brakes on freight cars. Dragging brakes consume a great deal of energy, limiting the hauling power of the locomotive, consuming more or less unnecessary fuel, delaying movements of trains from point to point and causing improper air brake performance. This is primarily due to brakes being adjusted too tight against the wheels. Frequently cars have long piston travel and yet the brakes are found dragging. This is not always entirely due to improper foundation brake gear, but more often arises from the methods employed by the man who adjusts the brakes. In any freight yard when the inspector finds a car with long piston travel he takes advantage of shortening this travel under the end of a car which seems to require the least labor to take up the slack. As a rule he does not go to the trouble to take up or let out the false piston travel on the truck that needs it most, but gets under the easiest end and pulls up the dead lever as far as it will go, and usually manages to get the travel within a few inches of what he wanted it to be. If it is a little long or a little short doesn't matter, to obtain the exact piston travel he desires would require considerable time, so he lets it alone. What the inspector should have done was to balance up the levers on each truck and not allow the shoes on one brake beam to stand away several inches off the wheel on one truck, with the shoes tight against the wheels on the other truck. To do this properly it would probably be necessary to take up slack on the bottom rod connection, but that means more work, and he follows along the lines of least resistance, which is human nature. To get absolutely perfect adjustment is a slow process. The time required to properly adjust brakes on a 100-car train to some predetermined piston travel is often serious and leads to expensive delays aside from the labor involved.

What does it mean to have a train of cars running over

the road or in classification or hump yards with imperfectly adjusted brakes? In the first place the brake gear is the fundamental foundation upon which rests all the good or evil results to be obtained by the use of the air brake. The air brake mechanism is only the governable power appliance attached to the foundation brake gear. Without a reliable foundation brake gear the brake cylinders and triple valves are inefficient. In order to get a perfect air or hand brake control it is necessary to commence at the foundation brake gear; with that in first-class condition the air brake and hand brake mechanism can produce the results they are intended for—to stop or control a train under all circumstances. It would seem almost a criminal expense to operate any power or hand brake with improper adjustment. With the present unsettled labor conditions the improvement so much needed in order to obtain better brake regulation by manual labor seems to be more remote than ever before.

Damage to cars and lading, one of the greatest of all losses in the operation of railroads, can by concerted efforts be gradually eliminated by introducing automatic devices for regulation of the brakes.

It is needless to enter into details of the vast amount of property and injury losses occurring every day, both to trains running over the road and cars switched around terminals and yards. Recently an officer of one of the large eastern railroads reported that in the first week in April, 1915, the lading damage alone on his road ran into five figures, and during the first week in April, 1920, it increased to 29 times the amount in 1915. The damage to property outside of lading is another matter for which some staggering figures could be shown no doubt. Probably poor brakes have a great deal to do with it. Much damage to lading occurs in classification and hump yards. Improperly adjusted brakes permit long brake chains, which also mean long piston travel, producing a bad acting air brake and at the same time an unreliable hand brake, their efficiency having been reduced in this manner in many cases as much as 75 per cent, so that the men who are riding these cars are unable to control them with the braking power on a loaded car often as low as eight per cent. Cars with bad brakes go down the hump striking cars standing still at high speed, which causes most of the damage which occurs both to rolling stock and lading, due to improperly adjusted brakes.

When the trains are running over the road with all kinds of piston travel and all kinds of lading these conditions will invariably produce shocks often as great and more destructive than those done by single cars bumping into each other in hump yards. That this is the truth cannot very well be disputed, so that the only way to remedy this defect is to insure uniform predetermined piston travel, allowing every brake cylinder to do the same work in the same time, both in applying and releasing. Short travel develops high pressure quickly and long travel low pressure very slowly, and here is where the evil arises. There never can be more than one safe remedy to overcome this property and damage loss—that is to insure that very brake cylinder piston travel be automatically regulated to one common standard.

We have relied for 50 years on human agency. Has not the time now arrived when it would be advisable to begin the employment of an automatic device and see if this most vital problem cannot be better solved in this manner?

WHAT A LOCOMOTIVE COSTS EACH DAY.—According to a computation made by the Emerson engineering organization, each railroad locomotive in the United States costs \$84.31 a day more to operate than the revenue it yields in return. In the Eastern section, according to this computation, the daily operating cost averages \$296.63, and the revenue \$206.37. In the South the operating figure averages \$292.82, and the revenue \$208.60.—*Erie Railroad Magazine*.

DROP LOOPS TO SUPPORT STAKES INSIDE GONDOLA CARS

BY W. J. KNOX

Mechanical Engineer, Buffalo, Rochester & Pittsburgh

Railroad gondola cars are used principally for the transportation of coarse and bulky freight, such as pig iron, steel billets, lumber, pipe, structural work, etc. When loaded with lumber, pipe, poles and similar materials, which extend above the top of the sides and ends, it is necessary to provide temporary stakes, and this type of car is equipped with permanent stake pockets at either the outside or inside face of the side walls.

For cars with wooden sides the construction usually permits application of the pockets to the outside, while for steel sides the pockets are at the inside of the car. Placing the usual rigid stake pockets at the inside has been found undesirable because they are bent and broken and rendered useless by ladings of billets, pig iron and other heavy and bulky commodities and shifting loads.

To overcome this trouble a number of so-called collapsible stake pockets have been designed. These are supported at

Drop Loop Stake Supporter

the inside of the car by some form of hinge, and when dropped and out of use the projection from the side wall is decreased and to some extent the hazard of damage is lessened, but by no means prevented. By the arrangement represented by the drawing, when the drop stake pocket is not in use supporting a stake at the inside of the car, it hangs suspended at the outside without projection of any kind at the inside, and therefore cannot be damaged by the lading.

Referring to the illustration, at a position where it is desired to locate a stake, a slot 1, a little larger than the over-all width and thickness of the loop 2, is cut through the side sheet of the car, and over this, with the loop in place, is riveted the supporting bracket 3. The full lines indicate the position the loop occupies and how it is carried by the bracket when employed to support a stake. When the stake is removed the loop is slid through the slot to the outside of the car and hangs suspended from the bracket in the position shown by dotted lines.

NON-COKING COALS.—Experiments conducted at the University of Illinois on low temperature carbonizing of coal indicate that the so-called non-coking coals of Illinois may be advanced one of these days into the class of coking coals. Working at 750 deg. C., the gas produced was high in calorific value; the tars were of unusual interest.—*Scientific American*.

THE BEAHM AUTOMATIC TRAIN PIPE CONNECTOR

Principal Features Are Pin and Funnel Alining Device and Provision for Coupling to Air and Steam Hose

AN automatic connector for train pipes, which embodies several interesting features, including a unique method of interchange with cars having standard steam and air hose, has been developed by Peter Beahm, Altoona, Pa., and was applied for test purposes under the direction of the Railroad Administration. The connector differs from other types in the gathering arrangement, in the method of attachment to the coupler and in the means employed for coupling to cars not equipped with connectors.

The connectors on adjacent cars are alined by means of a pin on the horizontal center line of the connector and some distance to one side, and a funnel on the opposite side

arm of the coupler by a set screw. The rear portion of the frame consists of a bracket provided with two vertical slotted plates. This bracket supports the main connector frame, which is provided with slotted projections having teeth to engage the bracket of the main frame. Thus the height of the connection can be adjusted independently of the coupler.

The main connector frame has two parallel horizontal members which terminate in a yoke having a boss at the center to receive the rear end of a coiled spring. The vertical guiding stem carrying the connector head fits in a slot in the upper portion of the frame and the carriage for the connector, which contains the gathering device and the parts,

Cars Equipped With Beahm Connector Coupled Together

having a rectangular opening leading to a central cylindrical opening. The funnels guide the pins so that the cylindrical end of the pin will enter the bore of the funnel. The ports in the connector are so located that they come into contact just before the couplers close and are held to their seats by the compression of coiled springs.

The bracket supporting the connector spans the head of the coupler and is held in place by a long knuckle pin. The bracket is so arranged that in case the pin breaks it is still held in position and the connector cannot fall to the track. The supporting bracket also carries an arm, on the end of which is a shoe, the shoe being clamped against the guard

slides upon the lower frame member. On the rear face of the carriage is a socket into which fits a knob carried in the outer end of the coiled spring, which extends to the rear of the yoke. The spring holds the carriage at the forward end of the yoke, where its travel is stopped by the stem engaging the outer end of the slots. The socket and boss are offset slightly from the center line of the carriage and the form of the slot is such that pressure of the spring will hold the connector ports either on the center line of the car coupler or at a position approximately at right angles to the center line. The carriage is provided with three channels, the center one terminating in the air brake supply port, the

others leading to the upper air signal port and the lower steam heat port, all three being in the same vertical plane. On the ends of the carriage opposite the air brake and signal ports are lips provided with recesses for receiving the lugs of the standard air and signal hose couplings.

The channel for the air brake connection leads to the rear of the carriage, where it enters a vertical passage, which is closed at the upper end by a plug, while the lower end carries the condensation valve. This port is also connected by horizontal and vertical ball jointed pipes to the air

Plan of Connector Carriage Showing Method of Attaching Air Hose and Two Positions of Spring

brake line. The air signal pipe connections are similar to the air brake connections, except that no condensation valve is provided.

The steam heat connection is carried on the opposite side from the signal connection. A vertical pipe from the carriage leads to the condensation outlet valve and a casing having a hole for the reception of a plug cock and an outlet through the cock, which is connected to the steam heat line by flexible jointed pipes similar to the air brake and signal connections. The plug cock in the steam inlet casing carries a standard steam heat coupling, which is connected to a

End Elevation of Connector Showing Piping Arrangement

port in the key. When the cock is in the normal position and the carriage is in line to couple with connector-equipped cars, the steam passes through the cut-away portion of the cock directly to the port. In this position no steam can pass out of the steam hose coupling and it is held in place by a link attached to an arm on the steam pipe connection. When the connector is used with the ordinary form of coupler the coupling and the cock are turned through a half circle, when the port assumes a position that prevents the steam escaping to the port in the face of the carriage and opens a passage from the steam line through the steam

hose coupling. The carriage can then be turned at right angles to the coupler center line, thus allowing air brake and signal hose to be connected to the respective ports.

A special feature of the connector ports is the metal coupling ring which is provided with several concentric grooves.

Position of Parts When Coupled to Car Having Standard Hose Connections

In case dirt lodges upon the smooth portion of the ring the action of the opposing connector will cause it to be rubbed into the grooves, thereby eliminating leakage.

The connector, as will be noted, provides a complete metallic connection throughout the train. The joints in the carriage and the pipes are formed by removable seats into which are

Details of Connections to Coupler Carriage

seated hemispherical joints having a limited angular movement. These joints have no packing and are kept tight by the weight of the attached parts and the pressure acting upon them. This form of joint is an earlier invention of the originator of the coupler.

THE INSPECTION OF FREIGHT EQUIPMENT

Handling Weak and Defective Cars. Preparing Equipment for Refrigerator and Heater Service

By L. K. SILLCOX

General Superintendent Motive Power, Chicago, Milwaukee and St. Paul

It has been found that bad-order cards on cars are sometimes removed by malicious persons and in some instances have been washed off by heavy rain. In order to overcome the embarrassment caused by the cards being removed, inspectors will arrange hereafter not only to card the cars, but also to mark them on both sides with chalk.

If a car has penalty defects or other safety appliance defects it should read "Bad Order, Safety Appliance Defects, Steps Missing," etc., or in case of defective draft gear, sills, etc., it should read "Bad Order, Handle With Care." These markings should appear on both sides of the car, so that there will be no opportunity for switchmen or trainmen to claim that the cars were not marked bad order.

Switching Defective Cars

Defective freight cars should not be switched in with good serviceable cars, in order to avoid damage to the serviceable cars. When defective freight cars are shopped out in the transportation yard, they should be placed on tracks designated for such cars, avoiding frequent handling of the defective cars and preventing further damage.

Location of Cars in Trains

Section 988 of Standard Rules and Regulations of the Operating Department reads as follows:

"The following cars, loaded or empty, will be handled next ahead of the caboose, giving preference in the order shown, except that at least one car must be handled between a flat car loaded with rails and the caboose. 1. Bad order cars; 2. Bunk cars; 3. All wooden flat cars; 4. Coal cars with temporary sides; 5. Oil and water tanks, except all steel or steel underframes.

"In addition to this, loaded or empty cars of 40 tons capacity or less with short draft timbers should be switched to the rear end of trains."

Switching Wooden Cars to Rear of Train

Car inspectors will mark all cars with short draft timbers for switching to the rear of the train when loaded and empty, provided they are to operate in trains of 65 cars or over. Car inspectors must be instructed to chalk-mark all cars with short draft timbers suitably on both sides, in plain legible writing stating whether they are to be switched to the rear, and if a load, marking them to be cut out when empty, besides taking down the car number and the date. All concerned must co-operate to see that cars are properly loaded to avoid embarrassment in service.

Switching Weak Cars

In cases where short draft timber cars are placed in long trains, and experience has dictated a policy of care, due to characteristics of the line, and it is felt economical to switch out weak constructed and equipment with short draft timbers to rear of train, this should be done. As a general plan, no train containing 65 cars or more should have cars with short draft timbers placed except at the rear. Cars which are to be switched to the rear will have the initials W. C. six inches high placed on the side of the car above each transom, this standing for weak construction.

Icing Refrigerator Cars

Standard Rules Regarding Re-Icing of Cars Containing Meats, Packing House Products, etc.:—The following rules must be observed:

For straight or mixed cars of fresh and frozen meat or dressed poultry, use crushed ice with salt.

Packing House Products:—Butter, eggs or cheese must be re-iced with crushed block or lump ice, with or without salt in accordance with railroad billing.

1. Quantity and preparation of ice, and grade of salt: Ice must be thoroughly cleaned by flushing with water, thus removing all foreign substances to prevent clogging of drains.

Description of Crushed Ice: Ice should be no larger than a man's fist.

Description of block ice: Ice should be broken in chunks weighing approximately 50 lb. and permitted to fall into tanks loosely.

Description of lump ice: Ice should be broken in chunks of 15 or 20 lb. When the railroad billing specifies the use of salt, follow the salting method described in paragraph four below.

Description of Salt: No. 2 rock salt must be used in accordance with instructions on railroad billing. Foremen should anticipate their requirements for salt sufficient in advance to insure an adequate supply.

2. Hatch covers and plugs removed: Extreme care must be used in the removal of hatch covers and plugs to prevent all foreign substances from dropping into tanks. Uncover only such tanks as can be immediately filled to prevent any unnecessary exposure. Plugs and covers are to be replaced at once after re-icing is completed. Plugs are to be fitted evenly and tightly in the tanks by lightly tamping with the tamping pole.

3. Release of excess brine: If tank valves do not work, excess water must be removed from tanks before re-icing is attempted. This can be accomplished by using a hand pump or bailing out with buckets; if the valves do not work, the next icing station must be notified by wire so that they can be prepared to remove promptly the excess brine before re-icing.

The A. R. A. Rules of Interchange, rule 3, paragraph f, require all beef refrigerator cars to be equipped with brine retaining valves to prevent brine dripping along the right of way between icing stations. When the plugs are pulled, excess brine is automatically released. Considering the large number of cars now equipped with this device, and the rule requiring all such cars to be equipped as fast as possible, it is necessary that each icing station procure a hand pump. Excess brine must be removed from the tank before re-icing is attempted.

4. Tamping and salting crushed ice: Foremen should see that a wooden tamping pole is used, and under no circumstances should they permit pike poles or poles with metal ends to be used. The tamping pole should be inserted into the old ice which should be thoroughly stirred and tamped to settle it to the bottom of the tank. After tamping, one third of the salt required in the re-icing is to be properly spread over the old ice before any more new ice is used. Then the tanks are to be filled with ice and the balance of the salt evenly spread on top of the new ice. The men icing the cars should again use the tamping pole vigorously to even off the top of the ice and start the salt working. They should see that the space between running boards is filled, but should not fill tanks above the top of the saddles.

5. Stations not equipped with an ice crusher, should secure the necessary wooden mauls and ice crushing boxes to insure efficient re-icing. Under no circumstances should ice be broken on the roofs or in the tanks of cars.

For ready reference the following table can be used to determine the amount of salt in pounds based on the quantity of ice supplied.

Salt Required for Various Percentages and Weights

Ice Pounds.	Five percent salt; lb.	Seven percent salt; lb.	Eight percent salt; lb.	Ten percent salt; lb.	Twelve percent salt; lb.	Fifteen percent salt; lb.

Preparation of Cars for Heater Service

All ice and inflammable matter must be removed from bunkers and drip pans, all doors and hatches tightly closed. Bulkheads must not be lined with paper when heaters are to be placed in the bunkers. In order to permit circulation of air, the drain pipes should be cleaned and left open before and during the process of loading, as well as while cars are in transit. When cars with ice tanks are used, heaters should be placed in ice bunkers of cars and securely braced.

Charcoal Heaters

When refrigerator cars contain ignited charcoal heaters, placed in ice tanks, the hatches must be left open a few minutes before entering the tanks or bunkers of the car. All persons are warned against remaining in cars with doors or hatches closed while charcoal heaters are burning and to use caution on entering cars under such conditions.

Care of Charcoal Heaters

In selecting and preparing fuel for both the Cole and Baxter types of heaters, charcoal of good quality, absolutely dry, free from knots and reduced to the size of a walnut should be used. The efficiency of the heater depends largely upon using charcoal of proper quality and size. Charcoal dust must not be used in the magazine. Charcoal must be stored where it will keep perfectly dry.

Operation of Cole Heaters

(a) To fill the magazine shove in the cut-off slide and fill the magazine with prepared charcoal, free from dust, as dust will choke down the fire. The cover of the magazine must be kept closed absolutely tight while the heater is burning. This is essential to prevent a draft of air from the fire pot up through the magazine. When it is necessary to open the cover to replenish the charcoal, that must be done quickly and the cover again closed without delay.

(b) In order to start the fire, remove the fire pot and fill it not to exceed 2/3 full of clean charcoal free from dust. Replace the fire pot, remove the starting lamp through the ash pit hand door and saturate with alcohol. Light and replace the starter, then put on the magazine section and lock the heater with the pin. Pull out the slide (secured by

a pin) in the magazine and see that the fuel feeds down and close the ash pit hand door.

(c) In regulating the draft slide, set it either at full heat or slow heat as conditions require. Remember that the fuel always heats up considerably hotter during the first 12 hours with either draft position.

(d) Kerosene or papers can be used in starting the fire, but will cause considerable smoke until burned out. Be sure that the heater has a good start before placing it in the car. The heater can be nailed to the floor, swung from chains from the ceiling of car or anchored in the bunkers of the car by chains. The ash pit door must always be closed except when removing ashes or the starter. The top feed lid must always be closed tight to prevent burning in the magazine. To extinguish the fire, simply remove the pin and shove in the cut-off slide. Remove the ashes at least once a week and never dump them on the car floor nor on wooden platforms or ties. Some ashes retain fire hours after dumping.

Operation of Baxter Heaters

The fire in the heater can be started in the car, but the door or hatches in the car must be left open to give a draft and allow the escape of gas. It is better practice to start heaters on platforms in the open air.

The procedure is as follows: (1) Remove the magazine by unfastening the hasps at the bottom and lifting off. (2) Punch a hole in the center of the paper starter and light there, then place on the grate in the bottom of the fire pot and put three or four handfuls of charcoal or briquets on the starter and let it burn a few minutes. (3) Fill the fire pot and let the blaze show before putting on the magazine. This will usually take about ten minutes. (4) Put on the magazine and fasten the hasps at the bottom, then remove and fill the cover, shaking a little to fill to capacity. Replace the cover quickly and see that it is on tight. Do not use charcoal dust in the magazine. If the heater has a shut off slide, pull it out and place a pin to keep it open.

Handling Road Work

Men doing road work often cannot get into their home station without making unavoidable overtime, due to lack of convenient train service. There is only one means to resort to in combating this condition, namely to see that where men lay over at any station, they take it upon themselves to go over any cars which are located adjacent or within easy reach of the car which they repaired, giving them such necessary attention as to fit them for service, besides making every adequate repair within their power to the cars which they were sent out to take care of. Good judgment is necessary and roadmen should be checked up to see how many work cards they deliver showing actual repairs made. They should carry sufficient cotter keys, nuts, small bolts and other items with them so as to provide for any eventuality. In any case, they can take care of the packing on a number of cars without additional material, all of which should be properly reported. All supervisors should interest themselves to the extent of seeing that this matter is followed up from day to day. There is always a proportion of the expense chargeable to transportation accounts, namely, that spent in the attention given oiling and packing of boxes, closing side doors, classifying cars for various loading, etc.; of course, the time actually spent repairing the equipment is chargeable to car repairs.

It is not proper to send men out on the road to repair cars with broken train lines, defective air brake equipment, framing or truck members, if it is at all possible to get the car safely to some repair station by hauling it behind the caboose, care being exercised, of course, to see that loaded cars are not delayed unnecessarily and back-hauled too greatly in case there are no means available for turning the car.

Latest Type Pullman Sleeping Car

IMPROVEMENTS IN NEW PULLMAN SLEEPERS

Changes in Details Which Have Been Developed to Add to the Comfort and the Safety of Travel

ALTHOUGH no changes in basic design have recently been made in its equipment, the Pullman Company has been constantly working on the development of detail improvements most of which have had for their object an increase in the comfort or safety of the occupants of Pullman accommodations. A number of changes of this na-

In the new cars both the upper and lower diaphragm buffer mechanisms have been arranged to maintain the alignment of the diaphragm within the limits of the clearance in the pocket, thus eliminating the greatest source of noise at the ends of the car. In this design provision has been made to take up wear so that the diaphragm may be readily

Section Through the Lower Buffer Side Stem, Showing Wear Adjusting Screw and Wedge

ture have been incorporated in the new sleeping cars which the company has been building at its Pullman works, Chicago, since the return of the railroads to private operation.

Diaphragm Mechanism

The metal diaphragm is now a standard feature of Pullman car construction and cars equipped with these diaphragms have been in service several years. The clearance between the diaphragm and the sides of the narrow metal pocket within which it telescopes is necessarily limited. But the method by which these diaphragms have been supported has permitted considerable lateral motion at the top and this has tended to increase rapidly as the buffer side stems wear into the surfaces of the openings in the platform end casting through which they pass. These conditions have resulted in the constant slamming of the diaphragm against the sides of the pocket and the noise thus caused led to numerous complaints.

restored to its normal position as frequently as conditions require.

The height of the diaphragm is controlled by the surfaces on which the buffer side stems rest. In the new cars these stems are supported on adjustable shims or wedge blocks let into the platform end casting and adjusted as shown on one of the drawings. The adjusting device consists of three pieces, the shim, the adjusting screw and the nut. The parts are readily assembled or removed by turning back the adjusting screw into the nut, which permits the nut to be inserted or lifted out of the opening in the casting. The shim is then free to drop out. When properly adjusted the screw is prevented from turning back by a cotter which passes through slots in the extended portion of the nut and one of two holes drilled through the screw at right angles to each other.

Upper diaphragm buffers either of the semi-elliptic spring type or of the stem and coil spring type have never pro-

Single Stem Diaphragm Mechanism With Babbitted Center Plates

Ventilator Applied to Lower Rail of Outside Sash

vided a satisfactory means of centering the top of the diaphragm. Consequently the entire reaction from the lateral force at the top of the diaphragm caused by the swaying of the cars has been taken by the buffer side stem supports. This has caused excessive wear and a rapid increase in the lateral movement at the top of the diaphragm.

To overcome this a single stem upper diaphragm mechanism has been designed in which the stem is restrained between lateral bearings where it emerges from the end of the car. These bearings are removable malleable iron castings faced with babbitt, inserted from the outside and held in

Locked Center Pin With Full Diameter Effective for Stress Resistance

place by machine screws applied through flanges to the end of the ear. When worn they are readily replaced, and after rebabbiting are ready for further service. The buffer stem rear guard is also lined with babbitt, but this casting is riveted in place and is not designed for removal between shoppings.

Sash Ventilators for Lower Berths

Although an extremely simple device, the sash ventilator which has been placed in the lower rail of the outer or storm sash of the car windows is one which immediately appeals to the occupants of lower berths and it has already been the object of a number of individual expressions of appreciation from the traveling public.

The difficulty in always securing satisfactory ventilation and temperature regulation in lower berths during the seasons when heat is required and the windows are normally kept closed is well known. Under these conditions the only recourse of the occupant of a lower berth who wishes additional ventilation is to raise the inner sash and then slightly open the outer sash, adapting some portion of his personal belongings to serve as a stop to prevent it from working shut. The ventilator furnishes a screen protected opening,

closed with a horizontally operating slide, which provides easy and close regulation of the amount of air admitted.

The Locked Truck Center Pin

While it is impossible to design equipment strong enough to resist destruction under all conditions of collision impact, it is generally recognized that anything which will tend to hold the underframes in the same horizontal plane will exert a powerful influence in the prevention of telescoping, the form of destruction usually responsible for the greatest loss of life in train accidents.

The use of a locked center pin as a means of resisting the tendency of one underframe to climb over the top of another has received considerable recognition and at least one self-locking center pin has been developed. The locked center pin is effective only so long as it holds the truck and car body together. The self-locking type is open to the possible objection that the full area of the pin section is not available to resist tension or shearing stresses and therefore under certain conditions might not be as effective in preventing a separation of the truck and car body as a pin of solid section.

These considerations have led to the design of the center

Built-Up Pedestal for Pullman Trucks

pin shown in one of the drawings. The pin is a forged steel bolt four inches in diameter with a shallow hexagonal head and a square nut of special design. The head sets in a shallow hexagonal socket at the bottom of a pocket in the center sill filler casting. The nut is placed in a square recess in the under side of the truck bolster and two 7/8-in. bolts applied through flanges of the bolster casting hold it in position when the center pin is not in place. In applying the bolt it is dropped in place and screwed into the nut,

which is held in sufficiently close alinement by the square recess in which it is placed to prevent any difficulty in starting the threads. When drawn up as far as it is possible to turn the bolt, the head is brought into register with the socket and dropped in. This locks the bolt and nut except for the slight turning of the nut due to the curving of the trucks, which it is expected will prevent the nut from sticking and causing trouble when removal is necessary.

The use of check chains has been dispensed with and a plate on which is cast in raised letters the legend, "Locked Center Pin, Remove From Inside," is attached to both side frames of each truck between the center and inner pairs of wheels.

Built Up Truck Pedestals

In order to overcome the occasional failures of cast truck pedestals which have occurred in service a pedestal built up of plate and rolled and flanged sections has been designed and applied to the new equipment now being built. The outside and inside plates are of 3/4-in. and 1/2-in. open hearth steel, respectively, and are separated by steel pressings at the top and bottom. The top pressing is of one-half inch

Application of Safety Chains With Spring Washers

material and is electrically wedged and riveted in place. The lower pressing is of 3/8-in. material. The jaw faces are formed by two rolled steel pieces of special angle section which are riveted to the outside of the plates with the short legs turned in. These pedestals are built up and applied as units.

Safety Chain Application

One of the interesting details in the construction of these cars is the use of spring washers on the safety chain anchor bolts. The application is shown in detail in one of the drawings. The washers are 6 in. in diameter and are cupped to a depth of 5/32 in., each, thus providing for a full load travel of the safety chain bolt of 5/8 in. This arrangement, which is common in European practice, acts as a cushion for part of the shock to which the chain and bolt are subjected when brought into action by a failure of the coupler. In the application shown these washers have a full load capacity in the 5/8 in. travel of approximately 50,000 lb.

PREPARATION AND APPLICATION OF JOURNAL BOX PACKING

BY NORMAN McCLEOD

The arrangement for soaking oil is an important adjunct to all modern oil houses. The drawings accompanying this article show three designs of cans and boxes or tanks for soaking and draining the packing, each having its peculiar advantages. The plain box, Fig. 1, and cans shown in Fig. 2, are in extensive use and are satisfactory for properly soaking and draining the packing for cars and locomotives, but are more or less crude in comparison with the method shown in Fig. 3. With equipment shown in Fig. 1 the packing must be handled from soaking compartment

Fig. 1—Soaking Tanks With Portable Draining Boxes

to drainage tray, which becomes a more or less untidy operation, but with the cans, Fig. 2, and vat system, Fig. 3, it is not necessary to handle the packing, except to take it out when it is to be used, as it is soaked and drained in the same compartment.

In Fig. 1 it will be noticed that the soaking tanks are made up of three compartments of a size to meet local requirements, the oil being conveyed to them from the oil storage tanks by pressure or by pump, as desired. Provision is made for a portable tank or box on wheels, as shown in Fig. 1, to facilitate its movement over the various compartments. The bottom of this portable box should be made of a suitable screen, strong enough to sustain the weight of the oil soaked waste. The size of the box as shown is 20 in., by 3 ft. 8 in., by 4 ft. 0 in. This, of course, as well as the size of the soaking tanks, depends on local requirements.

Fig. 2—Arrangement for Soaking and Draining Packing Without Removing from Cans

The arrangement shown in Fig. 2 represents a step in advance of that just described, in that the tanks or cans are separated and are provided with a screen three inches from the bottom of the can, to which the oil returns after percolating through the waste, to be drawn off into an inclined trough by which the excess oil finally reaches an auxiliary tank, shown in dotted lines in the front elevation. If desired, this tank can be provided with a vertical graduated scale, thus allowing a check to be kept of the amount of oil absorbed. Provision is made in this plan for the return of the oil from the auxiliary tank to the soaking tanks by the use of a rotary pump as shown.

In Fig. 3 is shown a more advanced type of apparatus for this purpose, which allows of greater rapidity in soaking

and pressing out all surplus oil, the pressing being done by a portable air cylinder, or by hand power if air is not available. The cylinder is arranged to travel over all the vats, as outlined in the drawing. Each vat is provided with a perforated bottom placed six inches from the base. From this space the oil is drawn through faucets as shown. Provision is made for the oil, which naturally accumulates above the pressing plate, to reach the oil space below, by having three-inch galvanized iron strips, perforated the full length, placed in each corner of the vat as is clearly shown in the plan view.

Each vat should be provided with a scale of gallons so that the amount of oil used may be known if desired. This latter plan is the best for large car receiving and repair yards, and has been used for some time and with most satisfactory results on a number of important western railroads. The arrangement has many advantages and is worthy of consideration for all important oil houses.

The way in which the work is handled has an important bearing on the results secured, regardless of the equipment or the materials used. The method of packing boxes described below and the tools illustrated have proved effective in securing the best results in lubricating cars and locomotives.

Preparation of Sponging or Packing.—The waste must be separated in small quantities, but never rolled in bunches and must not be cut. It must then be submerged in freight or coach oil, according to requirements not less than 48 hours and kept submerged in oil until used. Before using, the surplus oil must be drained off, allowing a sufficient amount to remain, which is approximately equal to three pounds of oil to one pound of waste for freight cars and

apart and again used for packing purposes. In no case should valve oil be used to saturate waste for packing purposes.

Method of Packing Journal Boxes.—All extra oil should be wrung or pressed out of a portion of waste, forming it

Fig. 4—Arrangement of Water in a Box Properly Packed

into a loose rope. This should be packed tightly around the back end of the box, to assist the dust guard in retaining oil in the box and in excluding as much dirt as possible. The box should then be packed with loosely formed

Fig. 3—Tanks Equipped with Press for Preparing Journal Box Packing

tenders, and three and a half pounds of oil to one pound of waste for passenger cars. The sparging while being used, must either be turned over periodically in the tank or the oil raised from the bottom of the tank and poured over the top of the sparging to keep all of the waste and oil in the tank properly mixed for use. Old sparging removed from locomotives and cars should be examined and the waste found in good condition should be cleaned, picked

portions of the sparging to insure holding it in contact with the journal, being careful not to set it above the center line of the journal. The packing should not be entered between the journal and the side of the box, but should be entered directly under the front of the journal. This packing should extend well out to the front of the journal, as shown in Fig. 4, and should be packed back of the collar.

The sparging between the end of the journal and the in-

side front face of the box should have no connection with the sponging under or on the sides of the journal, as this sponging affords no means of lubrication to the journal, but is simply to prevent the sponging under the journal working out of position. For passenger and locomotive tender journal boxes the sponging between the end of the journal and the inside front face of the box should be formed of waste in the shape of plugs wound with cord, in order to facilitate their removal for the purpose of examination and setting up of packing.

When old sponging is reclaimed sufficient oil should be added to bring it to the same degree of saturation that is required for new waste.

Figs. 5 and 6 represent a variety of steel packing tools for use in packing car and locomotive tender journal boxes. Nos. 1 and 2 are for use in shops and car repair yards, where this work principally consists of the entire repacking of boxes. Tools 3, 4 and 5 are assigned and extensively used for the proper care and treatment of packing by oilers or inspectors in yards or cars in transit.

Two designs are shown, Nos. 3 and 4, which combine

Fig. 5—Efficient Tools for Packing Journal Boxes

the features of Nos. 1 and 2, enabling a man with one tool to either quickly remove surplus packing with the hook edge of the tool, or to loosen the packing on the sides of the box and restore it to its proper position at the rear of the box with the spur edge of the tool. The handles of these tools differ, some preferring the wooden to the metal handle. Tool No. 5 has a V-shaped end and is in very general use in place of tools Nos. 3 and 4. Tool No. 6 has also been found desirable for the treatment of packing boxes.

A tool of either of these designs made of steel, should be used for rapidly and effectively maintaining the packing in an elastic condition and thus avoiding glazing and securing a more rapid flow of oil from the packing to the journal.

Tools Nos. 1 to 6, designated for driving boxes, are used for care of packing in driving box cellars of locomotives,

Fig. 6—Packing Tools for Locomotive Driving Boxes

and have been found very effective. Tool No. 6 is used in removing packing drawn up by the journal and caught by the lower edge of the brass; this tool has been found valuable in enginehouses on locomotives in passenger service.

Salvaging Railway Property in Dublin from Freight Cars Which Were Set on Fire by Irish Incendiaris

HACK SAW BLADES AND CUTTING PRESSURE*

Too Little Pressure on Hack Saw Blades Is as Bad as Too Much; Work Must Be Held Properly

ONE of the most important factors in efficient cutting with a power hack saw machine is the maintenance of the proper pressure on the blade during the whole of a series of cuts. Failure among hack saw users to realize this fact causes big waste of blades and time, a waste far greater than is generally supposed. The maximum efficiency is to be found in the saw that cuts quickest and lasts longest; that combines cutting efficiency with endurance. The ability to cut in the shortest time is but one of three

at 20 lb., and a cut made. The time required for the cut was 35 min. Another blade was then placed in the machine, the pressure increased to 25 lb., and another cut made. The time required was 30 min. With the 30-lb. weight, a new saw completed the first cut in about 24 min. Another saw was inserted, the weight increased to 40 lb., and the time of the first cut was reduced to 15 min.

Effect of Too Much Pressure

The next increase was to 44 lb., which is the weight recommended for this particular saw, and a new blade made its first cut in 11 min. 30 sec., which is slightly better than a good average time for a first cut on this size and class of material. The weight was then increased to 50 lb., and subsequently, in increments of 10 lb., to 70 lb., a new blade being used each time, and the time of the first cut noted. While the time per cut continued to decrease as the weight increased, the saw in each case was actually cutting at a destructive rate when the weight was increased beyond the amount recommended for that particular blade. Had any of the saws used been tested for the number of cuts per blade and general efficiency, it would have been seen that when the weight rose above 70 lb. in the first cut, the life of the saw was considerably shortened.

While a hack saw must be made to withstand a great amount of abuse, there are limits beyond which it will not go; and where a saw is forced to cut under a greatly excessive weight the gain in time per cut may not offset the loss in saws, spoiled stock, etc. On the other hand, mere endurance without cutting effect, as exemplified in a saw that is worked too "gingerly," does not represent efficiency.

Insufficient Pressure

In a test to determine the results of insufficient pressure, the conditions were exactly opposite to those of the preceding experiment. A weight was applied in each case which was considerably less than that recommended for each particular blade used in the test and the results are shown in Fig. 2. Not only was the time per cut far in excess of what should have been required to cut the class of material on which the test was made, but the life of the saw was decreased almost as rapidly as when too much weight was used. The teeth of the blades were destroyed by slipping and sliding over the work, rather than by cutting.

Fig. 1.—Chart Showing Relation Between Pressure on Blades and Time Required to Make Cuts

objects that determine the value of a hack saw and, when time is only considered of value, the chances for a loss of efficiency are exactly two out of three.

The effect of the regulation of weight on the time per cut is clearly shown in a recent test made to determine the results of various pressures on a number of blades. The test results are shown graphically in Fig. 1. In this experiment a new blade was properly placed in a hack saw machine, a piece of 3-in. machine steel put in the vise, the weight set

*Abstracted from "Hack Saws and Their Use." by the L. S. Starret Company, Athol, Mass.

These results make it evident that using too little pressure is almost as inefficient and costly as using too much, while the practice of using insufficient pressure has not even the doubtful advantage of saving time at the expense of the blade and stock, as is the case where too much pressure is employed. Between these two extremes lies the happy mean which represents the acme of hack saw economy.

The actual pressure in lb. per sq. in. of contact area of the tooth, which has been found to give the most satisfactory results as regards both the time per cut and the number of cuts per saw, varies from 20 to 30 lb. It has been determined by careful tests that pressures within these limits, while not overloading the saw, are sufficient to avoid any possibility of the blade slipping and sliding over the work, and thereby becoming dull without having worked to more than a portion of its rated capacity. It has also been found that the basic weight or pressure is directly proportional to the gage of the saw. Standard practice indicates using the 20-lb. unit of pressure for blades not over 0.040 in. thick, and 25 lb. for saws between 0.040 in., 0.060 in. and over.

This so-called unit or basic pressure must not be confused with the weight actually resting on the blade when in use, but must be taken as a constant, by the use of which the actual pressure on the saw may be calculated. The weight, or pressure, is measured by attaching a spring balance to the forward end of the saw-frame, when the blade is in mid-stroke, and lifting. The amount of pull indicated by the needle of the scale is the weight on the blade.

A workman, using a hand frame, almost instinctively

Fig. 2.—Results of Too Little Pressure on Blades

bears harder upon the blade as the work progresses and the teeth lose their first keenness. This same principle of gradually increasing the pressure after the first few cuts must be applied to the power saw if efficient work is to result. No matter how nearly correct the weight is at the outset after a certain number of cuts have been made, the pressure must be increased, not only for the sake of reducing the time per cut to a point within the limits of efficiency but also to prolong the life of the saw.

Increase Pressure With Number of Cuts

A saw wears as it is used, and the area of the teeth in con-

tact with the work becomes greater as the number of cuts increase, and therefore, in order to maintain the same cutting speed, the pressure must be increased from time to time. It may be taken as a maxim of hack saw thrift that, for efficiency, the weight must be increased as the number of cuts progresses.

In connection with the necessity for the proper adjustment and increase of weight it is interesting to note that equal diameters of work of the same material will be cut at about the same rate, without regard to their comparative shapes. That is, 1½ in. square, round, or elliptical bars of the same grade of steel would cut at the same rate. Angle irons, channels, and tees of the same greatest dimensions, will cut about alike, provided they are properly placed in

Fig. 3.—Proper and Improper Methods of Holding Various Shapes While Being Cut With a Hack Saw

the vise. Proper and improper methods of holding different shapes are illustrated in Fig. 3.

Cutting speed on rounds of any given material increases as the diameter of the work, and varies in the same proportion as the saw goes through any particular cut. Theoretically, the weight during the progress of each cut should vary directly as the diameter of the work, though this is, of course, impracticable. However, it is essentially practical that, when the time required for any single cut becomes greater than the average time required for cutting that particular class of material, with that particular blade, the weight or pressure on the blade should be increased a few pounds before beginning the next cut.

Increase of pressure to compensate for the wear of the blade is absolutely essential to economy in hack saw work, but it is a factor for which no absolute rule can be given. The most that can be said is, knowing approximately the time in which a certain blade should cut an average specimen of a certain kind and size of material, the weight should be increased by increments from 5 to 10 lb. as often as the time of three successive cuts is above the average. The weight on a heavy gage saw must be increased faster, in proportion to the extra amount of dulled surface or contact area, than for a thinner gage saw, regardless of the difference in weights on the first cut with each. In hack sawing, as in any other form of work, common sense, attention to detail and observations of manufacturers' instructions are great assets.

MICROMETER CALIPERS IN RAILWAY SHOPS

Showing How Output is Improved in Quality and Quantity by the More General Use of Micrometers

BY M. H. WILLIAMS

IN 1324 King Edward II of England decreed by statute that, "Three barley-corns round and dry shall be the definition of an inch." The barley-corn days of measuring are long since out of date not only in commercial but also in railway machine shops where the two-foot rule has ceased to be the standard of measurement. Micrometer calipers, now indispensable in railway tool rooms, are coming into more and more common use for general shop work. It may appear at first glance that the refinements possible with micrometers are not necessary for locomotive and car work, which does not as a general rule require the close fitting demanded in some lines of manufacturing. As a means of quick calipering and securing the required degree of accuracy, however, micrometers are invaluable. A large case of instruments used in a modern railway shop is illustrated in

Fig. 1.—Micrometer Calipers Shown in This Case Are Given Out on Checks.

Fig. 1. Common forms of 1-in. outside and adjustable micrometers are shown in Figs. 2 and 3.

Railway shop work being mostly repair work, involves the truing up or re-machining of worn parts and the fitting of new parts. Since it is almost impossible to maintain fixed standards, standard gages can be used only to a limited extent and micrometers will aid in carefully measuring the re-finished pieces and new parts with the required degree of accuracy. An accuracy greater than .001 in. is usually unnecessary except possibly for force fits.

Micrometer Sizes Required

Micrometers generally have a range of one inch and different instruments are required for each one-inch range. In order to cover the range of work common to railway shops, it is desirable to provide both outside and inside micrometers for each size up to 12 in. In addition, inside micrometers should be provided for the larger diameters to be measured, such as locomotive cylinders which will require one for each size of cylinder common to the road. For external diameters greater than 12 in., it is advisable to make use of adjustable

micrometers having a range equaling the largest piston usually handled. The cost of the instruments mentioned, without duplicates, is about \$300. For certain of the more frequently used sizes, it is necessary to provide duplicates that will add to the cost, but the reduced number of spoiled or misfit parts will more than offset the additional expense. Experience in practically all shops where micrometers have been used indicates that workmen will exercise the same care in handling them as a scale or any finished tool and that the cost of upkeep is not a serious consideration. The instru-

Fig. 2.—Common Type of 1-in. Micrometers.

ments are generally a part of the tool room equipment and given out to any man who may have use for them on tool checks, the same as twist drills, taps, reamers, etc. It is good practice to check each instrument to a standard measuring rod when returned.

Shopmen accustomed to machinists' calipers learn to caliper with micrometers in a few days. Regarding errors in readings, it may be well to consider a concrete example. If it is considered satisfactory to continue piston rods in service where the difference in diameter at any two points does not

Fig. 3.—Adjustable Micrometer Calipers.

exceed .001 in., measurements with micrometers will show at once if the rod is within these limits and settle definitely the question of repairs. This measurement, also, will tell if the rod is worn to an unsafe limit. The same measurement made with machinists' calipers takes longer and does not give as certain results. Machinists' calipers must be set for each diameter measured, the same as with micrometers, and in each case be compared with a scale or rule in order to determine the differences. Close measurements such as the .001 in. limit in piston rod diameter are impossible to measure with machinists' calipers. Another consideration is the greater ease in reading micrometers.

Axle and Crank Pin Calipering

Axles and crank pins can best be fitted by the use of micrometers. The wheel bores are not exactly to drawing

size owing to wear and other causes and the corresponding parts must be fitted accurately to insure safety. Each .001 in. difference in diameter between a car axle and steel wheel bore varies the mounting pressure from 5 to 10 tons. As an example, assume that similar steel wheels are bored exactly 7 in. One axle, turned to 7.007 in. diameter, will mount at about 70 tons pressure, and another axle, turned to 7.008 in. in diameter, will mount at 5 to 10 tons higher. Wheels and axles are fitted correctly in everyday practice when measured with machinists' calipers and nothing is to be said against the good work that is being done. This close measuring can be done more accurately and quickly, however, by the use of micrometers and the number of misfits will be reduced. The operation of calipering an axle fit in a wheel center is shown in Fig. 4.

In order that the axle and crank pin may be a secure fit in the wheel center, a uniform bearing from end to end is necessary. Likewise, the wheel center should be bored a uniform diameter its entire length. Unless the machinics are in an excellent state of repair and the work well done, there are possibilities of the parts being tapered, which is difficult to measure correctly with machinists' calipers. This bad practice may go on for some time if not detected with micrometers and remedied.

Side Rod Brasses

Boring side rod brasses to suitable sizes for running fits on worn crank pins in locomotive repair work is also adaptable

Fig. 4.—Calipering the Bore of a Wheel Center.

to the use of micrometers. It is necessary to measure each pin accurately and bore each brass a definite amount larger than the pin, subject to a reasonable machining tolerance. As an example, suppose good practice indicates that the bore of the brass for pins 5 in. to 6 in. diameter should be not less than .010 in. or more than .015 in. larger than the pin, in order not to cause heating by reason of too tight a fit, or too much lost motion on account of too loose a fit. If the crank pin is exactly 6 in. the brass would be bored between 6.010 in. and 6.015 in. The next crank pin may have more wear and only measure 5.970 in., in which event the brass would be bored between 5.980 in. and 5.985. All the refinements possible with solid limit gages may be obtained with micrometers and any set degree of tolerance quickly measured. For force fits of brasses in rods an allowance of .002 in. to .003 in. is usually made, and this can always be best measured by micrometers.

Crank pins can be measured more quickly with micrometers than with calipers and scale and the sizes set down on a memorandum or form. The operation of measuring new pins is shown in Fig. 5. When boring rod brasses, the inside micrometers can be set quickly and the bore measured with

sufficient refinement to insure its coming within required tolerances.

The use of micrometers makes it possible for a designated person to measure all crank pins and similar parts. Where this method is followed memorandums made of the measurements may be given to the various machine operators who will not be called on to leave their machines to go to distant parts of the shop for the purpose of measuring locomotive parts too bulky to take to the machines. This will result in less idle time of machines.

Crank pins are generally found to be worn out of round and tapered when the locomotive comes to shop for repairs.

Fig. 5.—Crank Pins Are Calipered and the Dimensions Filled in on a Form.

The amount out of round or taper should be ascertained in order to judge as to the necessity of re-finishing or renewal. By measuring the pins at the necessary points with micrometers the exact amount of wear will be at once detected. Where a limit has been set governing this wear the question of passing or repairing will be at once settled.

Cylinders

For the purpose of measuring the bore of cylinders, inside micrometers as shown in Fig. 6 are used. They have a range

Fig. 6.—Checking the Amount of Cylinder Wear.

of only one inch, which makes it necessary to provide one for each one-inch range in order to measure cylinders handled by any shop. Inside micrometers are also made with an extension piece, by which a considerable range of sizes may be measured with one instrument. This reduces the number of

calipers required, but also introduces chances for error on account of improper setting of the extension piece. The bore of cylinders when new should be measured to ascertain if they are reasonably close to drawing size, as it is a question whether locomotive cylinders can be bored commercially to exact micrometer sizes. However, they may without too great refinement be bored to a limit of 1/64 in. or .016 in. Measurements made with micrometers of the bore at each end will at once check this dimension, and should there be too much of an error steps may be taken to remedy the defects.

When locomotives are repaired the cylinders should be measured in order to determine the wear, or the amount the walls are worn hollow resulting from the travel of the piston head or other causes. On some roads a limit has been set governing this amount, that may be 1/8 in., 3/16 in., etc., depending on conditions. When measured with micrometers, the readings will at once show the amount of variation there may be between different parts of the cylinder and will indicate if reboring is necessary. When turning piston heads, the memorandum taken of the cylinder bores may be made use of by deducting the amount the piston head should be smaller than the cylinder bore.

The disadvantage in measuring cylinders with machinists' calipers is the possibility of error owing to their adjustment being changed while carrying, and also errors due to setting

Fig. 7.—Callpering a Valve Chamber Bushing.

one caliper to another. It would be difficult if not impossible to establish limits of variation from the required sizes for turning the piston head on account of the difficulty of reading machinists' calipers closely.

In measuring piston rods and valve rods a few points about the diameters should be considered. Both rods should be of uniform diameter where passing under the rod packing, and unless this is the case, rapid wear of the packing will result. These parts need not be machined to exact diameters, but they should be as close to one size from end to end as possible. By the use of micrometers the rods may be measured at various places and a limit of .004 in. or .005 in. maintained. Where rod diameters are checked with micrometers a decided improvement will be noticed in the reduction of steam leaks.

Piston Valves and Bushings

In order to obtain proper working piston valves it is necessary to make the valve of the correct size in reference to the bore of the bushing into which it works; also, the bushings must be of the right size in order to obtain the desired results. Most valve chambers will be found out of round in the bore for the bushings resulting from the heat of the steam and

natural distortion of the casting. By measuring the bore horizontally and 1/3 the way around from the horizontal with inside micrometers, and taking the average of these readings, the average diameter of the cylinder bore is obtained. This size plus the amount the bushing should be larger to allow for a force fit in the cylinder will be the diameter that the bushing should be turned.

Valve bushings are bored larger than the average diameter of the valve chamber bore an amount which will vary with the different diameters of bushings and thickness of walls and may be .005 in. or .007 in. When micrometers are used, experience will soon indicate the exact amount that this should be and bushings may be turned of correct size to insure a proper force fit in the cylinders, avoiding the possibility of steam leaks. When measuring the bore of new bushings or determining the exact amount of wear, inside micrometers may be used as shown in Fig. 7. The diameter of the piston valve bull rings may be measured by a method similar to that explained with reference to piston heads.

Driving Axles and Journals

The journals of driving axles are usually found to be worn out of round, tapered, or both. A slight variation from a perfectly round and uniform diameter does not necessarily call for refinishing; but there is a point between the slightly worn and the excessively irregular axle where refinishing becomes a necessity. This is in some shops governed by a set limit of 1/32 in. or, for easy figuring, .030 in. Measuring the journal with micrometers makes it easy to determine if the limits have been exceeded. As an illustration—if a journal measures 9.860 in. at one place and 9.880 in. at another, showing a difference of .020 in., refinishing would not be considered necessary. Should the readings be 9.870 in. and 9.910 in., making a difference of .040 in., the journal must be refinished.

In the case of a journal having a difference in diameter of only .020 in., a record may be made of the size and made use of when boring the driving box; likewise, the sizes of the journals may be measured after returning for the same purpose. Accurate measuring of the journals after refinishing is in many respects quite important on account of the possibility of their not being regular in size owing to the heavy counterweight on the wheels throwing the lathe out of balance. Improper setting of tool posts also often results in tapered journals. In actual practice micrometers will be found of the greatest value on this work by showing up bad workmanship and lathes not in the proper state of repair or setting.

Driving Boxes

The crown brass of a driving box is somewhat difficult to caliper on account of not being a full half circle, and as a result ordinary calipers cannot be used. In order to overcome this difficulty special three-pronged calipers, as explained in the *Railway Mechanical Engineer* of March, 1919, have been devised. These calipers are illustrated in Fig. 8. Without going into the description too minutely, it may be said that the three prongs, *H*, *H*₁ and *H*₂ are forced outwards by the descent of the taper plunger *G*, that in turn is controlled by the micrometer head *E*, the diameter being indicated by the readings on the micrometer dial similar to the method of reading any instrument of this nature. The various springs and appliances shown are for the purpose of taking up lost motion and making the caliper workable.

In practice, journal diameters are measured and sizes recorded on blanks or memorandums, as already explained. The amount the crown brass should be larger than the axle is added to these sizes and the box bored accordingly. During the boring and after its completion the exact bore of the brass is measured with the special calipers shown.

The advantages of this plan as compared with older methods are principally that the diameter of the axle and

driving box may be closely measured and the shell made a definite amount larger than the axle. Where this amount has been carefully worked out and checked, the work of scraping a box to fit the axle may be eliminated, which will result in quite a saving in labor. The three-prong calipers are also useful for checking the accuracy of the rams of boring mills used for boring boxes. These rams are liable to be set out of perpendicular with the mill table and bore larger at one end. A measurement made at both sides of the box will indicate whether the ram is properly set.

Car Wheels and Axles

Micrometers are now used quite extensively for the purpose of measuring the sizes of car axles after being turned. In order that the wheel shall be a safe and satisfactory force fit on the axle the wheel seats should be of a uniform diameter throughout, as in the case of driving wheels. With the more numerous repaired axles it is the general practice to re-turn them to the largest diameter to which they will true up, and as a result each wheel seat is of a different diameter. Measuring by micrometers will be found quicker and more accurate than any other method.

If the difference in diameter from end to end of the wheel seat for steel wheels is kept within .003 in. and for cast iron wheels .005 in., good results will be obtained. For the pur-

Fig. 8.—Three-Pronged Micrometers for Driving Boxes.

pose of checking these sizes the wheel seats should be measured at ends and in the middle, and the sizes recorded on a memorandum for use when boring the wheels. For steel wheels, the axle should be about .001 in. larger than the bore for each one inch of diameter. That is, for a 7-in. wheel bore, the axle should be about 7.007 in. in diameter. Cast iron wheels would require about double this amount. Inside micrometers are made use of for measuring the bore sizes in order to insure their being correct; also to ascertain if the bore is of one diameter from end to end. This operation will detect any taper and prove the correctness of the size in refer-

ence to the axle diameter. An error in turning or boring could not be accurately measured with machinists' calipers. Boring bars having micrometer dials are now largely used for wheel boring and, where wheel seats are measured with micrometers, the sizes for setting the dials on the bar will be at once indicated. As a result, the bar may be quickly and accurately set for as many different sizes as may be required in practice.

The uses for micrometer calipers that have been mentioned can only be considered as representative cases. Where

Fig. 9.—Adjustable Outside Micrometers Must Be Used With More Care Than Solid Instruments.

these are once introduced into a shop their use will spread to practically all machining operations where reasonably accurate measurements are required. On account of the ease with which measurements may be made and the accuracy readily obtainable the average workman will prefer these to machinists' calipers, and, when once introduced, there will be difficulty in getting the men to use other forms of measuring devices.

BLIND WORKERS IN CLEVELAND SHOPS.—Sixty-nine manufacturing operations, principally in the metal-working industries, are now performed successfully by blind workers in Cleveland, according to an article in the *Iron Age*. This city was among the first in the country to see the possibilities in industry for blind artisans, and a start was made in February, 1913, when the Society for the Blind placed one man with the Lake Erie Bolt & Nut Company. He did hand nutting and his pay ranged from 80 cents to \$1.25 a day. The movement progressed slowly until war-time conditions created a shortage of labor and since then many openings have been secured. Today there are 81 blind men and women working in 40 different factories. Some of the operations performed include assembling parts, nutting bolts by hand and machine, operating machine tools, packing and sorting. The electrical field has so far revealed more practicable operations than any other, but machine operations have been proved feasible for blind workmen.

THE MANUFACTURE OF SEAMLESS STEEL TUBING*

An Outline of the Method Used in Making Shelby Seamless Steel Tubing from Solid Blooms or Billets

SO many seamless steel tubes and flues are used in repairing and maintaining locomotive boilers and for various mechanical purposes that it is believed the following brief description of the modern methods of making seamless tubes will be of general inter-

Fig. 1.—Square Billet Entering Bar Mill

est to railway shop men. Satisfactory tubes cannot be made without uniform steel of good quality. This steel is delivered to the heating furnace in blooms of several sizes and weights, 6 to 10 in. square by 11 ft. long and weighing 1,300

Fig. 2.—Pneumatic Centering Machine in Operation

to 3,750 lb. After the blooms have been carefully inspected for surface defects, and any irregularities chipped off with pneumatic chisels, they are conveyed by a crane to a furnace

*Extracted from a booklet entitled "Shelby Seamless Steel Tubes and Their Making," by the National Tube Company, Pittsburgh, Pa.

room where an electrically operated charging mechanism picks them up one by one and places them in a heating furnace.

When the proper temperature for rolling has been reached, the bloom is pulled from the furnace by the long arm of a crane or transfer mechanism and placed upon a small electric buggy; this buggy transfers it to the rolling table of the bar mill (Fig. 1) where it passes through a series of rolls which changes the square bloom into a round bar of smaller size and greater length. Different sizes of round bars are thus rolled according to the size of tubes required to be made from them. Some of the bars are 8 in. in diameter when finished, while others are as small as 3 in. While still at rolling heat, the round bars are cut to different weights (according to the length and wall thickness of the finished tube) by a circular saw, and centered while still hot (Fig 2). They are then allowed to become cold, afterwards being inspected, marked with a die to identify the steel, and sent to the piercing mill.

The bars are now known as billets, or "rounds," and

Fig. 3.—Heated Billet Entering Piercing Mill

contain just enough metal for making tubes of the desired length, thickness and diameter, and to compensate for normal losses incident to the manufacture of the tube. After the billets have been centered, inspected and marked, they are placed in a heating furnace of special construction. The bottom of the furnace is inclined, and centered billets of the proper length are fed into the upper and cooler end, from which they roll by gravity to the lower end, where the temperature is high enough to render the steel soft and semi-plastic.

The piercing mill (Fig. 3) is located close to the discharging end of this furnace and the billets are fed into it, centered end foremost. The solid billet, almost white hot, is pushed forward until it is caught by the revolving rolls of the piercing machine which force it over the piercing point of a mandrel. As the billet is forced over this bullet-shaped point by the combined forwarding and rotating action of the heavy revolving rolls (Fig. 4) a dull, grinding sound

is audible. While enormous force is required to operate the piercing machines, there is nothing spectacular about the operation, nor much suggestion of the power required to displace the metal from the center of the hot billet toward the outside. So powerful are the revolving rolls of the piercing machine and so carefully planned is each part of the massive machinery, that the billet is transformed into a tube with apparent ease.

The newly pierced billet is simply a rather rough, thick-walled, seamless tube. It is raw in appearance and not particularly true to size and retains the knurl marks of the piercing rolls on its battered surface. There is positively no weld or seam, however, the round bar of steel having been

Fig. 4.—Diagram of Piercing Operation

pierced quite through its length, as a potter would force a pointed rod through a cylindrical mass of moist clay. Because of the thickness of its walls, the pierced billet is short and to change this thickness into length is the next requirement. Accordingly, it is rolled through adjustable rolls and over a mandrel held in the roll groove by a long

Fig. 5.—Diagram of Reeling Operation

steel bar, where the wall thickness and diameter are reduced. In this manner the pierced billet is converted into a longer tube with walls of uniform thickness having a fairly smooth finish.

While still at suitable working temperature, the rolled tube passes on through the reeling machine. This is another

form of rolling machine, consisting of two heavy rolls of special design (Fig. 5), set with axes askew, which may be adjusted to a thousandth of an inch. As the tubes are fed through these rolls any mill-scale is removed and they are given a smooth, burnished surface, the outside diameter of the tube being corrected to some extent.

From the reeling machine, the tubes pass to the sizing or

Fig. 6.—Reheated Tubes in Sizing Roll

finishing rolls (Fig. 6) which give the exact outside diameter required. From the finishing rolls, the tubes travel to an inclined cooling table (Fig. 7) up which they slowly roll, and after being sorted and inspected are dropped into racks, ready for removal by electric cranes. The electric cranes transfer the hot finished tubes to cutting-off machines where the rough

Fig. 7.—Inclined Cooling Table

ends are trimmed from the tubes and the tubes are cut to proper length. Any slight straightening necessary is then done, the tubes thoroughly inspected (if boiler tubes, a hydrostatic pressure test is also applied), then stenciled, put in stock or sent to the shipping room.

THE ENGINEERS' COMMITTEE of the Fuel Administration issued a report which contained figures showing the effect of lack of cars on the cost of mining coal. This information is being circulated in a diagram published by the National Coal Association and is reproduced in some of the leading coal trade journals.

MASTER BLACKSMITHS MEET AT DETROIT

The Subjects Most Thoroughly Discussed Were
Frame Repairing, Spring Making and Reclamation

OVER one hundred members of the International Railroad Master Blacksmiths' Association were in attendance at the twenty-sixth annual convention, which was held at the Hotel Statler, Detroit, Mich., August 17, 18 and 19. Following the customary opening exercises the president's address was delivered by John Carruthers (D. M. & N.).

President Carruthers' Address

In opening his address President Carruthers referred to the fact that at the last convention, Birmingham, Ala., was chosen by ballot as the place for this year's meeting and explained to the members that inability to secure suitable hotel accommodations made it necessary to seek another meeting place. Detroit was chosen because, next to Birmingham, it had received the largest number of votes.

Speaking of the importance of the work of the Association, President Carruthers said in part: "Never before in the history of railroading have we felt so much in need of the newest and most improved methods to obtain better service and the greatest possible production. Let us have the co-operation of all the members to the end that the largest measure of good may be brought out of our deliberation both for ourselves as individuals and the companies we represent. It is up to the supervisory forces to untangle the mesh in which the railroads have been returned to their owners.

FRAME MAKING AND REPAIRING

By F. F. HOEFFLE
Louisville & Nashville

Wrought iron for new frames has been displaced by steel and the steel frame has been developed to better design and efficiency. But the modern well-designed frame breaks and failures often take place at strong sections where least expected. Our problem is, therefore, the repairing of frames.

The Thermit weld has brought about wonderful results in keeping power in service, yet there are conditions brought about by the Thermit weld which have not been overcome, such as holding in abeyance expansion and contraction. Where numerous Thermit welds have been made on frames in roundhouses and the welds are very close together, one is

Welds of Frame Members Which Are Bound Together, thus Preventing Freedom of Expansion and Contraction

led to believe that these numerous welds were caused by not holding expansion and contraction in submission.

When a Thermit weld is made on a frame at a point where two or three members are bound together, the expansion and contraction cannot take place freely; hence the weld is liable

to cause a strained condition at another point. Such portions of frames are seen with a number of welds, no matter how carefully preparations were made to overcome this faulty condition. A weld which is capable of adjusting itself with no danger of causing a stress at another point has proven to be a good proposition.

When an engine is brought into the South Louisville shops of the Louisville & Nashville for a general overhauling and it is necessary for the boiler to be dismantled, if the frames are in bad condition they are turned over to the smithing department and at once the entire set of frames is placed in a soaking pit and heated thoroughly, then allowed to cool. They are then brought into the blacksmith shop, all Thermit welds removed and the frames put in first class condition.

This practice has given the results we looked for, and is evidence that the anvil is the proper place to repair a frame.

The oxy-acetylene process is used to great advantage for such work as cutting and the filling of surface defects; but where a frame is broken its use is not considered a good proposition.

By G. W. KELLEY
Central Railroad of New Jersey

The successful use of the electric, oxy-acetylene and Thermit process for welding depends largely on the operator, who must be an enthusiast and must be trained as an apprentice

Charcoal Was Used to Heat the Upper and Lower Frame Rails for Expansion in Making This Thermit Weld

before he can become an expert and successful operator.

The use of these different methods of welding has produced wonderful results. However, in their experimental period, failures were made by many who did not understand the nature of the various metals, or did not allow for the proper expansion to take care of the contraction. The sketch will illustrate how much expansion is sometimes necessary where it has required 115 lb. or more of Thermit to make an engine frame weld.

The cast steel cross brace was cut out at A to permit the wax collar and mould to be applied. This was also necessary to allow the top rail of the frame to expand. We used three charcoal containers to get expansion: one on the lower

frame rail at *B* and the other two at the opposite sides of the weld. While the mould was drying and preheating the expansion was also taking place. When the proper expansion was obtained, which was $\frac{9}{32}$ in., the weld was made. When the frame was cold the tram was perfect. The cross brace was then electric welded by the metallic electrode process. We prefer charcoal to an oil burner for obtaining expansion because with the oil burner the contraction in the frame takes place much faster than in the weld. When the weld is made we let the charcoal remain in the metal containers and all frame members contract together. No more attention is required until the frame is cold, as we arrange to make the weld at the last working hours of the day.

Discussion

The discussion of this subject was confined practically to the application of the various welding processes and a variety of methods which have been used successfully with each process were brought out. The discussion indicated that at least among those taking part in it the Thermit process is still most generally used in welding complete fractures of frame members. In some cases this process has been adopted to the exclusion of the others except for building up worn surfaces. It was evident, however, that both the gas and electric welding processes are being used for heavy frame

SPRING MAKING AND REPAIRS

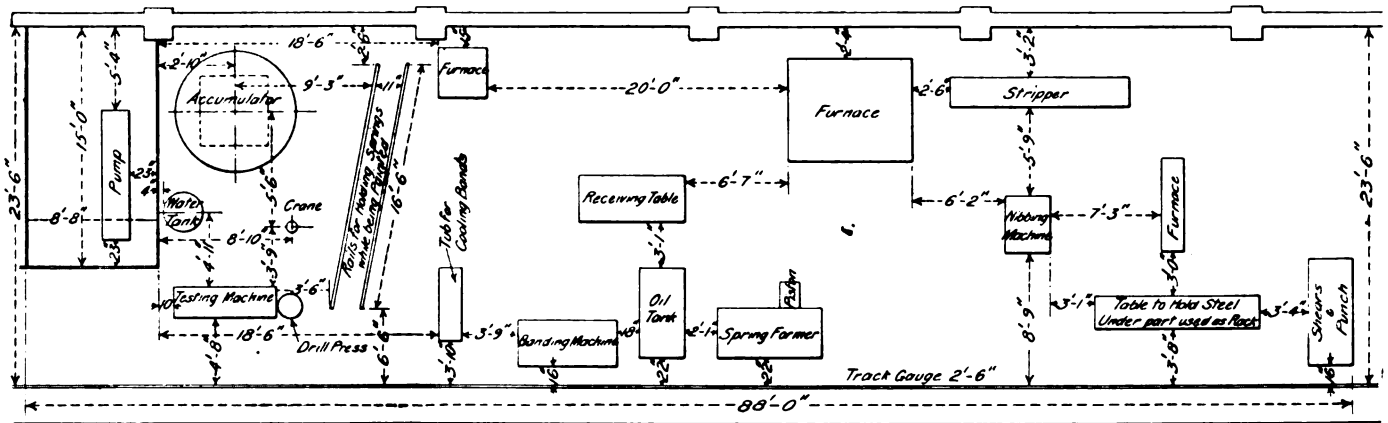

By J. W. RILEY
Lehigh Valley

In 1915 the management suggested that we submit a list of machinery that would be required for making and repairing of springs for the Lehigh Valley System. After going over the advantages of such a plant a decision was finally reached in favor of purchasing the machinery. The following is a list of machinery installed in the smith shop, occupying a floor space of 88 ft. by 22 ft. The arrangement, which is shown in the drawing, is very convenient.

Machines Installed in Lehigh Valley Spring Plant:

- Hydraulic steam pump.
- Hydraulic accumulator.
- Combination punch and shears.
- Combination nibber and trimmer.
- Hydraulic band stripper.
- Hydraulic bander with assembling table.
- Universal elliptic spring former.
- Oil tank with water jacket.
- Single fitting or forming furnace.
- Furnace for nibber and punch.
- Banding furnace.
- Thirty-five ton testing machine.
- Small air drill for drilling bands.

Before starting in the spring work I visited a number of spring plants and in most places found that they were equipped with rolls for forming. These were not much in

Layout of the Lehigh Valley Spring Shops

welding with complete success. The electric welding process is meeting with favor for this work because of the small amount of contraction which must be allowed for, thus simplifying the preparation for the welds. One of the members stated that with no allowance for contraction whatever where the electric process was used the effect of contraction would be no greater than with Thermit, oil or gas welds where the most careful preparation had been made. Excellent results have been obtained with the gas welding process employing the usual run of operators obtainable under the national agreement. Several members, however, dwelt on the necessity of more care in the training of operators if the electric and gas welding processes were to continue to advance. The practice of requiring welders to turn in test welds periodically, to be pulled in the test machine, is being followed by some master blacksmiths with excellent results. The welders are rated according to the strength of the welds relative to the strength of the unwelded material.

The national agreement, in making welding a preferred job in each craft, has tended to destroy permanency of employment on these jobs. The men consider the work temporary, often leaving it to return to the regular work of their trades before they have been at it long enough to become thoroughly skilled operators and the company suffers in consequence.

use, however, and the springs were being formed by tongs and hand hammers. This method is slow, is hard work for the spring maker and only an expert can do a good job. The tongs and hammer do not set the plates so they have a full surface bearing, strains are set up in spots, causing the leaves to warp when cooled in the oil, and it is necessary to over-heat heavy plates to be able to form them. Over-heating the steel is one of the greatest causes of broken springs. Another effect of over-heating is the reduction in the weight of the steel. A spring heated and formed about twenty-five times will be reduced about one leaf on a twenty-five leaf spring; the higher the temperature the greater is the reduction.

As a result I developed a universal elliptic spring former, which performed the work so successfully that the former was placed on the market and is now in use in several spring plants. With this the leaves are scientifically formed and any twist that may be in the steel is taken out. It is universal because it is ready at all times to receive leaves of any radius, length, width or thickness. With this machine the fitter requires no assistance from the heater, who may devote his entire time to heating and passing out the leaves. There is no need of heating the steel over 1,500 deg., F., as the machine will properly set the leaves at that temperature and it takes but an instant from the furnace to the oil. A master plate is used in setting the main plate and the balance of the

spring leaves are formed by pressing the hot leaf against the cold leaf. One stroke of the machine forms the leaf and gives it the desired amount of snap.

We do not taper the leaves. They are left square on the ends as they come from the shears. We use loose gib plates; some are cast steel, while others are formed in dies and made from scrap steel.

When we started repairing purchased springs we had eight men working 10 hours and a lot of overtime. After running a large percentage of the springs through the former the work kept decreasing until in a year's time we only required six men. Six months later only four men were working 10 hours and at present we have four men working 9 hours. These men do all the making and repairing for the Lehigh Valley System. The equipment consists of 1,000 locomotives, the tenders of which have elliptic truck springs, 700 coaches and 475 cabooses which have elliptic springs. These four men do not make bands. The bands are made in the forging machines and at the forge.

The records of one shop that had been using the tongs for fitting show an average of 36 trailer truck springs repaired

on a class of heavy trailer springs weighing 875 lb. each. The failures in these leaves occurred at the edges of the band. It was finally decided that the trouble was due to the broad bearing of the band against these leaves, which destroyed their flexibility and caused a concentration of load at the edges of the band. The trouble was overcome by rounding off the edges of the upper surface of the bottom side of the band, thus producing a crown bearing for the short leaves, which permitted them to deflect throughout their length.

RECLAIMING SCRAP MATERIAL

By F. B. NIELSEN
Oregon Short Line

In railroad shops of considerable size, in order to obtain best results in reclaiming scrap material, one of the first steps to be taken is the formation of a scrap committee. This committee should consist of representatives of the following departments: motive power, car, bridge and building, maintenance of way, and store department, accompanied by others qualified to pass judgment on the serviceable and scrap ma-

J. CARRUTHERS (D. M. & N.)

J. GRINE (N. Y. C.)
Second Vice-President

A. L. WOOLWORTH (B. & O.)
Secretary-Treasurer

per month. After the former was installed and a number of these springs run through the former the repairs to these trailer springs was reduced to six per month.

We use the flash temper. After using this method of tempering for four years I do not want to change to any other.

Discussion

The discussion centered around the practicability of making and repairing springs in railroad shops. The opinions expressed on this subject were generally in favor of this practice rather than purchasing manufactured springs and having them maintained either by the manufacturer or in the railroad shop. Where this practice has been adopted the results obtained have been substantially the same as those indicated by Mr. Riley in his paper.

The practice on most of the railroads whose representatives took part in the discussion is to repair springs on store department orders, replacement being made from store stock instead of directly from the blacksmith shop. The hammer test is generally depended on in large shops to detect broken leaves. This is applied either directly in the erecting shop or in a blacksmith shop. In some cases all springs are removed to the blacksmith shop, where those which pass the hammer test are placed under the spring testing machine to determine the load capacity before being passed as suitable for further service.

One case was mentioned where considerable trouble had been experienced from repeated failures of the short leaves

material. This committee should report to the superintendent of motive power at least once every week.

A committee of this kind has been established at the main shops of the Oregon Short Line at Pocatello, Idaho. It is composed of the superintendent of shops, engineer of the maintenance of way department, general foreman of the store department, general foreman of the car department and one or two foremen from the various departments who are invited to accompany the committee each week. This committee visits the scrap dock, taking out any serviceable material that may be used. Each case is taken up as an item on the minutes and given a number. A copy of the minutes of the meeting each week is sent to the head of each department and those responsible in each department are required to make a report to the chairman of the committee, as to why this material was scrapped.

A general inspection of the yards is made once each month, taking in all buildings, to see what material is lying around that is not being used. This is also reported.

This committee has proved very successful in reducing the amount of serviceable material found in the scrap pile and cases where such material is scrapped are constantly becoming more infrequent.

On the Oregon Short Line we have a re-rolling mill, and reclaim practically all small size iron, from 1/2-in. to 1 1/4-in. round, and from 3/8-in. by 1 1/2-in. to 3/4-in. by 2 1/4-in. All washers are made from scrap sheets and plates accumulated at the scrap dock. About seventy per cent of all scrap spikes

are reclaimed. These spikes are straightened in an air-operated machine constructed especially for this purpose. After being straightened they are put in a rattler to be polished. All second-hand bolts are reclaimed by cutting off and re-threading.

I have observed, from the different material removed from foreign line equipment that is coming into the welding room

Worn Picks Prepared for Reclamation by Welding on Stock Drawn Out from Scrap Mauls

of our shop, that proper attention is not given to oxy-acetylene welding.

Our practice is to give each welder a piece of steel 1½ in. square and 14 in. long all from the same bar. This piece is cut in the center, welded and then broken in a tensile testing machine. When we first began these tests the lowest record

efficiency. I feel sure that if this method were followed there would be no objection by the American Railroad Association to the reclamation of some of the material to which they now object.

Frogs and switch points are reclaimed and fair success has been attained in reclaiming manganese steel frogs and switch points. All track tools on the system are sent to Pocatello for repairs. When picks become too short we draw out some of the scrap spike mauls, which are then welded into the picks, making them of standard lengths. Claw bars are reclaimed by forging out the claw end from scrap tire steel and welding to the old bar. One of the illustrations shows the steam hammer dies employed in forming the claw ends.

Coil springs that are standard are reset and scrap springs are made into drift pins, small lining bars, jack bars, etc. The tamping and the spade ends of tamping bars are made from scrap coil springs. These are welded to the old bar. Scrap tire steel is drawn out for track lining bars, pinch bars, piston keys, spring hanger gibs, coal picks and similar pieces.

We have recently received a number of hollow heat treated locomotive axles. When obsolete they are reclaimed for making guides, counterbalance sheets, follower plates, dry pipe rings and dies for forging machines. We also reclaim piston heads with Tobin bronze. Main rods that are worn from lack of oil are also reclaimed with the same process.

Lathe tools for wheel lathes are drawn out of scrap tire steel and high speed steel is welded on by the oxy-acetylene process. Many shops do not seem to have good results in reclaiming these tools, and I do not think it is practical to make small tools by this process. Another important thing in the reclaiming of all material sometimes overlooked in the cutting and dressing of high speed tools, is that all pieces cut off and all broken small tools, such as drills, reamers, etc., should

Steam Hammer Dies for Forming Claw Bar Ends. Die No. 1 Draws the End and Forms the Heel; Die No. 2 Shapes the End; Die No. 3, with Flatter, Finishes the Heel and Curves the End; Die No. 4 Countersinks for the Claws; Punch Die No. 5 Forms the Claws

of tensile strength was 67 per cent of the original strength and the highest 83.8 per cent of the original strength, with a reduction of area of 8 per cent and practically no elongation. The last test made in April, 1920, by the same welders and the same method showed the lowest record of tensile strength to be 85.7 per cent and the highest 99.7 per cent of the original test, with an elongation of 6.5 per cent.

Through information obtained by this method the best welders are selected for reclaiming such material as couplers, frame work, and other work requiring a high percentage of

be saved and turned over to the store department for reclaiming.

By J. HARKIN
Southern Pacific

A reclaiming plant should be located conveniently to the segregating point of all scrap material and within easy access to the main shops and store. In order to operate a reclaiming plant economically it will be necessary first to determine the kind and the quantity of material of various kinds desired

to be reclaimed; when this has been decided upon there should then be installed the necessary machinery for reclaiming the various articles with the least possible expense.

At the Southern Pacific shops at Sacramento, Cal., brake shoe keys are being made from 3/4-in. or 7/8-in. scrap bolts or bars. Brake staffs for flat cars can be made from discarded brake staffs from box cars. We make split keys, angle iron for ladders on box cars, washer plates and door plates from scrap tubes. We use scrap coil springs for making the various styles of bars, packing hooks and packing irons used by the maintenance of way department and car inspectors; these bars vary in size from 3/8-in. round to 1 3/8-in. round and from one foot to five feet in length. All our claw bars, lining bars and tamping bar ends are made from scrap tires, as well as headers and dies used on our small size bolt and forging machines. We have been using scrap tire steel for making superheater unit bolts for locomotives with very good success; also we have for some time past been making the flat drills used by the maintenance of way department from scrap files. These drills are ordered in lots of 250 and vary in size from 3/4-in. to 1 1/8-in. and are usually 6 in. long. We have had very good service from these drills.

We reclaim all scrap 40-ton axles by working them over to 30-ton axles; while the 50-ton axles are reformed to a standard 40-ton axle. These axles are usually reclaimed in a

Die Blocks Used for Reclaiming Worn Draft Keys—Norfolk & Western

forging machine suitable for such work, but they are also reclaimed with tools made for the purpose under a steam hammer.

There are usually a number of articles such as handholds, brake rods, couplers, coupler yokes, bolts, nuts, track spikes, switch points, etc., that find their way to the scrap dock from various points on the line. Such material is inspected and much of it reclaimed, or, as some would prefer to say, repaired, and turned over to the store department and carried in stock.

While we give the closest attention to the reclaiming of material at our scrap dock, such as is mentioned above, our greatest success in reclaiming scrap has been accomplished in the rolling mills, where we are using over 5,000,000 lb. per month by rolling it into standard sizes of bar iron from 3/8-in. round to 3 1/2-in. round, and flat bars from 1/8-in. by 1/2 in. to 1 in. by 12 in. We also manufacture tie plates and angle bars, using material taken from the scrap pile.

By P. T. LAVENDER
Norfolk & Western

The drawing shows a set of hammer dies which have been developed for reclaiming worn draft keys. These dies are very simple to make and can be used in any steam hammer.

We first put the bent and worn draft keys in a furnace and when properly heated straighten them under a hammer. They are then placed in the die shown at the left of the die blocks, which spreads them 1/4-in. above size. Then they are placed in the die at the right, which brings them to the size required.

When the operation is completed the key is just as service-

able as one made from new bar stock. We work keys over two and three times before they are sent to the scrap pile.

By T. F. BUCKLEY
Delaware, Lackawanna & Western

Reclamation of scrap materials on railroads has been going on for many years, but lately, due to the high cost as well as the shortage of new material, more attention has been paid to this subject than ever before. Yet it must be recognized that wages have advanced and consequently too much time may be put on many articles, making them more expensive to reclaim than to provide wholly new parts.

Of course scrap is found everywhere from one end to the other of the road and reclamation should take place at a central point, preferably at the company's most important shops where facilities for handling it may be provided. Competent inspectors who thoroughly understand railroad material and its uses should supervise the sorting and reclamation.

Material to be reclaimed should be taken to the main shops, where the necessary steam hammers, shears, and such other facilities as the process requires are located.

Draw-head castings, steel couplers, bolsters and other parts of locomotives and cars slightly cracked but otherwise in good condition should be sent to the shops and have the electric or acetylene torch applied to them. Reclamation by welding has saved thousands of dollars within the past few years.

It may prove economical to provide an auxiliary preparation plant near the scrap dock, where materials can be partially prepared as they are sorted, thus minimizing the cost of handling. This plant should be equipped with bolt threading machines for re-threading bolts, rods, etc., with a nut tapper for retapping old nuts; with punch and shears for making washers and keys. A reclaiming roll for rolling up to 2-in. round and 1-in. by 4-in. flat can profitably be used; there should also be a steam hammer for cutting, straightening and hammering the heavier materials such as scrap axles; for reforming and hammered into round bars 3-in. to 5-in. rounds and making hammered iron into usable sizes, there should be furnace equipments in connection with the hammers and rolls. A plant of this kind can be made to pay for itself in a very short time under favorable circumstances.

In addition to being well versed in the quality of railroad material those in charge of the work should know whether or not it would pay to reclaim in special cases as they arise. Many articles may be reclaimed economically today, but not a month from now. So it is true that as reclamation is a good thing the returns gained thereby are large or small according to the intelligence used in carrying it on.

Discussion

The discussion developed the fact that others are following the practice of reclaiming worn piston heads by building up with Tobin bronze, which Mr. Nielsen mentioned in his paper. It is considered practical to reclaim pistons in this way with a maximum wear up to 1/4-in. thick at the heaviest part and extending around approximately one-half the circumference of the piston. This practice has also been used in reclaiming worn slide valves, and in both cases experience has indicated that the reclaimed parts remain in service without further repairs much longer than do new parts.

In answer to a question as to the advisability of manufacturing superheater unit bolts, Mr. Harkin stated that these bolts would not be made in the shop if they could be purchased, but that the use of tire steel, annealed after the bolts had been forged, has been successful. In using tires for the manufacture of parts requiring strength the practice of turning off the flange, and if the tires include inside retaining flanges, cutting these off with the acetylene torch was advocated. An attempt to forge the tire with the flanges left on usually results in the flange turning over and forming a seam in the material.

The greater part of the discussion was devoted to the reclamation of axles. Two general methods are being followed, one in which the whole axle is reworked, the body being drawn out and the journals upset, to reduce the reclaimed axle to the next capacity below that of its original state; and the other reworking the end of the axle only to restore them to the original capacity. The second method requires the addition of material to the ends of the axle. This is being taken care of at the Beech Grove shops of the Big Four by turning off the collar at the ends of the journal, heating the axle and upsetting the journal by forcing a wide angle cone punch into the ends of the axle and then jump welding a plug provided with stock for the collar into the cavity. Some of the members considered this practice open to objection because each time the ends of the axle are upset the distance between the fillets at the wheel seat ends of the journals on the opposite ends of the axle is reduced from $\frac{1}{4}$ -in. to $\frac{1}{2}$ -in.

The details of the first method as applied on the Santa Fe were described by George Fraser. The bodies of the axles are first swedged down to increase the length, one half of the axle being heated at a time. The journal collars are then broken down, the ends heated a few inches beyond the wheel seat and upset in a forging machine. The axle is not gripped in the dies but is held against an independent back stop which determines the length. The finished forging has one-half inch of stock for finishing to the required size for the next capacity lower than the original and the size of the body is larger than required by the M. C. B. rules. These axles provide an opportunity for using up wheels with oversize bore.

A question was raised as to the advisability of reclaiming scrap axles because of the uncertainty as to the condition of the material after the axle had been in service long enough to be worn beyond the limit for the original capacity. Some of the members considered the practice inadvisable, unless the material in the axle were reworked throughout its entire length.

Association Business

A Committee on Amalgamation with the American Railroad Association, Section III—Mechanical, appointed subsequent to last year's convention, presented a brief report outlining the probable status of the association should it amalgamate with Section III—Mechanical. The association authorized the committee to conduct the necessary negotiations with a view to accepting the invitation of Section III—Mechanical—of the American Railroad Association to become a member of the American Railroad Association—Section III—Mechanical—subject to a vote of approval at the next convention.

The secretary-treasurer reported a total membership of 245 at the close of the year and 21 new members were received during the convention. The balance in the treasury showed an increase of \$141.58 last year to \$227.82 this year. In order to continue to meet the increased cost of conducting the affairs of the association, however, the dues for the coming year were increased from \$4.00 to \$5.00 a year.

The following officers were elected to serve for the coming year: president, Joseph Grine, (New York Central); first vice-president, George Hutton, (New York Central); and second vice-president, S. Lewis, (Canadian National). W. J. Mayer (Michigan Central), who was first vice-president during the past year, was elected to the presidency; but owing to the demands that he be made secretary-treasurer to succeed A. L. Woodworth, who asked to be retired following a continuous service in this office of 22 years, Mr. Mayer resigned the presidency to accept the office of secretary-treasurer.

Montreal, Quebec, was unanimously chosen as the place for the next convention, with the provision, however, that the executive committee be empowered to make other arrangements should the best interest of the Association so require.

ADJUSTABLE CENTER BLOCKS FOR CRANK SHAFTS

By J. K. BLAIR
Norfolk & Western, Roanoke, Va.

In turning crank shaft bearings, it is usually necessary to make center blocks to accommodate every different diameter of end bearing and crank throw. As this is laborious and costly, the device illustrated herewith will be found a useful adjunct in the machine shop. It has been found very handy for turning the wrist bearing on various styles of stoker cranks and similar work. The block which carries the

A Useful Device for Stoker Repairs

adjustable center is bored large enough to accommodate the end bearing on the crank shaft, the end being split and a set screw placed in the side to hold the parts securely. In clamping smaller sizes, the hole is bushed. The sliding center works in a dove-tailed groove fitted with an adjustable gib and is moved back and forth by the screw as shown. A scale on the block indicates the offset between the centers of the bearings.

British Link Truing Device

Safety Locomotive Boiler Washout Plug

A WASHOUT PLUG of new design has been placed on the market by the Housley Flue Connection Corporation, Indianapolis, Ind. This plug has been in use for some time and has been thoroughly tested under

Housley Safety Washout Plug

service conditions. For test purposes a pressure of 1,800 lb. cold water has been applied and it is reported that the

plug withstood the pressure without leaking. The plugs used in the test were not especially designed, but were taken from the stock room.

The construction of the plug is indicated in the cross-sectional view illustrated. The sleeve 1, which is installed in the boiler sheet, is rolled in on a three-degree taper and remains permanently in place, special rolls and expanders being provided for this purpose. A particular feature of the plug is the protecting wall 2, which safeguards the threads against smashing or distortion caused by washing rods and hose nozzle. It also prevents wafer from touching the threads, allowing no scale, rust or sediment of any kind to form. The top of the protecting wall is the seating face for the gasket 3. This gasket fits snugly in the top of the plug cap in a special groove and does not drop out when the cap is removed. It is this gasket that solves the problem of leaky plugs, because when the plug cap is screwed down tight on a soft copper gasket leaks are practically impossible.

The plug cap 4 is the only part that is removed for a washout and in replacing, the caps cannot be cross-threaded because the protecting wall acts as a pilot. The nipple 5 or the lower part of the sleeve which fits in the boiler is rolled in the sheet on a three-degree taper, the larger end of the hole being in the boiler; 6 is the boiler sheet. Owing to the absence of scale and rust and the good condition of the threads, it is stated that one man can readily remove these plugs from boilers.

The Germ Process of Compounding Oils

PAPERS on the Theory and Practice of Lubrication by Henry M. Wells and James E. Southcombe, of the Henry Wells Oil Company, London, Eng., were read in Pittsburgh recently. The authors explain the rationale of the superior lubricating properties of fatty oils and of oils compounded with fatty oils over "straight" mineral oils (i. e. mineral oils not compounded). The property has hitherto been mentioned by various observers but left in that position. This led to an examination of the principles on which lubrication depends. It was demonstrated that liquids which wet solid surfaces are lubricants, while liquids which do not wet them are not lubricants; that one property which differentiates them is largely that of capillarity, or interfacial tension; that the fatty acids in fatty oils perform the functions of lubrication and not the fatty oil per se. It was also found that if the fatty acid be extracted from a fatty oil it is little if any better than a mineral oil as a lubricant

and that if a fatty acid in small quantities be added to mineral oils, their lubricating properties are very appreciably enhanced. Results in the laboratory were confirmed by several independent authorities.

On the practical side, the authors cite many examples where fatty oils, or oils compounded with fatty oils, have been entirely and successfully replaced in actual practice by Germ Process oils for lubrication of steam engines, gas and oil engines and many types of mechanism. Results of trials of marine engine oil on a large scale over 18 months, by the British Admiralty were cited. Germ Process oils are cheaper than fatty compounded oils, and are suitable for the heaviest work in all climates.

The title "Germ Process" selected by the authors is purely arbitrary—chiefly from the fact that hitherto engineers and chemists have had an aversion for the word "acid" connected with any oil. The authors not only dissipated that

fear by proving it was grounded on a complete misapprehension of its functions, but proved that the feared fatty acid was a very useful ally when its functions are understood and controlled, which, it is stated, the Germ Process

ensures. The claim is made that by this method of preparation superior oils can be obtained at a fraction over the cost of mineral oils. The Germ Process is the subject of patents in America, in the United Kingdom and in Europe.

Portable Pneumatic Punch and Riveter

THE illustration shows a new combination punch and riveter designed and built by the Baird Pneumatic Tool Company, Kansas City, Mo. It is adapted to the punching of light structural shapes in shops where the range of work is of small dimensions. By taking out the punch and die and inserting rivet dies of the proper size, the machine may be operated as a riveter and can be used effectively on the fabrication of light frame work. The air cylinder is so cushioned as to prevent injury to the mechanism when used as a punch.

The tool is operated by a fourway valve, by foot pedal and hand movement, depending on whether it is used as a stationary or portable unit.

The machine is made with both 1-in. and 2-in. die travel and has a punching capacity of 1/8-in. to 5/8-in. holes in cold 3/8-in. plate, and has a riveting capacity of 3/8-in. cold or 5/8-in. hot rivets.

The tool delivers 35 tons pressure on the rivet punching dies and weighs 500 lb. complete. This punch and riveter can be used to good advantage on the quantity production of small shapes. It is portable, takes up but little floor space,

and is stated to be economical in air consumption which is an important factor in machines of this character.

Baird Air Operated Punch and Riveter

Automatic Wrench of Simple, Compact Design

A SIMPLE, compact wrench, which is virtually automatic in action without the agency of a ratchet, has been developed recently. It was first used as a track wrench, but is equally applicable to smaller sizes of nuts. As illustrated, there are only four pieces to the wrench, the handle, interior jaw, exterior jaw and hinge pin. The interior jaw has a socket that fits over a knuckle on the end of the handle, while the exterior jaw encloses the interior jaw and is pivoted on a pin located a short distance behind

reaction, the two jaws move towards each other. The pin hole in the handle is slotted a sufficient amount to avoid any binding with the varying angular positions of the handle.

In using this wrench it is put on the nut in a position such that the direction in which the bolt is to be turned is

Diagrammatic Sketch Showing Wrench Operation

the center of the socket about which the interior jaw revolves. The engaging faces of the two jaws have corresponding grooves so that the two jaws slide in a fixed relation to each other as they rotate about their respective centers on the handle.

The operation of the wrench is best understood by reference to the diagrammatic sketch. In this sketch the handle is represented by *H*, the interior jaw by *A*, the exterior jaw by *B*, while the engaging grooves of the two jaws are simulated by the plunger and cylinder arrangement at *C*. It is clear that when the handle is turned in a clockwise direction, the two jaws move away from each other and that when the handle is turned in the opposite or counter-clockwise di-

Allen-Diffenbaugh Automatic Wrench

the same as the direction in which the handle must be pulled in order to bring the jaws together. The wrench is held by the operator so that the nut is always in contact with the interior (upper) jaw. When the handle is turned back, the exterior jaw will clear the nut. The action is automatic, the jaws separate as the handle is pulled back to take a new grip and come together again the instant that the handle is pulled forward to turn the nut. The wrench is manufactured by the Allan-Diffenbaugh Wrench & Tool Company.

High Capacity Single Purpose Drill

DESIGNED to meet the demand for a single purpose drill of simple and rugged construction, a machine has been placed on the market recently by the Minster Machine Company, Minster, Ohio. It is well adapted for use on quantity production work. Referring to the illustra-

No. 12 Minster Junior Drill

tion, the power is transmitted to a large driving pulley running at 600 r.p.m., and then through accurately ground, high carbon steel shafting to the hardened, stub tooth transmission gears. The gears are all accurately ground.

This machine is equipped with three mechanical speed

changes which are obtained through a sliding gear in the gear box, the teeth of which are rounded so as to enable the operator to change gears readily. The drive then passes through the hardened mitre gears to the vertical driving shaft, at the upper end of which are located the speed change gears. These gears in turn mesh with the gears on the flanged spindle sleeve. The drill comes regularly equipped with two sets of speed change gears, giving six speed changes, but any desired speed can be obtained by changing the combination of gears both on the vertical drive shaft and spindle sleeve.

A vertical shaft at the front of the machine drives the feedbox mechanism. The feedbox shafts are all accurately ground and cut steel gears are used throughout. Two mechanical feed changes are provided in the feedbox, which are compounded by transposing gears located conveniently on the front of the machine. The machine comes regularly equipped with one set of transposing gears, giving four feed changes. Any desired feed may be obtained by changing the feed transposing gears. The feedbox mechanism transmits its motion to the worm shaft, which in turn engages the large worm wheel keyed to the pilot shaft. Upon this shaft, a wide faced, stub tooth pinion is cut which engages the feed rack on the spindle sleeve. An efficient automatic feed disengaging device is provided.

The spindle, which is made of high carbon forged steel, is driven by a sleeve upon which are mounted the driving gears. Two driving keys are mounted diametrically opposite in the spindle sleeve, which engage two keyways in the spindle. This method of driving divides the strain on the spindle and thereby eliminates any trouble which may be occasioned through the spindle binding. The two driving keys are held in position by screws.

The No. 12 Minster Junior drilling machine can be provided with a compound table in place of a plain table if desired, the compound table being of heavy construction and thoroughly gibbed to provide for extra heavy service. The bases of all machines are provided with slots for receiving adjustable motor bases. The motor is mounted directly upon this base and may be attached after the machine has been installed; since it will be necessary to drill but four holes in the base to mount the motor, the adjustable slides which are usually furnished with motors can be omitted. A 10-h.p. constant speed motor running at 1,100 to 1,300 r.p.m. is recommended.

Screw Driver Attachment for Air Motors

FOR use in pattern, cabinet, or any wood working shops where many screws have to be driven, the screw driver attachment illustrated has been developed as a time and labor saver by the Independent Pneumatic Tool Company, Chicago. It can be fitted to the spindle of an air motor or readily adapted to use with electric drills if desired.

It is stated that an experienced operator using one of these screw driver attachments can drive fifty screws per minute, with less effort and make a better finished job than by hand. The principle of operation is simple. Under normal conditions, the socket holding the screw driver is disengaged from the motor spindle so that the screw driver may be placed in the head of the screw while the motor is revolving. Pressure on the motor causes a shoulder on the part connected to the motor spindle to engage a recess in the

socket and the screw driver revolves with the motor spindle. Removal of the pressure causes the parts to disengage. The arrangement illustrated measures 15 in. over all and will drive No. 12 wood screws 1 3/4 in. long.

Thor Screw Driver Attachment

Direct Motor Drive for Surface Planer

THE application of the individual motor drive to railway shop machinery has been extended to wood-working machines, a recent example of which is the motor-driven surfacer or surface planer developed by the Oliver Machinery Company, Grand Rapids, Mich. This machine is driven without belts or driving pulleys by means of a motor coupled directly to the cutting cylinder and providing a speed of 3,600 r.p.m. In order to provide the proper number of cuts per minute three high speed knives are furnished in the cutting head.

The particular advantages of this form of drive are a considerable saving in floor space, increased efficiency due to the lack of belts, greater safety in machine operation and the fact that the machine can be placed anywhere in a shop, regardless of the position of line shafts.

The Oliver single-cylinder surfacer is made of cast iron sides and ribbed girts, carefully machined and bolted together. Ample material in the flanges reduces vibration to a minimum and provides substantial floor support. An improved type of forged crucible steel cylinder, carrying two knives and steel chip breakers is provided. Two pressure bars, one acting before and the other after the cylinder, hold the work to the table. The front bar or chip breaker yields to any quality of cut. Positive feed is provided by

means of 3½-in. forged steel feed rolls. The machine is designed to plane six inches thick and 20 in. wide, with a

Surface Planer Arranged for Direct Motor Drive

lineal rate of feed of 24 ft. per minute. A five-horsepower motor is recommended to drive the planer.

Spur and Spiral Gear Hobbing Machine

FOR cutting spur and spiral gears also splining shafts and cutting ratchets and sprockets, the machine illustrated has been placed on the market recently by the Cincinnati Gear Cutting Machine Company, Cincinnati, Ohio. The gear hobber is particularly adaptable to the quantity production of spur and spiral gears but can be

Cincinnati 16-In. Gear Hobbing Machine

readily set up for machining a single spur gear. In cutting spiral gears, however, its advantage is only manifest in quantity production, the requirements of the set-up being such as not to lend themselves quickly to cutting occasional gears. The hobber is supplied with standard parts and change gears but for the manufacture of spiral gears it is necessary to provide special change gears.

Strength and rigidity are secured by the generous dimensions of the bed and housing of the hobber. The metal is distributed to provide the greatest stiffness possible and this contributes to the accuracy of the machine. The work spindle is horizontal and is supported rigidly by two long bearings in the work saddle. Both bearings are bronze bushed and the front bearing is tapered for taking up wear. The work saddle is taper gibbed to long narrow guides in a manner to prevent any sagging when the clamping bolts are loosened. Elevating and lowering are accomplished by means of a crank handle, the movement being recorded by a graduated dial reading to .001 in. The load is supported on ball bearing thrust collars making the action smooth and even. The indexing mechanism consists of a double thread worm and a cast iron worm gear which are entirely enclosed and run in a bath of oil, suitable adjustment being provided to take up wear. The indexing is continuous and automatic.

The guide of the hob slide is exceptionally long with square ways taper gibbed to reduce binding action. The design and construction are such as to provide for the proper swiveling of the hob spindle. This can be adjusted to approximately fifty degrees either side of zero and is set by a vernier reading to five minutes. An automatic stop for the entire machine at any point is provided for use on either belt driven or motor driven equipment. There is also a trip to stop the feed mechanism only.

Changes in speeds and feeds are secured by means of removable change gears, a sufficient range being provided to meet all average conditions. Maximum production is insured by a cutting lubricant system and pump of ample capacity. Spur gears up to 17¼ in. in diameter with a 12 in. face and spiral steel gears with a diametral pitch of 3 can be cut. The maximum distance from the hob center to the spindle nose is 19½ in. The maximum diameter of the hob is 4½ in. Twenty-six changes of hob feed can be obtained and eight changes of speed. When a belted drive is provided as shown, the driving pulley is 15 in. in diameter with a 3¼ in. face to run at a speed of 400 r.p.m.

Plain Grinder With New Phantom Guards

PRACTICALLY all grinding machines made by the Modern Tool Company, Erie, Pa., are now equipped with new phantom guards as illustrated. The new guard, supplied with the machine and without extra cost, is a combination of expanded or perforated metal riveted to an angle iron frame, thus assuring both lightness and strength. Objections heretofore found with the old type of heavy, unwieldy, cast iron guard have been eliminated and the new type is light and easily handled. It affords practically complete visibility of all moving parts which the old type of guard concealed. All gears, pulleys, and belts are completely enclosed.

The Modern phantom guard is a space-saver and permits machines to be set closer together. It is built to follow the lines of the machine. The corners, being rounded instead of square, do not project into the passageway. Hinged portions and hand holes make lubrication and minor adjustments easy without the necessity of removing the guard. The heavy cast iron type guard is cumbersome, and hard to handle, experience proving that lubrication and adjustments were often neglected because of difficulty in this respect.

The feature of visibility will not only permit all moving

parts to be seen, and watched, but will act as a check against accumulation of dirt. The new guard is supplied as a unit and can be placed in position or removed without the use of a wrench or screw driver.

Modern Grinder With Phantom Guard

Separating Water From Compressed Air

ALL railway shop men are familiar with the trouble due to condensed water getting into pneumatic tools and air operated devices throughout the shop. A simple device for removing this water from the air mains

Stratton Air Separator

is shown in the illustration. It is known as the Stratton air separator, and is manufactured by the Griscom-Russell Company, New York.

The separator consists of a close grain, iron casting, designed to withstand a pressure of 160 lb. per sq. in. As air and the water come from the condenser they are compelled to follow a helical path which causes a swirling motion. The water, being heavier, is thrown by centrifugal force out of the path of the air and against the walls of the separator which it meets at an angle. There is no spatter or splash and the water follows the walls until its motion is checked in the receiving space at the bottom, from which it may be drained. The operation of the separator is purely mechanical and it is essential, for satisfactory results, that air entering the separator shall be at a sufficiently low temperature to insure all the water vapor being condensed. In order that the separation shall take place when the air is at its lowest temperature, it is desirable to install the separator as near as possible to the point at which the air is to be used. In other words, it is better to install a number of small separators on branch lines than to install one large separator on the main line from the compressor. In case of long air pipe lines out of doors where there is a possibility of freezing, the separator should be placed in the line at a point just before the pipe leaves the building.

The water level in the separator is indicated by a glass gauge as shown and for convenience in operation it is recommended that a trap be installed to automatically drain the separator of water. Separators having various arrangements of inlet and outlet can be supplied to meet different piping arrangements and with air inlets up to 8 in. in diameter.

At a recent congress of the French Federation of Railwaymen, the former secretary, M. Bidegaray, was re-elected by 34 votes against 19 cast for Lardeaux, the extremist, who took an active part in promoting the recent abortive strike, according to a note in the Railway Gazette, London. M. Bidegaray was considered too moderate for the revolutionaries, who at the last congress ousted him from his position and then declared a strike. Three of the extremists are now under arrest and a warrant has been issued for the arrest of the fourth, who has so far eluded the police.

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the Railway Age, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, east of the Mississippi river, \$3.00 a year; west of Mississippi river and Canada, \$4.00 a year; elsewhere \$5.00, or £1 5s. 0d. a year. Foreign subscriptions may be paid through our London office, 34 Victoria Street, S. W. 1., in £ s. d. Single copy, 30 cents.

WE GUARANTEE, that of this issue 10,500 copies were printed; that of these 10,500, 9,216 were mailed to regular paid subscribers, 14 were provided for counter and news company sales, 259 were mailed to advertisers, 32 were mailed to employees and correspondents, and 979 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 105,150, an average of 11,683 copies a month.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and of the Audit Bureau of Circulations (A. B. C.).

C. D. Young, general supervisor of stores of the Pennsylvania, has been appointed representative of the American Society for Testing Materials on Engineering Council, succeeding Albert Ladd Colby.

The Locomotive Superheater Company has received orders for 92 superheater equipments to be applied to seventy-five 4-6-0 locomotives and seventeen 2-10-0 locomotives to be built by 12 different locomotive builders in Belgium.

The Interstate Commerce Commission has ordered Class I railroads to file with it quarterly reports giving particulars of the number of employees of various classes in the service at specified times, of the service rendered by such classes of employees and of the compensation paid for that service.

A Materials Handling Section of the American Society of Mechanical Engineers was organized at a meeting in the Engineering Societies building, New York, August 13. Robert M. Gates, Lakewood Engineering Company, acted as temporary chairman. A nominating committee was appointed and ballots will be sent out for the election of officers just as soon as the committee makes its report.

The Russian Soviet government has sent Messrs. Krassin and Ivitsky to London to negotiate for the purchase of locomotives. Mr. Krassin is a representative of the Soviet government and Mr. Ivitsky is the engineer in charge of design. It is reported that Russia needs 5,000 locomotives, but these gentlemen will negotiate for the purchase of from 200 to 300. However, the Polish crisis has temporarily held up the negotiations.

The Joint Conference Committee of the national societies of civil, electrical, mechanical and mining engineers has issued an invitation to engineering and allied technical organizations to become charter members of the Federated American Engineering Societies, the organization conference of which was held in Washington, D. C., on June 3 and 4. The engineering societies are also asked to appoint delegates to the first meeting of the American Engineering Council, which will be held this fall.

The claim made by the railway car builders and repairers of Great Britain for an increase of 6 pence (12 cents) per hour on time rates with an equivalent increase on piece rates and of 3 pence (6 cents) per hour for apprentices has been refused by the Industrial Court. The employers con-

tended that the increases already granted were sufficient to meet the increased cost of living and added that the high charges in connection with the car building trade were already causing a serious fall in the demand.

A despatch from Dallas, Tex., published in the *Manufacturers Record* states that \$18,000,000 will be spent by the Santa Fe system for new equipment, to be delivered at the earliest possible moment. Orders have been placed with manufacturers for 50 locomotives of the most modern type for both passenger and freight service, 3,000 gondola cars, 2,500 refrigerator cars and 5,000 box cars. Fifteen hundred of the box cars will be built especially for the handling of automobiles and furniture. The \$18,000,000 also provides for the purchase of a large number of passenger, mail, baggage and express cars.

A sectional committee of the American Engineering Standards Committee, 29 West Thirty-ninth street, New York, held an organization meeting on June 11, to undertake the standardization of plain cylindrical gages for general engineering work, under the sponsorship of the American Society of Mechanical Engineers. The immediate occasion for undertaking the work was a request of the British Engineering Standards Association for co-operation on the subject. It is understood that this committee will recommend to the American Engineering Standards Committee that the scope of the work should be broadened so as to cover all plain limit gages for general engineering work.

Chicago and Pittsburgh Sections, American Welding Society

A Chicago section of the American Welding Society was organized at a meeting of the members of the welding trade in Chicago on August 3. Representatives were in attendance from many of the railroads and also from many of the larger local industries. M. B. Osburn, assistant superintendent of the Pullman Car Works, was elected chairman; O. T. Nelson, president of the General Boilers Company, was elected vice-chairman, and L. B. Mackenzie, president of the Welding Engineer, secretary and treasurer.

The organization of the Pittsburgh Section of the American Welding Society was completed at a meeting held in the Chamber of Commerce auditorium at Pittsburgh, Pa., on August 12. Officers of the section elected at the meeting

are: Chairman, J. D. Conway, secretary and treasurer Railway Supply Manufacturers' Association; first vice-chairman, Dr. R. H. Brownlee, Brownlee Consulting Laboratories; second vice-chairman, H. H. Maxfield, general superintendent motive power, central region Pennsylvania System; temporary secretary, F. W. Tupper, American Welding Society; treasurer, F. O. Gardner, Pittsburgh Testing Laboratory.

MEETINGS AND CONVENTIONS

American Steel Treaters' Society.—The American Steel Treaters' Society and the Steel Treating Research Society will hold a joint convention at the Commercial Museum, Philadelphia, Pa., on September 14 to 18, inclusive. A comprehensive program will be presented covering all phases of the heat treatment of steel, including pyrometry, electric, gas and oil fired furnaces, forging temperatures, quenching mediums, carbonizing and the treatment of various special alloy steels. Several papers of especial interest to railroad men will be presented, the subjects including the heat treatment of locomotive forgings. Over 80,000 sq. ft. of floor space in the Commercial Museum will be devoted to an exhibit of heat treating appliances and heat treated products. More than 125 companies will be represented.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III.—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- SECTION III.—EQUIPMENT PAINTING DIVISION.—V. R. Hawthorne, Chicago. Convention, September 14-16, New American House, Boston.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.—J. P. Murphy, N. Y. C., Collinwood, Ohio.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. B. Baker, Terminal Railroad, St. Louis, Mo.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, 1145 E. Marquette Road, Chicago. Convention September 1-3, Hotel Sherman, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN STEEL TREATERS' SOCIETY.—W. H. Eiseman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411, C. & N. W. Station, Chicago.
- CANADIAN RAILWAY CLUB.—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting, September 14, Paper on Car Records and Their Relation to Transportation and Accounting will be presented by J. A. Altimas, Canadian Pacific.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago. Next meeting September 8, at Hotel Morrison, Chicago. Paper on Reclamation of Car Materials will be read by J. L. McCann, B. & O.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koenke, secretary Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Next meeting September 10, Hotel Statler, Buffalo, N. Y. Paper on Upkeep of Freight Car Equipment will be read by J. W. Senger, N. Y. C.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—J. C. Keene, Decatur, Ill. Convention, September 14-16, Windsor Hotel, Montreal, Que.
- CINCINNATI RAILWAY CLUB.—H. Boutet, 101 Carew Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, Detroit, Mich.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 702 East 51st St., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn. Convention Sept. 7-10, 1920, Hotel Sherman, Chicago.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.
- NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting October 12.
- NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York. Next meeting, September 17. Discussion of the Association of Railway Executives' plans for increasing the efficiency of operation of the railways.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Next meeting, September 3. Problems of the short line railroads will be discussed by various speakers.
- RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Friday in month, except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.—J. B. Frauenthal, Union Station, St. Louis, Mo. Meetings second Friday in month, except June, July and August.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y. Convention September 14, Chicago.
- WESTERN RAILWAY CLUB.—Bruce V. Crandall, Chicago. Next meeting September 20. The building of a locomotive in the plant of the

PERSONAL MENTION

GENERAL

C. H. BILTY has been appointed mechanical engineer on the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee, Wis., having returned from service with the United States Railroad Administration.

W. J. BOHAN, assistant mechanical superintendent of the Northern Pacific, with headquarters at St. Paul, Minn., has been appointed assistant general mechanical superintendent with the same headquarters.

J. B. BROWN, master mechanic of the East Carolina division of the Seaboard Air Line, with headquarters at Andrews, S. C., has been transferred to succeed F. W. Knott as master mechanic of the Alabama division, with headquarters at Savannah, Ga.

R. M. CROSBY, general master mechanic of the Northern Pacific with headquarters at Tacoma, Wash., has been promoted to mechanical superintendent of the lines west of Paradise, Mont., with the same headquarters.

H. M. CURRY, mechanical superintendent of the Northern Pacific, with headquarters at St. Paul, Minn., has been appointed general mechanical superintendent with the same headquarters.

H. K. FOX, acting mechanical engineer of the Chicago, Milwaukee & St. Paul, has been appointed engineer of tests with headquarters at the Milwaukee shops, Milwaukee, Wis.

E. R. GORMAN, assistant superintendent of the Eastern division of the Chicago, St. Paul, Minneapolis & Omaha, with headquarters at Eau Claire, Wis., has been appointed acting superintendent of motive power and machinery, with headquarters at St. Paul, Minn. Mr. Gorman succeeds J. O. Enochson, who has been relieved on account of ill health.

W. T. HAWKINS has been appointed fuel agent of the Missouri Pacific, succeeding W. J. Roehl, who has been transferred.

GEORGE F. HESS, superintendent of machinery of the Kansas City Southern, has been appointed superintendent motive power of the Wabash, with headquarters at St. Louis, Mo., succeeding E. F. Needham, relieved of those duties at his own request because of ill health. Mr. Hess was born in Fort Wayne, Ind., and entered railway service as a messenger boy in the mechanical department of the Pennsylvania in 1886. After a short service as machinist apprentice in the Pennsylvania shops at Ft. Wayne he entered the employ of the Cleveland & Pittsburgh at Wellsville, Ohio, as a machinist. He was later employed by the Cleveland, Canton & Southern at Canton, Ohio; by the Atchison, Topka & Santa Fe at Raton, N. M., and by the Wabash at Ashley, Ind. In 1897 he was promoted to roundhouse foreman at Montpelier, Ohio, and shortly after was transferred to Delray, Mich. He entered the service of the Grand Trunk as general foreman at Detroit, Mich., in 1899, and was later transferred to Battle Creek, Mich. In March, 1901, he was appointed enginehouse foreman on the Chicago, Rock Island & Pacific at Pratt, Kan. He was later transferred to Caldwell, Kan., where he remained until promoted to general foreman at the Forty-seventh street (Chicago) shops. He entered the service of the Baltimore & Ohio in March, 1903, as a master mechanic, with headquarters at Lorain, Ohio, and served in the mechanical department of this road during the next eight years. In August, 1911, he was appointed

superintendent of machinery on the Kansas City Southern, with headquarters at Pittsburgh, Kan., which position he occupied at the time of his recent appointment.

E. W. HOPP, master mechanic of the Racine and Southwestern division of the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee, Wis., has been transferred to Aberdeen, S. D., as master mechanic of the Aberdeen division, succeeding G. Lamberg.

W. J. HUGHES has been appointed master mechanic of the Racine and Southwestern division of the Chicago, Milwaukee & St. Paul, with headquarters at Milwaukee, Wis., succeeding E. W. Hopp.

C. G. JUNEAU, recently appointed acting master car builder of the Chicago, Milwaukee & St. Paul, has now been appointed master car builder, with office at Milwaukee, Wis.

G. LAMBERG, division master mechanic of the Aberdeen division of the Chicago, Milwaukee & St. Paul, with headquarters at Aberdeen, S. D., has been promoted to superintendent of shops, with headquarters at Minneapolis, Minn.

LEWIS K. SILLCOX, whose appointment as general superintendent motive power of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, was announced in the August issue, was born in Germantown, Pa., on April 30, 1886, and was educated at Trinity School, New York, and the Mechanical and Electrical Institute of Brussels. He entered railway service in 1903 as an apprentice in the High Bridge shops of the New York Central, leaving there in 1906 to go with the McSherry Manufacturing Company at Middletown, Ohio. He resigned from that company as assistant shop superintendent in 1909 to become shop engineer of the Canadian Car & Foundry Company at Montreal. He left his position with the latter company in 1912 to become mechanical engineer of the Canadian Northern. In 1916 he was appointed to a similar position with the Illinois Central in charge of car work, from which he resigned on February 1, 1918, to accept an appointment as master car builder of the Chicago, Milwaukee & St. Paul.

On June 1, of this year the appointment of Mr. Sillcox as assistant general superintendent motive power of the Chicago, Milwaukee & St. Paul became effective.

SILAS ZWIGHT, assistant mechanical superintendent of the Northern Pacific, with headquarters at St. Paul, Minn., has been promoted to mechanical superintendent of the lines east of Paradise, Mont., with the same headquarters.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

G. F. EGBERS, master mechanic on the Northern Pacific with headquarters at Pasco, Wash., has been appointed master mechanic of the Idaho division, with headquarters at Parkwater, Wash.

H. MCLENDON, general locomotive foreman of the Seaboard Air Line at Savannah, Ga., has been promoted to master mechanic of the East Carolina division, with headquarters at Andrews, S. C., succeeding J. B. Brown.

JAMES SIMPSON, master mechanic on the Northern Pacific, with headquarters at Spokane, Wash., has been promoted to general master mechanic of the lines west of Paradise, Mont., with headquarters at Tacoma, Wash.

J. E. STONE has been appointed assistant master mechanic of the Southern Pacific, with headquarters at Sparks, Nev., succeeding Paul Jones, who has resigned.

C. A. WIRTH, road foreman of engines on the Northern Pacific, with headquarters at Pasco, Wash., has been appointed master mechanic, with the same headquarters, succeeding G. F. Egbers.

CHARLES F. PARSONS, whose appointment as general master mechanic, of District No. 1, of the New York Central at Albany, N. Y., was announced in last month's issue,

was born February 14, 1876, at Ilion, N. Y., and received his education in the grammar schools. In June, 1889, he entered the employ of the West Shore at Frankfort, N. Y., as messenger boy and was transferred to the store department in the fall of 1890. In the fall of 1892 he entered the locomotive department as a machinist apprentice. On the completion of his apprenticeship he resigned to accept a position as machinist with the New York, Ontario & Western, remaining with that company until November, 1896, when he returned to the West Shore as a locomotive fireman. In November, 1902, he was promoted to engineman and in April, 1910, to road foreman of engines on the Mohawk division. He became master mechanic of the Mohawk division on July 1, 1918.

Charles F. Parsons

JOHN F. LONG, district maintenance of equipment inspector of the Baltimore & Ohio, has been appointed master mechanic of the Connellsville division, Eastern district, with headquarters at Connellsville, Pa., succeeding H. J. Burkley, assigned to other duties. Captain Long served in France during the recent war in the capacity of inspector of equipment at Santes, France, master mechanic of the Paris & Mediterranean Railroad at Nimes Garde, France, and master mechanic at San Sulpice, and was commander of the 395th Casual Company, 35th Engineers. Previously he was employed on the St. Louis-San Francisco as machinist, assistant foreman, division foreman, general foreman, master mechanic and shop superintendent, and was for eight months with the United States Railroad Administration as assistant supervisor of equipment.

J. F. Long

SHOP AND ENGINEHOUSE

C. M. JACOBSON, shop superintendent of the Seaboard Air Line, with headquarters at Jacksonville, Fla., has been transferred to Portsmouth, P.Va., succeeding B. E. Greenwood, assigned to other duties.

F. W. KNOTT, master mechanic of the Alabama division of the Seaboard Air Line, with headquarters at Savannah, Ga., has been appointed shop superintendent at Jacksonville, Fla., to succeed C. M. Jacobson.

SUPPLY TRADE NOTES

Willaim S. Noble has been appointed manager of the railroad department of the Standard Paint Company, with offices in the Woolworth building, New York, and Plymouth building, Chicago.

George B. Malone, general manager of the K-G Welding & Cutting Company, New York, has also assumed the duties of district manager of the Philadelphia territory and has his office at 929 Chestnut street, Philadelphia, Pa.

Julius Janes, formerly president of the Standard Steel Castings Company, Cleveland, Ohio, has recently become associated with the Farrell-Cheek Steel Foundry Company, Sandusky, Ohio, as sales representative in Cleveland and Cuyahoga county.

The Mono Corporation of America announces the removal of its main office from Buffalo, N. Y., to 25 West Broadway, New York city, where a complete line of the automatic gas analyzing instruments manufactured by this corporation will be displayed.

A. B. Way, until recently secretary and general manager of the Bridgeport Chain Company, has become affiliated with the Chain Products Company, Cleveland, Ohio, in the capacity of district sales manager for New England, with headquarters at New York.

The Rogatchoff Company, 205 Water street, Baltimore, Md., has recently been incorporated under the laws of Maryland, with a capital of \$50,000, to manufacture adjustable crossheads for locomotives. A E. Davis is president, Theodore Rogatchoff is vice-president and H. V. Baker, secretary and treasurer.

William N. Thornburgh, Inc., and the Drexel Sash & Door Company, Chicago, have been consolidated and are now known as the W. N. Thornburgh Manufacturing Company, manufacturers of Thornburgh dust guards. The new plant and offices are located at Fiftieth avenue and Thirty-second street, Cicero, Ill.

New offices have been opened by the American Rolling Mill Company, Middletown, Ohio, in the Hibernia Bank building, New Orleans, La., to cover the southern states, including Texas, excepting El Paso. The office will be in charge of C. C. Lynd, who has represented the American Rolling Mill Company at Atlanta, Ga., for several years past.

The Oxweld Acetylene Company, New York, has established Pacific Coast sales and distributing headquarters at San Francisco, with offices at 1077 Mission street. Additional sales representatives' offices are maintained at the following points: Los Angeles, Salt Lake City, Portland, Seattle. Leo Romney is Pacific sales manager, with headquarters at San Francisco.

The Mesta Machine Company, Pittsburgh, Pa., has opened an office in the Singer building, New York, from which point all its foreign business will be handled. The New York office will also be the sales office for the New York and Eastern states territory. M. M. Moore, the export sales manager, who has just returned from a several months' European trip, will be in charge.

Arthur Jackson, formerly of the Gould, Shapley & Muir Company, Brantford, Ont., has been appointed Potter & Johnston representative with the Yamatake Company of To-

kio, Japanese agents for the Potter & Johnston Machine Company, Pawtucket, R. I. Mr. Jackson was at one time employed by the Jones & Lamson Company, Springfield, Vt., but for the past five years has been demonstrating and selling Gridley automatics in Great Britain.

A large interest in the Youngstown Steel Car Company, Youngstown, Ohio, has been acquired by the Youngstown Sheet & Tube Company, and the Brier Hill Steel Company, both of Youngstown. The plant represents an investment of about \$1,000,000 and will be used chiefly for repair work. It is intended later to erect additional works for the building of steel cars complete and plans have been outlined for a plant to cost at least \$5,000,000.

The Uehling Instrument Company, 71 Broadway, New York, manufacturer of fuel economy equipment, announces that it is now being represented in the New England states by the Smith Engineering & Supply Company, 89 State street, Boston, Mass., manufacturers' agents and engineers, specializing in power plant equipment. S. W. Smith, president of the latter company, was until very recently associated with the Uehling Instrument Company, with headquarters in its New York office.

M. E. Hamilton has become associated with the Automatic Straight Air Brake Company as field engineer. The company has started to build up its field organization to take

M. E. Hamilton

care of the brake installations which it will soon be making. Mr. Hamilton entered railroad service on the C. K. & N. Railway (construction company of the Chicago, Rock Island & Pacific) in the fall of 1887 as fireman. Early in 1890 he entered the service of the Atchison, Topeka & Santa Fe as a brakeman, and in 1891 was promoted to conductor at Galveston, Tex. From the fall of 1901 he worked for the Galveston, Houston & Henderson as engineer

and roundhouse fore-man until 1903, when he went back to the Santa Fe as engineer. In 1906 he was made air brake instructor; in 1909 he was made general air brake instructor of the system with headquarters at Topeka, where he remained until 1911, when he became railroad representative for the Garlock Packing Company. He re-entered railroad service as general air brake inspector for the St. Louis-San Francisco in 1915 and in 1919 resigned to enter government service as field inspector for the Bureau of Safety, Inetrstate Commerce Commission.

The Heald Machine Company, Worcester, Mass., announces two recent changes in organization. W. A. Erickson, who has been demonstrating and selling in the New York district, has been made district sales manager in Buffalo and will open a branch office at a location as yet undecided upon. S. M. Hershey has resigned as sales manager at Philadelphia and his position will now be held by A. Sleath, who has been representing the Heald Machine Company in the south.

The Bourne-Fuller Company, Cleveland, Ohio, and the Upton Nut Company, Cleveland, Ohio, have effected a consolidation under the name of the Bourne-Fuller Company,

Cleveland, Ohio. The ownership and management of these companies has been identical for the past eight years. The Upson Nut Company plants will continue operation as the Upson Works of the Bourne-Fuller Company, the product of its nut and bolt departments being marketed under the same trade-marks as in the past.

George E. Long, senior vice-president of the Joseph Dixon Crucible Company, Jersey City, N. J., following his re-election as a member of the board of directors at the annual meeting, announced his decision to retire from the office of vice-president after 43 years of active service with this company, having begun as stenographer and advanced to the offices of secretary, treasurer and vice-president, respectively. He has taken an active part in the introduction of graphite as a lubricant and of silica-graphite paint.

H. A. Noble, vice-president of the Pittsburgh Spring & Steel Company, Pittsburgh, Pa., has been elected president to succeed D. C. Noble, deceased. S. F. Krauth, secretary and assistant treasurer, has been elected vice-president and treasurer, with headquarters at Pittsburgh. J. N. Brownrigg, eastern sales agent at New York, has been elected vice-president and eastern representative at New York, and M. F. Ryan, western sales agent at Chicago, has been elected vice-president and western representative, with headquarters at Chicago.

The personnel of the railway department of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has been rearranged and promotions have been made as follows: W. R. Steinmetz, manager of the heavy traction section, with Franklin W. Carter in charge of both foreign and domestic negotiations; E. D. Lynch, manager of the light traction equipment section, with George Skipton in charge of negotiations; J. L. Crouse, manager of the new railway apparatus and supply section, and K. A. Simmon, manager of the safety car and foreign railway equipment section.

Robert M. Gates has been appointed managing engineer in charge of the Philadelphia, Pa., district of the Lakewood Engineering Company, Cleveland Ohio, with offices at 1034 Widener building, Philadelphia. Mr. Gates is a graduate of Purdue University. He has been active in organizing the Material Handling Section of the American Society of Mechanical Engineers, and is acting as chairman of that section during its period of organization. He has devoted the past 12 years to the design, application and engineering surveys of mechanical means of conserving labor in the construction, industrial and transportation fields.

The sales, purchasing, accounting and executive departments of the Reed-Prentice Company, Worcester, Mass., Becker Milling Machine Company, Hyde Park, Mass., and Whitcomb-Blaisdell Machine Tool Company, Worcester, Mass., were recently combined and the main offices are now permanently located at 53 Franklin street, Boston, Mass. The various agencies throughout the United States that formerly handled the products of these factories are now displaced by direct factory branches in the various machine tool centers of the United States, and the three companies now have combined sales branches in Boston, Worcester, New York, Detroit, Chicago, Cleveland, and Indianapolis. The locations of the various offices are as follows: Boston, 53 Franklin street, executive office; Worcester, Reed-Prentice Company, Cambridge street; Whitcomb-Blaisdell Machine Tool Company, 134 Gold street; Hyde Park, Boston, Becker Milling Machine Company; New York, fifth floor, Grand Central Palace; Chicago, 26-28 North Clinton street; Detroit, 408 Kerr building, corner Fort and Beaubien streets; Cleveland, 408 Frankfort avenue; Indianapolis, 940 Lemcke annex.

TRADE PUBLICATIONS

HARDENING ROOM EQUIPMENT AND SUPPLIES.—The Waisner Manufacturing Company, Rockford, Ill., has issued a 12-page booklet describing its line of lead hardening furnaces, lead furnace preheating attachments, coke furnaces, carbonizing pots and carbonizing material.

LOCOMOTIVES FOR LOGGING SERVICE.—Record No. 96, published by the Baldwin Locomotive Works, Philadelphia, Pa., describes the conditions which must be met by locomotives in logging service and recommends types that are best suited for the purpose. Numerous locomotives built for this kind of service are illustrated and general data are given for each.

VANADIUM STEEL.—The Vanadium Alloys Steel Company, Pittsburgh, Pa., has issued a small booklet covering Vasco vanadium steel, a general utility tool steel for all purposes, particularly adapted to resist shock and strain. This steel is made in six different types, each containing a different percentage of carbon. The classes of work for which each is especially suited are listed and directions are given for the heat treatment of each type.

GAGES.—A new gage catalogue has been issued by the Greenfield Tap & Die Corporation, Greenfield, Mass. In addition to being a catalogue it contains valuable screw cutting and gaging data, and describes the latest methods in precision measuring and inspection. Graphic tolerance charts to aid in establishing manufacturing limits, and complete gaging systems to assist manufacturers in promoting standardization of their products are also included in the catalogue.

SHOP MACHINERY AND TOOLS.—The Brown & Sharpe Manufacturing Company, Providence, R. I., has revised its catalogue of machinery and tools. The new catalogue, known as No. 137, contains 609 pages, 5¾ in. by 3½ in., and is illustrated. It covers the complete line of equipment manufactured by this company, including milling and grinding machines, automatic gear cutting and screw machines, cutters, machinists' and test tools, and contains a number of tables for the convenience of mechanics.

SUPERHEATERS.—Bulletin T-5, published by the Locomotive Superheater Company, New York, describes the advantages of superheated steam for stationary power plants and presents the engineering reasons for these advantages from a new angle. The argument is clear and concise and should be of interest to all power plant owners and operators in every industry or power plant service. Charts are included showing the effect of superheat on steam consumption, the superheat required to prevent condensation and the increase in thermal efficiency due to superheat.

SURPLUS WAR MATERIAL.—The Way to Increased Production is the title of a booklet issued by the du Pont Chemical Company, Wilmington, Del., giving some facts regarding the sale of surplus war material taken over from the war plants of the du Pont Company. Although the book is not complete as an inventory of the material on hand, it gives an idea of the great variety of supplies for sale, including a large range of articles in daily use, also flat and gondola cars, gasoline and electric storage battery locomotives, steam power equipment, hoists, etc. General machine shop tools of all kinds are on hand, and there is also special machinery built for manufacturing purposes peculiar to the powder business but which can in many instances be used in other industries with slight changes.

THE CONVENTION NUMBER

SEPTEMBER is growing in popularity as the season for conventions of the mechanical associations. During one week last month, three railroad organizations met simultaneously in Chicago, Boston and Montreal, and at the same time the Society for Steel Treating, which numbers many railroad men among its members, was in session in Philadelphia. Under these circumstances it is difficult for the mechanical department officer to decide which meeting to attend and no doubt many were unable to be present at conventions in which they were vitally interested. The activities of the associations are of such importance to the readers of the *Railway Mechanical Engineer* that the editors felt it advisable to publish the full reports as promptly as possible. For that reason this issue is devoted principally to the proceedings of five of the associations that met last month and on the following pages will be found editorials commenting briefly on the outstanding features of the conventions. The account of the meeting of the Chief Interchange Car Inspectors' and Car Foremen's Association could not be included in this number because of delay in getting out the stenographic report. A movement is now under way to arrange for holding several conventions in the same location during successive weeks next year. This will not only be convenient for the supply concerns, but will also do away with having several conventions meeting at the same time.

The question of amalgamation with the American Railroad Association as divisions of Section III-Mechanical has been before practically all of the so-called minor mechanical department organizations. Definite action has already been taken by the Master Painters' Association, now the Equipment Painting Division of Section III-Mechanical, and by the American Railway Tool Foremen's Association. The Air Brake As-

sociation and the Master Blacksmiths' Association have acted favorably on the proposal, subject to ratification of the final negotiations at next year's conventions. No definite action has been taken by the other organizations. There is a natural reluctance on the part of the minor organizations to lose their identity and there are good grounds for justification of this attitude. It must be remembered that these associations were not organized by the railroads. They owe their existence to the enterprise of leaders among the men in the fields represented and such railroad support as they have secured has been earned by a demonstration of the value to the railroads of such organizations. Under these circumstances the desire to retain their identity and a high degree of freedom of action must not be condemned. On the other hand it must be admitted that the value of their work to the railroads could be greatly increased if the energy of the various associations were to be directed so that less overlapping and better co-ordination would result. The principal value of the associations to the members themselves is educational; and while they serve this purpose very well, it undoubtedly could be equally well served, were they to become parts of an organization which would make their work of much greater value to the railroads. It must be said that the committee investigations of the independent associations are seldom authoritative as now conducted and there are many big problems that should be analyzed which the associations are not in a position to handle with their present organizations. Under the plan of organization proposed by the American Railroad Association the individual associations retain "home rule" and a large measure of their identity. For such sacrifices of sentiment as they make they receive in return the assistance of the secretary of Section III-Mechanical, an opportunity to do more effective work and the prospect of good work receiving a recognition which it is not now accorded. The invitations extended by Section III-Mechanical present opportunities which the minor organizations can ill afford to pass by.

THE TRAVELING ENGINEERS' CONVENTION

THE Traveling Engineers' Association may not be the most technical, but it is assuredly one of the most practical of the railway mechanical associations. Moreover, it has the reputation of being one of the hardest working bodies and the recent convention in Chicago was no exception to the rule.

* * *

First and foremost in recent meetings of this association comes the fuel problem, the question of obtaining the maximum use out of every pound of coal.

Fuel Economy in the Lime Light

At this convention the operation and maintenance of mechanical stokers was considered from the viewpoint of *efficiency* and *economy*. Stoker manufacturers know that the locomotive stoker must live down the reputation of being an excessive fuel consumer. Spark losses with stoker operation are high and every effort must be made to eliminate this and other waste incident to the use of mechanical stokers. The secret of efficient stoker operation lies in the education of firemen. The stoker is automatic only in a limited sense; it will not perform efficiently unless handled intelligently.

* * *

Locomotive boilers have never been designed with a view to promoting circulation, although this is always the first consideration in the design of efficient

The Thermic Syphon

water tube boilers for power plant practice. Limitations with respect to size and capacity have governed locomotive boiler construction and water circulation has developed in just about the same manner that "Topsy" grew up. The principal claim for economy and increased boiler capacity with the application of the thermic syphon lies in the fact that it creates a defined path for circulation in addition to increasing the evaporating surface of the firebox. Some excellent results are being obtained with this device as outlined in one of the most interesting papers presented at the convention.

* * *

Notwithstanding the fact that the effect of excessive back pressure on the operation of locomotives is well known, it has

The Back Pressure Gage

been given little attention in practical locomotive operation. The primary object of adjustments of draft appliances is, of course, to improve the steaming of the locomotive, and so long as steam enough can be generated to do the work little attention is paid to the effect of the adjustments on the steam economy of the engine proper. Back pressures as high as 20 lb. and 25 lb. are not infrequently attained in every day service and seldom are disclosed so long as the locomotive maintains schedules or handles its tonnage. It is true that there is a growing dissatisfaction with the status of our knowledge of the locomotive front end, but it has not yet reached the point where the railroads are willing to take the measures necessary to place front end design on a scientific instead of a rule-of-thumb basis. As a means of disclosing just how bad conditions are the use of the back pressure gage mentioned in the report of the committee on draft appliances of the Traveling Engineers' Association is worthy of general application. The device is nothing more than a pressure gage in the cab, connected by suitable branch pipes to the exhaust cavities of the cylinders. Ultimately the greatest return from the use of this device undoubtedly would be the sentiment its disclosures would create in favor of a scientific investigation of the whole problem of locomotive drafting. But it would also be of immediate value in comparing draft conditions on various locomotives of the same class; it would show why some locomotives are unable to maintain schedules well within the capacity of others of like design.

THE PROBLEMS OF THE GENERAL FOREMEN

ALMOST every craft and every department of the railroad shop has a separate association which considers and reports on its own specialized branch of the work; in fact, the field might seem to be covered so thoroughly that there is little left for the General Foremen's Association to discuss. Undoubtedly the activities of this association should be devoted, not to the details of shop practice, but rather to the broad question of management. At the last convention more than ever before this underlying idea was brought out.

* * *

Probably no single question has caused so much concern to those who are responsible for shop output as the problem of

Handling the Labor Problem

on the whole there has been a falling off in output per man during the past four years and even increased wages have had little effect in speeding up production. The reason is probably to be found in the feeling of unrest that has been almost universal during the last few years. Efforts to overcome the decrease in output have often been unsuccessful because the decreased production was a result of general conditions. Apparently the turning point has come and improvement should be apparent within a short time. The present wage scale is satisfactory to a great majority of the employees. Reductions in prices give promise of a decrease in the cost of living and with slack times in numerous industries, the employees will realize the benefit of the continuous employment which railroad service offers. Nevertheless the handling of men will continue to be a problem. The day of the boss, the driver, is gone. To get results under present conditions the foreman must be a leader, one who can appeal to the men through a study of the motives that spur them to action. Even with the unfavorable conditions existing during the past two years some shops have made remarkable records in maintaining their output. Under present conditions it should be easier to obtain the desired results.

* * *

That the General Foremen's Association is looking beyond the internal problems of the shop is shown by the discussion

The Operating Viewpoint

of engine failures and running repair costs. The ultimate object in conducting a railroad is to produce transportation at the lowest cost per ton mile and per passenger mile. The mechanical department officer can best help to insure economical operation if he keeps this constantly in mind. Too many records for low cost of classified repairs have been made by slipshod methods which have resulted in loss of service and heavy expenditures for running repairs. In view of the practical impossibility of keeping a record of running repair costs for individual engines as is done in back shop work, the cost of classified repairs should not be taken as the most important index of the efficiency of the mechanical department. Tests have shown that even slight defects in valve gears, valves and pistons will cause a considerable increase in the fuel consumption. Failure to make minor repairs promptly is often responsible for engine failures. The few dollars that may be saved in making classified repairs are lost many times over if the work is slighted and the expenditures for fuel and for wages of train crews are increased. Another angle of the maintenance problem that deserves attention is the matter of clean engines. It is natural for enginemen to take pride in such a wonderful piece of machinery as the modern locomotive, but if the whole engine is covered with filth it becomes repulsive and in that condition the engineman is almost certain not to give the machinery the minute and painstaking attention that is so essential for securing the best results.

THE PAINTERS' CONVENTION

OF the several conventions held during the month of September, the meeting of the Equipment Painting Division of Section III-Mechanical, at Boston, was in many respects the most interesting because it marked the fiftieth anniversary of the association that has been known for many years as the Master Car and Locomotive Painters' Association.

* * *

From the chemical standpoint the most important problems in regard to paint relate to the manufacture and use of substitute materials for the more expensive elements that for years have been regarded as essential to the manufacture of high grade protective and decorative coatings. Turpentine has become a very expensive ingredient in paint; and when it is realized that it is not a permanent element in the finished surface but rather a vehicle assisting in the mechanical application of the paint it seems logical that among the multitude of available petroleum products a distillate could be found which would serve the purpose. Opinion at the convention varied as to the efficacy of these substitutes, but it should be noted that the representative of at least one very important railroad declared in favor of a substitute for turpentine and stated that he was using this material on an extensive scale with entirely satisfactory results. The railroads are striving for economy in every direction and the painters should lead rather than follow in the procession. Those who object to the use of a substitute for turpentine should make sure of their ground before advising their railroads that a cheaper substitute cannot be successfully used.

Regarding Substitutes for Turpentine

elements that for years have been regarded as essential to the manufacture of high grade protective and decorative coatings. Turpentine has become a

Sentiment at the Painters' Convention was strongly in favor of using only the best materials. Any material which tends to lessen the durability of the painted surface is costly because it increases the labor that must be expended in the upkeep of the car and labor is a much more expensive item these days than paint. It would be extremely costly to use inferior materials that made it necessary to paint a car more frequently than if better materials had been applied or to use cheaper materials that allowed the steel surface to deteriorate when more expensive materials would have prevented the damage. These considerations in turn suggest the interesting question as to whether the quality of paint can be wholly determined by a chemical formula. There are many who contend that the preparation of paint is an art and that only the most skilled artisans are capable of mixing the ingredients in such proportion as to obtain a satisfactory paint. The technical staff of the Railroad Administration prepared specifications upon which all of the paint required for the standardized equipment was purchased. Some complaints were registered at the time, but the paint purchased was generally well regarded. It would be very interesting to know how this paint has stood the test of time.

Use Only the Best Materials

surface is costly because it increases the labor that must be expended in the upkeep of the car and labor is a much more expensive item these days than

* * *

The most practical and progressive action taken by the painters at this convention was in regard to the uniform stencilling of freight cars. This was unanimously endorsed and the action of the association was also in favor of placing upon the owning road the cost of painting special badges or trade marks. It was shown that the cost of this special decorative work was considerable and that uniform stencilling would result in a considerable saving to all roads if universally adopted. It appears that many railroads have already adopted the uniform stencilling.

Uniform Stencilling Endorsed

unanimously endorsed and the action of the association was also in favor of placing upon the owning road the cost of painting special badges or trade

THE TOOL FOREMEN'S CONVENTION

AT the tenth annual convention of the American Railway Tool Foremen's Association, held at the Hotel Sherman, Chicago, September 1 to 3 inclusive, definite affirmative action was taken on the question of amalgamation with the American Railroad Association, Section III—Mechanical. The tool foremen, therefore, became the second of the so-called minor mechanical department organizations to join the American Railroad Association. The convention was well attended and technical reports and papers of exceptional value were read, followed in many cases by animated discussions.

* * *

Several papers were presented on special tool room devices and it developed that there are few tool room foremen who do not have a number of special and effective devices for performing various operations in the shop. These devices should be made known to other foremen through the medium of the association and various technical journals. It was pointed out that the future of the tool room foreman lies not in his ability to turn out satisfactory small tools and machine tool cutters, but in the extent to which he studies the problems of the other departments of the shop with a view to developing special jigs and tools to reduce the time and labor required on machine and erecting floor operations.

Special Tool Room Devices

* * *

Members who took part in the discussion of the paper on "Issuing and Checking Tools in Locomotive and Car Shops" were practically unanimous in support of the system of issuing by check number. Checks given to the men on entering the service should be presented at the tool room for all tools except chisels and machine tools. Periodical inspections of cupboards will serve as a check on the operation of the system and at the same time bring to light many tools that are being hoarded by mechanics against possible use. This condition is especially evident when there is a shortage of any particular kind of tool. Irregularities and disobedience of shop rules regarding the handling of tools should not be allowed to pass unnoticed.

Method of Issuing Shop Tools

* * *

Especial interest was displayed in the report of the Committee on Standardization of Boiler and Staybolt Taps given in detail elsewhere in this issue. Seven standard taps were recommended, including a 36-in. staybolt tap, a special spindle tap for work behind frames, a 24-in. staybolt tap made in three lengths and a button-head radial staybolt tap. These first four taps are made with Whitworth threads, 12 per in., this thread being recommended because it has a greater tensile strength and maintains its original diameter longer than either the V-thread or the U. S. Standard. It was pointed out that staybolt cutting machines must be checked often to make sure they are cutting accurate staybolt threads of the correct diameter. Boiler head and washout plug taps were recommended with a 3/4-in. taper in 12 in. and 12 U.S. standard threads per in., the latter provision being made because these taps are often manufactured in railway shops and the U.S. standard thread is less difficult to make than the Whitworth. The committee maintained that the adoption of standard taps as recommended would eliminate many irregularities and simplify the manufacture of taps for this particular service. It was also felt that under present conditions satisfactory taps can be secured at a more reasonable price from any first class manufacturer than can be made locally in a railroad shop.

Standardization of Boiler Taps Recommended

standard taps were recommended, including a 36-in. staybolt tap, a special spindle tap for work behind frames, a 24-in. staybolt tap made in three

THE STEEL TREATERS' CONVENTION

THE truth of the old motto "In union there is strength" seems to be demonstrated once more by the amalgamation of the American Steel Treating Society and the Steel Treating Research Society to form one big organization of men interested in steel treating. The new organization, known as the American Society for Steel Treating, springs at once into prominence among the American technical societies; its remarkable growth and strength were convincingly shown at the second annual convention and exhibition held at Philadelphia, September 14 to 18. Many valuable papers, some of which are abstracted in this issue, were read and presented by title at the technical sessions. With an exhibition distributed over 80,000 sq. ft. of floor space, practically every phase of the heat treating industry was represented. The present membership of the society is estimated at 2,800, more than one-half of whom attended the convention.

* * *

Several papers were presented on the relative efficiency of fuels and special emphasis was laid on the high cost and growing scarcity of fuel oil. Discussion brought out the fact that the average fuel oil furnace without proper equipment for vaporizing the oil, mixing it with air, and a pyrometer to indicate temperatures, wastes at least 33 per cent of the heat of the oil. This statement was made by competent authorities and indicates the importance of proper fuel mixing and temperature control apparatus to increase the efficiency of furnace operation. Owing to the fuel oil situation, the possible necessity of changing over to gas or electric furnaces was pointed out, with resultant advantages in greater flexibility, better control of furnace atmosphere and more uniform temperature of heated area.

Relative Efficiency of Fuels

Several papers were presented on the relative efficiency of fuels and special emphasis was laid on the high cost and growing scarcity of fuel oil. Discussion brought out the fact that the average fuel oil furnace without proper equipment for vaporizing the oil, mixing it with air, and a pyrometer to

* * *

A question of particular interest to railroad men in view of the attempted use of heat treated steel for locomotive motion work was brought out in the discussion of heat treatment and fatigue strength of steel. The conclusions were that there is only one quenching and one drawing temperature for maximum fatigue strength. Decarbonization has a detrimental effect on fatigue strength and parts should be heated in a non-oxidizing atmosphere. Duplication of regular heat treatment will hasten failure of such parts as have already been subjected to repeated stresses. It was pointed out that these conclusions hold for carbon steel and not necessarily for all alloy steels.

Conclusions Regarding Fatigue Strength

was brought out in the discussion of heat treatment and fatigue strength of steel. The conclusions were that there is only one quenching and one drawing temperature for maximum fatigue

* * *

The discovery of high speed steel by two American metallurgists, Taylor and White, revolutionized the steel treating industry and made possible production records never before thought of. The best results with any kind of tool steel, however, can be secured only by proper heat treatment. Several papers were presented on the heat treatment of high speed steel and showing the results of actual tests. The imperative need for better shop equipment for heat treating steel was pointed out. Altogether aside from the question of fuel economy, high speed steel is too expensive to be spoiled or heat treated in such a way as to secure any but the best results. Antiquated equipment together with guess-work methods of judging temperatures and treating the steel must be done away with because they result in inefficient or spoiled work, the cost of which may often equal the entire cost of the right kind of equipment. Money can be saved in many shops by the installation of modern forging, annealing, carburizing and heat treating furnaces; also the temperature control apparatus, pyrometers and other equipment necessary for their efficient operation.

Heat Treating High Speed Steel

records never before thought of. The best results with any kind of tool steel, however, can be secured only by proper heat treatment. Several papers were

COMMUNICATIONS

PIECEWORK AND PRODUCTION

ROSELLE PARK, N. J.

TO THE EDITOR:

The article in the July issue of the *Railway Mechanical Engineer* entitled "Piecework Needed to Increase Production" has been sharply criticised by the railway shop crafts on the ground that it misrepresented the American workman and advocated obsolete methods to increase production. The writer had no such intention, well knowing that when compared with the workers of other countries, the American workman excels in many ways, as was forcefully proved during the recent war.

Regarding the piecework system, the underlying idea was simply that special skill and ability should be specially rewarded or compensated for, which in the writer's opinion could be best accomplished by a proper bonus system. However, since any system in order to be a success must be agreeable to the railway shop crafts, otherwise no co-operation on their part could be expected, it logically follows that the piecework system, being objected to by the majority of them, cannot be considered.

The most essential thing today in railroad shops is co-operation between the officials, supervisors and shop crafts. This, combined with loyalty to service will bring out inventive genius and constructive ideas on the part of the mechanics and supervisors.

A Design Which Eliminates Many of the Defects of Ordinary Washout Plugs

ject by J. L. Mohun. The illustration of the washout plug referred to in the letter was not published and it is therefore shown herewith.

NEW BOOKS

Metal Statistics, 1920. 328 pages including advertising, 3½ in. by 6 in., bound in cloth. Published by the American Metal Market and Daily Iron and Steel Report, 81 Fulton street, New York.

This book probably contains the most complete data concerning metal prices and production for many years past that is available in the form of a pocket handbook, and as such the book may be recommended to railroad purchasing agents concerned with metal purchases; although in the present erratic state of the market for all basic commodities, a study of previous price fluctuations would not appear to be of much value as an index to future price levels. The book does not contain any technical information relating to metals. does not contain any technical information relating to metals and is in no sense of the word a text book on metallurgy to be used by students.

TRAVELING ENGINEERS' ASSOCIATION CONVENES

Well Attended Meeting Discusses Operation of Stokers, Draft Appliances and Many Other Subjects

THE Traveling Engineers' Association held its twenty-eighth annual convention at the Hotel Sherman, Chicago, September 14 to 17, 1920. Following the opening exercises the President's address was delivered by G. A. Kell, (Grand Trunk).

Address of President Kell

President Kell spoke in part as follows:

During the great war special efforts were made by each and every man employed in the operation of railroads to conserve coal in particular and to operate the railroads at the lowest possible expense. In this the traveling engineer took no small part. Many of our members have been called on to take up important positions in connection with this matter.

It is just as important today to save coal and supplies as it has ever been. The cost of coal, oil, and supplies of all kinds is greater today than it has ever been before. Therefore there should be no relaxation on our part in any way, but every effort should be put forth to get more skillful operation of the locomotives on the road.

The drastic labor conditions that prevail throughout the country are the cause for great anxiety. There is social, racial, and industrial unrest everywhere, brought about to a great extent by the spirit and practice of profiteering and the high cost of living. Strikes have taken place; in some cases they have been due to over zealous, self-appointed labor leaders more than to anything else. The traveling engineers, whose conservatism and loyalty have never been questioned, who are scattered throughout the different parts of the country and who come in contact with a great many railroad employees, can do much toward influencing the rank and file of the men toward taking the right view of the present critical conditions. If ever there was a time in the world's history when calm and cool judgment should be exercised, now is the time.

OPERATION AND MAINTENANCE OF LOCOMOTIVE STOKERS

Because the stoker is comparatively new to the men, the organization of proper terminal inspection forces has been neglected on many roads. It is considered sufficient to assign a few mechanics to the task of working up the reports made out by the engine crews. A great deal of essential work is re-

ported by the engine inspectors which was not found by the enginemen, and it is but natural to assume that without an inspection of the stoker by a competent inspector this machine will be allowed to continue in service many trips when in need of repairs. The stoker inspection force should be modeled along the lines of our present air brake inspection, and when this is done we will notice a large decrease in the number of so-called stoker failures.

There should be a man at each terminal who is held personally responsible for the condition of all stokers, and he should have a sufficient force of mechanics under his supervision to properly maintain and inspect the number of stokers handled. We can never hope to give stokers the attention deserved while we depend on a busy roundhouse foreman to give them what attention he is able to spare from his other duties.

When an engine arrives at the terminal or cinder pit track, there should be an inspector whose duty it is to run the stoker and observe all features of its operation, both from a mechanical viewpoint and also the manner in which it performs its various functions in order that any defects existing may be corrected before the engine is called to leave. Inspections which are left to be performed on the outgoing track often mean defects, cannot be corrected without delaying the engine, and as a result the engine is permitted to go without the work being done.

In most cases many important parts of the stokers are placed below the engine deck, and no attention is paid to the accumulation on them of coal and grease, with the result that it is nearly impossible to determine just what the machine looks like. If the machine is allowed to become buried, the roundhouse forces have good grounds for presuming that it is not of much importance and they lose interest in its upkeep.

MAINTENANCE

On the question of maintenance organization your Committee does not feel that any fixed rules can be laid down, as this is a matter which must be determined by local conditions and the number of stokers in service. The one vital point is that the organization must be such as to assure the maintaining of the stokers in good operating condition at all times.

Power being the first essential to operating the stoker, the

power plant should not be allowed to get in condition where it cannot furnish ample power to operate.

On stokers using fixed distributors it is essential that these be maintained to their original design, and not be allowed to become burned off, as under these conditions proper distribution of coal over the grates cannot be obtained.

On stokers using a movable mechanical distributor it is equally important that this be kept in good condition, and lost motion not allowed to develop.

When an engine goes into the shop for heavy repairs, the stoker should be removed from the engine and receive the same careful attention and overhauling which other devices

in this connection is to see that pipes are not allowed to remain stopped up for many trips at a time or that pipes are allowed to run with leaks in them which prevent the oil getting to the bearings.

OPERATION

In the preparation of fires for the road, too much care cannot be taken in order that the stoker has a fire in proper condition on which to start firing. The stoker is only a machine, and not an automatic one. It will do only what it is made to do by human hands, so if the fireman starts it to work without having first put the fire in proper condition the

get at such times, in order that when the engine is returned to service the stoker will be physically fit for the arduous duties it is called upon to perform.

LUBRICATION

The practice of equipping stoker-fired engines with a separate lubricator for oiling the steam cylinder of the stoker engine has been tried out with success, and the Committee recommends that this receive consideration. It has been found that this method not only excites more interest on the part of the fireman in the care of the machine, but also is an education to him in the operation of lubricators which he will be called upon sooner or later to handle.

Many parts and bearings of the stoker depend on oil cups for their lubrication, these cups oftentimes having pipe connections to the parts affected. If these cups are allowed to be taken off of the engine or be lost, the parts will run without oil and before this is detected, will be worn to such an extent as to require renewal. Another very important feature

stoker is in no way to blame for a poor performance. In the preparation of fires at terminals, hand firing only should be used. All banks should be leveled off by using the rake and the fire be allowed to burn through uniformly over the entire grate area before using the stoker. Many delays due to having to clean fires on the road are caused by no other reason than that the fireman did not get his fire in condition before starting and a clinkered fire was the result. Light fires are recommended for stoker-fired engines, but whether the fires are light or of medium thickness, it is necessary that they be burned uniformly over the grates before starting.

After starting, the fireman should endeavor to starve the conveyor trough whenever this is possible, as this will enable him better to observe any foreign matter which might enter the trough with the coal. Practically all firemen have been instructed and are practicing the art of starving the fire while the engine is working, and this method of firing has proven entirely satisfactory.

Firemen should be able to foresee the steam requirements

of their engines and maintain an even steam pressure with regular operation of the stoker, rather than run the stoker fast for a few minutes and then stop until the fire has burned through. The latter method is very wasteful of fuel. The use of the stoker to replenish the fire when rolling down grade, standing on passing tracks or when switching, should be discouraged, as the fireman should avail himself of these opportunities to become acquainted with the condition of his

with the slides in the back of the tender open and the trough become jammed with coal during this operation. The fireman should not wait until the engine is detached from the train and about to reach the cinder pit before closing the slides over the conveyor trough, for in this case he wastes the coal by putting it into the fire-box when it is not needed and makes the task of the fire knockers much harder than it would be otherwise.

Wonderful progress has been made in the economical handling of stokers in the past two or three years. The present-day stoker is efficient and economical in its performance when given the proper care and skillful handling.

The report was signed by I. T. Burney, chairman (Southern); O. W. Detrick, (L. V.); J. H. Harry, (Wabash); C. M. Freeman and W. A. Larick, (N. Y. C.).

Discussion

The lubrication of stokers was the point most generally discussed. Many of the members recommended the use of a separate lubricator for the stoker engine placed on the left side of the boiler head where it can be regulated by the fireman. While good results have also been obtained by the lubrication of the stoker engine from the main lubricator, the separate lubricator has the advantage of placing the entire stoker in the hands of the fireman, increasing his interest and preparing him for greater responsibilities on promotion.

In answer to questions which were raised as to the advantages of the stoker as compared with hand firing, the fact was brought out that in very few cases are hand fired and stoker fired locomotives of the same classes in service to permit directly comparable tests. While such tests as have been made by members of the Association indicate an increase in the coal consumption per locomotive mile this has been accompanied either by an increased tonnage, increased speed or both. In one case mentioned the increase in speed has been an important factor in reducing the average time of freight runs over the division from 15 and 16 hours to about 7 or 8 hours. The importance of carefully training stoker firemen was touched on by several members. The points most needing attention in this respect are care in cutting down the rate of coal feed to the minimum; that is, "starving" the trough, and the judicious use of the shovel in building up fires for the stoker and in keeping them trimmed. The reliability of the stokers now in service was quite generally testified to, very few failures occurring which are legitimately chargeable to the machine.

BY-PASS RELIEF AND DRIFTING VALVES

The subject covers three distinct appliances used on locomotives, all of which, though differently constructed, tend to serve practically the same purpose. This is the elimination of vacuum in the steam chest and cylinders and the prevention of the suction of smoke-box gases through nozzle tips into the steam chests and cylinders, which tends to destroy lubrication when the throttle is shut off and the engine drifting.

By-pass and drifting valves are used only on piston valve engines, while the relief valve is used with the slide valve as well as the piston valve.

RELIEF VALVE

The relief valve opens direct communication between the steam chest and the atmosphere when the throttle is closed, admitting air into the steam chest at atmospheric pressure, this air being admitted to and exhausted from the cylinders the same as steam when the engine is drifting. In this way the vacuum created by piston action in the cylinders is destroyed.

On saturated engines, either of the slide or piston valve

Summary of Test Results Showing Vacuum and Mean Effective Pressure Obtained With Throttle and Drifting Valves

fire. Firemen should not be allowed to speed up the stoker in an attempt to build up certain parts of the fire but should use the shovel for this purpose.

When any foreign matter gets into the stoker the fireman should try to locate and remove it, rather than to try to force the obstruction through the machine.

When delivering an engine at the terminal all coal should be allowed to run from the conveyor trough and the slides should be closed in order that the engine will not be coaled

type, this valve is of advantage for the reason that in its absence the vacuum created in the cylinders by the piston action would be filled with smoke and gases from the smoke-box. It is well known what that means to lubrication. However, with the advent of superheat it was soon realized that air must be excluded from the steam chest and cylinders due to the high temperature developed in the steam chest and cylinders by the superheated steam. This valve is a detriment on superheated engines, except possibly on mountain roads where engines drift for miles at a time and are cushioned by means of the throttle. When the superheater damper is closed the engine will work saturated steam so where the damper can be regulated to drop with still enough steam to cushion the engine for some distance the saturated steam will soon cool the cylinders down so that the engine may be shut off. On long and heavy grades this will not only save fuel, but be a factor of safety that is worthy of consideration. When engines are cushioned by means of the throttle, it is essential that all lost motion be taken up in the throttle rigging and that it be sensitive so that the engineer can judge just what he is doing.

BY-PASS VALVES

There are a number of different types of by-pass valves, but practically all function the same. They are held closed by steam pressure when the engine is working steam, and when the engine is drifting the by-pass valve opens and establishes communication between both ends of the cylinders and the interior of the valve chamber, thus equalizing the pressure. Theoretically the principle of this valve is good, but experience shows that it does not always work out in practice, as the speed of the engine, the size of the cylinders and the area of the by-pass valves are factors that govern how effectively they fulfill the claims made in their behalf. The fact that they destroy compression, which many authorities on locomotives feel is essential to take care of the reciprocating parts when the engine is drifting, has caused some roads to discard them. However, there is a vast difference of opinion on the advantages and disadvantages of both the by-pass and the relief valve on piston valve engines; some roads are doing away with the relief valve and retaining the by-pass valve, others are doing just the opposite, others are doing away with both and still others retaining both.

DRIFTING VALVES

With the advent of superheat on locomotives it was soon realized that air must be excluded from the steam chests and cylinders. As a result, many forms of drifting valves have been developed and are now in use.

The function of the valve is to admit sufficient steam to the cylinders when the throttle is closed and the engine is drifting to prevent the formation of a vacuum in the steam chest and cylinders. Some of them are applied to the steam chest or steam channel, others to the cylinders direct; some are automatic and others are operated mechanically. In those applied to steam chests or channels, the steam admission to the cylinders is controlled by the main valve and if drifting is done at too short a cut-off the amount of steam admitted is of such a small volume that expansion may bring the pressure below that of the atmosphere, in which case a partial vacuum would be created which would tend to draw smoke-box gases into the cylinders. Therefore it is better to have the drifting valve attached direct to the cylinders.

DRIFTING VALVE TESTS

The St. Louis-San Francisco ran a test of about 1,400 miles on a passenger engine having 26½-inch by 28-inch cylinders and 73-inch driving wheels over a 238-mile passenger division which has many heavy grades, making it necessary to drift the engine frequently. Two different types

of drifting valves were used and a number of cards were also taken with the drifting valve shut off and the engine cushioned with the throttle.

Valve A is a homemade device. It consists of two differential pistons with a piston valve attached to the operating piston, which admits boiler pressure on top of the other differential piston when the engine is working steam, to keep this valve in closed position. When the throttle is shut off the differential valve with operating piston is moved up by boiler pressure under the small end of the operating piston. The movement of this differential piston allows steam to exhaust from the top of the second piston, raising it from its seat and allowing steam from the dome to pass into the steam chest. The size of the steam pipe from the dome to a point back of cylinder saddle is 1½ in., where it connects with a tee, and from this point to the drifting valve 1¼-in. pipe is used. The 1½-in. pipe has a globe valve at the dome. When the engine stops, steam is admitted to the top of the differential with the operating piston through a pipe connection in the steam chest, moving it down and carrying the valve with it. This admits steam on top of the second piston, closing the valve. This valve is supposed to work as soon as the throttle is closed.

Valve B, which is a commercial device, has similar steam pipe connections, with the exception that the pipe from the tee connection to the valves is 1 in., and it consists of one large differential piston. When the engine is working steam the differential piston is held down, covering the steam port opening from the pipe to the steam dome. When the throttle is shut off, the vacuum moves the differential piston, opening communication between the steam pipe and steam chest and allowing steam to pass direct from the dome to the steam chest.

On the chart the solid lines show the results obtained by Valve A, the dotted lines Valve B and the dash and dot the throttle drift. During the test Pennant valve oil was used. The lubricator was set at five drops per minute to each valve and one drop to the air pumps. The oil was measured at the end of the trip and it amounted to an average of three pints per trip of 238 miles or about 79 miles to the pint. Piston rods were watched closely during the test, always showing good lubrication. The cylinder heads were removed after the test of each valve and were found to be free from carbonization and well lubricated.

During the test with both types of drifting valves the throttle was shut off completely, the same as would be done with a saturated steam engine, anywhere the train would roll and make the time.

While there was not an indicator card taken that did not show some vacuum, it is evident from the way the engine was lubricated that there was an advantage gained by the use of either type of drifting valve. Further, it can be seen that the best results were obtained with both valves at a 25 per cent cut-off. At this cut-off the mean effective pressure was the greatest and the vacuum the least. The throttle drift at 20 per cent and 25 per cent cut-off showed no vacuum, but the mean effective pressure was rather high for good practice. The 50 per cent throttle drift shows a vacuum which indicates not enough mean effective pressure, demonstrating that where the throttle, its rigging or the engineer's judgment are not of the best, results are likely to go from one extreme to the other, either of which is detrimental.

A drifting valve must be so designed as to take care of the worst conditions that can arise, which is generally admitted to be a combination of high speed and short cut-off, as it is under such conditions that the greatest damage is done. A drifting valve to be effective should automatically close when the engine is working steam, automatically open the instant the throttle is closed, and automatically close when the engine comes to a stop. It should have as few working

parts as possible, and these should be properly cushioned or otherwise protected from shocks due to rapid fluctuations in pressure.

The report was signed by J. D. Heyburn, chairman (St. L.-S. F.); A. G. Newell (E. P. & S. W.), N. Suhrie (Penn.), W. Sharp (G. T.) and D. C. Dickert (Sou.).

Discussion

Considerable difference of opinion was expressed as to the cause of carbonization in the cylinders of superheater locomotives. While the flash temperature of the cylinder lubricating oils used with superheated steam is low enough so that carbonization might be expected when air is admitted to the cylinders following the closing of the throttle, as it would be through a release valve, the experience of some of the members seems to justify the opinion that, practically, carbonization is much more likely to be due to deposits from the front end gases drawn into the cylinders through the exhaust passages when drifting with neither relief nor drifting valve equipment.

The Whalen combined relief and by-pass valve was referred to and it was described by the inventor. Two of these valves are installed, one in pipe connections, leading from each port passage to the live steam cavity of the valve chamber. When drifting, the valve automatically opens the by-pass connection and at the same time opens a passage to the atmosphere, the area of which can be adjusted. The usual adjustment calls for 50 per cent by-pass and 50 per cent relief valve action. A service of two years has indicated a material saving in repairs to reciprocating parts and in cylinder packing renewals, and no difficulty has been experienced from carbonization.

Several cases were mentioned where comparisons between engines equipped with by-pass valves or relief valves and others unequipped have demonstrated the need for some such equipment. Without it cylinder packing, valve packing and rod packing all gave trouble while with it this trouble was eliminated and the life of the packing materially increased. The difficulty in lubricating the low pressure cylinders of locomotives when drifting was mentioned. Where using the drifting throttle it has been found that a reduced cut-off is necessary to permit the building up of sufficient pressure in the receiver to properly carry the lubricant into the low pressure cylinders.

The drifting throttle was the subject of much of the discussion. In fast passenger service on the New York Central it is the practise to ease off the throttle in making stops, but not to close it until the speed has been reduced to 15 miles an hour. Many back end main rod failures are attributed to the severe pounding resulting from a full closure of the throttle at high speed. Other members also advocated the drifting of all locomotives with steam admission, but this practice was objected to by others because of the difficulty of properly regulating it. In closing the discussion, J. B. Heyburn, chairman of the committee, commenting on the practice of drifting with steam admitted through the main throttle, did not question the ability of some men to get good results, but considered that the average man is not sufficiently skillful to do so. He therefore advocated the development of some form of drifting valve which would operate automatically.

WHAT ARE THE MOST SUITABLE DRAFT APPLIANCES?

The most suitable draft appliance is that which will produce the required draft with least back pressure under the varying conditions of locomotive operation. That such draft be developed uniformly is greatly to be desired in order that cinder losses may be reduced and the mixture and chemical union of gases in the fire-box improved, and also because the peaks or maximum efforts of intermittent draft are

largely responsible for the plugging of flues; the loss in superheat caused by obstruction to the flow of gases in the superheater tubes frequently being as high as 32 per cent.

Development of draft apparatus which gives promise of approximately complying with these requirements has been under way during the past year or two and should be encouraged; but for the immediate need we must confine our efforts to the fixtures at hand or easily obtainable. The required draft in many instances is less than that which will develop the maximum evaporation. Engines in switching service or regularly in light work of other nature may often be run successfully with draft appliances which demand less back pressure than would be required if the same engines were engaged in more severe continuous work.

While the cinder losses will average approximately 6 per cent of the fuel burned, these losses frequently increase to from 18 per cent to 23 per cent during the period of maximum effort. However, the amount of fuel used per unit of work done decreases rapidly and consistently as the tonnage per train increases toward a reasonable maximum. Therefore, in general, the draft appliance should be so constructed as to provide for satisfactory performance at maximum capacity of each locomotive, and fortunately such arrangement will be found as generally satisfactory as is possible with present apparatus during periods of lighter work.

Section III Committee Report

Results of a series of nozzle tests were recorded briefly in the report of the Committee on Fuel Economy and Smoke Prevention at the June convention of the American Railroad Association, Section III, Mechanical.*

This committee summarized the results of these tests and its conclusions as follows:

"They indicate that under the conditions peculiar to this test with a nozzle having four internal projections it was possible to obtain a higher equivalent evaporation per hour with less back pressure than with a circular or rectangular nozzle having approximately the same net area.

"Your committee does not consider the information now available sufficiently complete to justify positive conclusions as to the most efficient shape of nozzle, and is only in position to report that the circular form of nozzle does not result in the highest vacuum and the least back pressure. As to what form will produce those conditions it is impossible to say without an extended investigation involving a long series of test plant observations.

"It seems evident, however, that all preconceived ideas of exhaust jet action must be revised to agree with the apparent fact that the best results will be obtained when the jet contour is interrupted, as is the case both with the internal projection nozzle and with the one having one axis longer than the other."

The increased draft obtainable by use of the four internal projection nozzle is said to be due to the increase in gas entraining capacity which results from breaking up the continuity of outside of exhaust steam column, thus increasing the surface of the steam jet with which the smoke-box gases may come in contact and promoting the intermingling of these gases with the steam jet.

Indicator cards taken during tests with the internal projection nozzle illustrate clearly that at low temperature the steam does not flow so rapidly as at higher superheat, that with low superheat there is higher back pressure and also a lower initial cylinder pressure even when the steam chest pressure is higher for low superheat than for high superheat. This increase in rapidity of flow due to superheat accounts for the "snappier" exhaust of the superheated locomotive; and as the amount of draft depends, among other conditions, on the length as well as the speed of exhaust jet, it might appear that a reduction of nozzle size should

*See the *Daily Railway Age* for June 11, 1920, page 1705.

accompany the superheating of a locomotive. However, this has not been found necessary in many instances and a conclusion that draft appliance details, including size of nozzle tip, when most suitable for locomotive using saturated steam, should not be changed when superheating apparatus is installed, is sustained by carefully conducted tests at the Pennsylvania Railroad testing plant at Altoona. We are justified, therefore, in using smaller nozzles with superheated steam than were most suitable for saturated steam only as a last resort.

The Basket Bridge Nozzle

Attention is also invited to the nozzle tip arrangement in use on a large number of New York Central locomotives which consists of the usual circular nozzle provided with a so-called "basket bridge," consisting of two splitters set at right angles with each other with the point of intersection directly over the center of nozzle, the splitters being arched

Basket Bridge Exhaust Tip Used by the New York Central

to $1\frac{1}{4}$ in. above the tip at the center. This device is giving very satisfactory service, the use of splitters so arranged having made it possible to increase the effective nozzle opening very materially above the required opening of the plain circular nozzle tip. Engines so equipped give splendid performance, both from capacity and fuel economy standpoints.

N. & W. Tests

In the June, July and August, 1918, issues of the *Railway Mechanical Engineer*, there appears a series of articles written by H. W. Coddington, engineer of tests of the Norfolk & Western, giving accurate and valuable information obtained from extensive tests under most carefully arranged conditions in road service. The experiments indicated clearly the possibilities for improvement in draft and loco-

motive performance by variation from the standard practices and appliances which have been in use for years. These tests also show conclusively that by increasing the external surface of the exhaust column, thus affording greater opportunities for contact of this steam column with the front end gases, that material improvement in draft and locomotive performance can be obtained.

The results recorded were obtained during tests with Norfolk & Western engine No. 100, class "K-1" 4-8-2 type. The original nozzle was 7 in. in diameter with $9\frac{3}{8}$ -in. splitter, and a free area of 35.86 sq. in., 18-in. stack and $26\frac{1}{2}$ -in. inside extension. As a result of experiments the stack was changed to one of 24-in. in diameter, with $26\frac{1}{2}$ -in. extension and 14-in. diameter annular waffle iron nozzle, with effective area of 49.35 sq. in. The steaming capacity was improved; exhaust pressure with the circular nozzle and splitter was 10.94 lb., with the waffle iron nozzle, 4.54 lb.; front end draft with the circular nozzle and splitter was 8.91 and with the waffle iron nozzle 8.63 in. of water, and the locomotive under the decrease in back pressure developed approximately 140 additional horsepower. Using the very conservative figure of $5\frac{1}{2}$ lb. of coal per indicated horsepower per hour, this shows a possible saving of 770 lb. of coal per hour, while the locomotive is working at the rate maintained during the test runs.

Mr. Coddington very recently advised us that the front end arrangement described has been applied to the U. S. R. A. Mountain type locomotives, N. & W., class K-2, with as great resultant benefit as was observed in the K-1 class.

The Theory of Draft Action

Supplementing the conclusions on this subject, as stated by the Committee on Fuel Economy and Smoke Prevention, it seems that any change from the plain circular periphery of the steam jet increases its efficiency in producing draft; one reason for this is that a circle being the shortest possible boundary for any given area, if the cross section of the steam column between the nozzle and stack is circular, the column will have less surface area than it would have if its cross section was any other form. The gas "entrainment" theory is supported by all investigation. However, during the Norfolk & Western tests it was found that the best results were obtained when the exhaust steam column struck the sides of the stack 38 in. or 70 per cent of the length of stack, including the extension, below its top. Every traveling engineer knows that when the exhaust does not essentially fill the stack at the top there is a down draft at the locality not filled and therefore both the so-called "entrainment" and piston action assumptions must be considered when studying this most interesting and important matter.

The expulsion of air and gases from the smoke-box by means of a steam jet directed up the stack is accomplished by the steam jet, either blower or exhaust, forcing (not pulling) air and gases through the stack. A steady flow of steam out the exhaust nozzle or blower will produce draft because the outside surface of the expanding column is broken up irregularly into numerous sections or jets which engulf within the column as a whole and pocket against the sides of stack many small portions of the gases in smoke-box or stack, and thus by pushing innumerable small quantities of smoke-box gases out the stack in this manner reduce the smoke-box pressure.

The Multiple Nozzle and Stack

It appears that the Norfolk & Western has gone farther in the right direction than the other experimenters, at least in so far as applications in service are concerned, but in stack investigation they varied only the diameter of the stack and extension and the length of stack extension inside the smoke-box, and they got best results from the longest extension used. Developments made by William Elmer of the Pennsylvania are therefore of special interest. He found by a

long series of tests that best results in draft production, by means of a steam jet issuing from a circular nozzle tip, were obtained when the diameter of conduit or stack was 3.1 times the diameter of nozzle and when the length of conduit or stack is from five to six times its diameter and when the jet first filled the conduit at about the center of the conduit. Obviously, it is impracticable to provide a modern locomotive with a stack from 10 to 12 ft. long, but by exhausting through several nozzle tips suitably placed below a stack containing a nest of conduits he was able to accomplish a working basis for the desired dimensions within clearance limits and to increase the effective nozzle opening 30 per cent as compared with that of the largest single circular nozzle which it had been possible to use. The multiple nozzle and stack also materially increase the draft.

It does not require exhaustive thought to determine that a stack can be too short and that a stack can be so long that friction of gases and steam within it will detract from the benefits derived by having just enough stack length. The multiple nozzle and stack design provides a method for equipping modern locomotives with stacks of sufficient diameter and length and it also provides for an extensive increase in the surface of the exhaust steam column between the nozzle tip and stack as well as for a very material increase in effective nozzle opening.

Some most interesting experiments conducted by the mechanical department of the Big Four during the past year indicate the advisability of maintaining the same average exhaust pressure while a locomotive is operating at maximum capacity during the entire range of speeds, and they have equipped at least one locomotive with apparatus which automatically adjusts the cut-off so as to maintain a predetermined exhaust pressure at all speeds. It is not the intention to discuss this invention, but we urge the installation of back pressure gages on all road locomotives, as knowledge of this pressure will not only aid greatly in improving draft conditions and apparatus, but will enable the engineers to operate locomotives more efficiently.

Distribution of Draft Through the Grates

Even a most efficiently developed draft in the smoke-box will only partially obviate some of the present losses and inefficiency, unless that draft is most advantageously distributed throughout the fire-bed. Use of the so-called checkered arch appeared to be a move in the right direction, but difficulties have arisen in connection with its general use. The standard arch, as usually applied, causes the draft to be applied most severely through the back grates and, to avoid the ill effects of excess air through this section of the fire-bed, firemen have resorted to excessively heavy firing on the back gates. We have decried such practice as wasteful—perhaps without entire justification under the existing unequal distribution of draft.

Draft deflector plates below the grates or variations in air inlet openings through the grates so as to equalize or properly distribute the draft through the fire, seem to be required when the standard arch is used, but because of the difficulties which would be encountered in following either of these suggestions, suitable changes in the location of arch bricks or the reduction of air openings through the rear grates are recommended—preferably the former, for we fully appreciate that the best performance demands the maximum possible opportunity for air to pass through the grates.

The report was signed by H. C. Woodbridge (Loco. Stoker Co.), chairman; W. G. Tawse (Loco. Superheater Co.), W. M. Cooper (Grand Trunk), H. L. Harvey (C. & N. W.), and T. L. Kenney (Big Four).

Discussion

Several members were disposed to question the statement in the report made in referring to the checkered arch, that the standard arch is the cause of the apparently heavier

draft at the back end of the grates, this being explained as due to the tendency for a heavier fire to accumulate at the front end of sloping grates and to the openings at the rear ends through which the grate rigging passes which provide for greater air admission under the rear end of the grate than at other portions. Some difference of opinion was expressed as to the advantages of the checkered arch, although in one case where comparative tests have been made and the coal measured, the fuel consumption has been found to be less with the checkered arch than with the standard arch. The former has also proved advantageous in reducing smoke on switch engines in terminals. The statement was made in the discussion that the basket bridge used on the New York Central in one case made possible an increase in the size of nozzle opening from 5½ in. to 6⅝ in. and that wherever it has been used it has resulted in a reduction in fuel consumption.

The discussion showed a feeling among many of the members that an exhaustive investigation of front end designs in which all factors should be taken into consideration, was very much needed.

In closing the discussion Mr. Woodbridge laid stress on the value of the installation of a back pressure gage in the cab, connected through branch pipes to the exhaust passages of the cylinders. This has been found of value in comparing the draft efficiency of different engines and in providing the engineman with a check both on draft conditions and on his handling of the engine.

THE NICHOLSON THERMIC SYPHON

BY HARRY CLEWER
Fuel Supervisor, Chicago, Rock Island & Pacific

The first application of the Nicholson-Thermic Syphon equipment to a locomotive was made more than two years ago on the Chicago, Milwaukee & St. Paul; this road since then has equipped four more locomotives.

About sixteen months ago the Chicago, Rock Island & Pacific equipped two locomotives, one superheated and one non-superheated, after which an extended and thorough test of this equipment was conducted, comparing these engines with others of the same class but without the syphons.

Test results and subsequent developments in service were of such a favorable nature that a program has been established of equipping ten engines a month in the shops. In addition to this, thirty-five new Mikado, Santa Fe and

Mountain type locomotives now building will be equipped with syphons. This will make a total of 75 locomotives equipped.

It is possible to increase fire-box heating surface from 10 per cent to 40 per cent, depending upon the number and size of syphons used. One, two and three are used, depending upon the width of the box. The syphons form two to four combustion chambers in the hottest part of the fire. This leads to a much better mixture of the liberated gases and air, thus aiding complete combustion. The syphon heating surface is in a position to "see" the fuel bed and flame,

so the transfer and heat to the syphon by radiation is high.

Intake channels enter the neck of the syphon at the throat sheet and extend along the barrel of the boiler nearly to the boiler check. They are simply inverted troughs capable of delivering to the syphon all of the water which will be discharged through the crown sheet opening.

The Rock Island tests showed that the two-syphon equipment on a consolidation locomotive increased the evaporation 14 per cent per pound of coal. A summary of the tests is given in the table and all indications on locomotives equipped since the tests were conducted, verify the test results.

The syphon equipment does not disturb the water level in the water glass. It was noticeable during the tests referred to that the water in the glass was very quiet.

The intake channels do not clog and the scale formation is no greater in the syphon than on the sides and crown sheets. Well located washout plugs make it possible to wash the syphons thoroughly.

Next Year's Officers

The following officers were elected to serve for the coming year: President, W. E. Preston (Sou.); first vice-president, J. H. DeSalis (N. Y. C.); second vice-president, F. Kerby (B. & O.); third vice-president, E. H. Howley (Erie); fourth vice-president, W. J. Fee (Grand Trunk); fifth vice-president, J. N. Clark (Sou. Pac.), and treasurer, David Meadows (M. C.). The following are the new members of the executive committee: J. D. Heyburn (St. L.-S. F.); J. E. Russell (Sou.), and V. C. Randolph (Erie).

GOVERNMENT TESTS OF WATER INDICATING DEVICES

Report of Final Tests and Recommendations Submitted by The Bureau of Locomotive Inspection*

FOR the purpose of determining, if possible, the general outline of the flow of water which evidently existed at the back head, when high evaporation was taking place, tests were made on one of the U. S. Railroad Administration standardized 2-10-2 type locomotives, equipped with five arch tubes and brick arch, extending to within 51 in. of the door sheet; fired with duplex stoker and using bituminous coal for fuel. The test apparatus used in these tests is

of the boiler. It was found during these tests that with the top connection to the water column connected at its original position the column would entirely fill when 4 in. to 5 in. of water was reached in the column glass. When changing from this connection to the highest point on the back head, the water would immediately recede to 4 in., but when changing from one connection to the other on the highest part of the boiler the readings were not affected, which in-

Fig. 3—Water Indicating Devices Used in Fourth Series of Tests

shown by Fig. 3; the sliding tubes illustrated were graduated so that correct readings could be taken.

Fourth Series of Tests

During two round trips many readings were taken while the locomotive was in operation. It will be noted, by referring to Fig. 3, that with 2 in. of water showing in all glasses and one gage of water in the column, the gage cocks applied on the left side of the boiler head in the usual manner indicated full water, while No. 1 tube indicated strong flutter at a 12-inch adjustment, No. 2 tube indicated a strong flutter at a 9 1/4-inch adjustment, and No. 3 tube showed an occasional flutter at the back head, showing a rise of water at the back head of approximately 9 in. above that being registered by the water glasses or existing further ahead over the crown sheet.

The dotted line in Fig. 3 indicates what we believe to be the general outline assumed by the water where it reaches a greater height on each side than at the vertical center line

indicated that dry steam was being obtained both at the back knuckle and further ahead, which was, no doubt, due to the increased dry steam space in the back end of this boiler and the exceedingly good water used in this district.

Fifth Series of Tests

To further determine the approximate outline and proportions of the water conditions existing at the back boiler head, while the locomotive is being operated with heavy throttle, or when steam is being rapidly generated and simultaneously escaping from the boiler, tests were made with appliances shown by Fig. 4, covering a distance of 808 miles, in bad-water districts, on approximately level track and while handling regular tonnage.

The locomotive on which these tests were made was of the heavy 2-8-2 type, equipped with superheater and Duplex stoker, using bituminous coal for fuel. The boiler had a sloping back head, with firebox equipped with brick arch supported by four 3-inch arch tubes, the brick arch extending to within 52 in. of the door sheet and 30 in. of the crown sheet.

The apparatus shown by Fig. 4 consisted of four gage

*The preceding portion of this account of tests recently conducted by the Bureau of Locomotive Inspection of the Interstate Commerce Commission was published in the September issue of the *Railway Mechanical Engineer*.

cocks applied directly in the back head near the knuckle, one water column to which three gage cocks and one water glass were attached, one water glass with a 9-inch reading, standard application, with both top and bottom cocks entering boiler back head direct, one water glass applied for experimental purposes with the bottom cock entering the boiler head on back knuckle and one entering 13 in. boiler head on back knuckle and one entering 13 inches ahead of the back knuckle, and four exploration tubes or sliding gage cocks.

Fig. 4 shows a side elevation of these exploration tubes or sliding gage cocks entering the back head parallel to the horizontal axis of the boiler through suitable stuffing boxes, with a vertical pitch of $3\frac{1}{2}$ in., giving a total vertical reading of $10\frac{1}{2}$ in. with a horizontal adjustment of 24 in. Gradations were marked on these tubes so that accurate readings could be taken and recorded. The lower one of these tubes entered the boiler head on a level with No. 2 gage cock. The lowest reading of all water glasses and gage cocks was $4\frac{5}{8}$ in. above the highest point of the crown sheet.

Fig. 4—Water Indicating Devices Used in Fifth Series of Tests

It will be noted from Fig. 4 that while tube Nc 1 was submerged, tube No. 2 showed a flutter of steam and water at an adjustment of 24 in.; tube No. 3 showed water at an adjustment of 10 in. and steam at $13\frac{1}{2}$ in.; tube No. 4 showed water at an adjustment of $4\frac{1}{2}$ in. and steam at 8 in. These readings were taken while the experimental water glass and water glass attached to the water column registered 2 in. of water, and the gage cocks attached to the water column showed one gage, while the four gage cocks applied in the back head registered full.

The water in the territory where these tests were made is very light and foams badly when compound is not used. About 110 readings were taken with these tubes or sliding gage cocks and other appurtenances used to register the water level. It is impossible to outline this flow of water accurately, as it changes with the operating conditions and the condition of the water in the boiler; but it is believed that this serves to illustrate the general condition which prevails to a greater or less extent in all locomotive boilers, especially those equipped with brick arch and arch tubes, while the locomotive is working heavy throttle or steam is rapidly escaping from the boiler.

It was found that approximately the same conditions were disclosed as those developed in other tests, except that the outline of water reached a higher elevation and greater proportions at the back head than those illustrated by Fig. 3, which is, no doubt, due to the extremely good water used for locomotive purposes in the district where the previous tests were made.

The readings of the water column and experimental water glass could not be varied when changing from one connec-

tion to the other, as was the case in other tests, which we believe was due to the increased steam space in the back end of this boiler; and while the roll of water up the back head reached at times an approximate height of 12 in. to 13 in. above the general water level in the boiler, it did not apparently reach the top connection to these appliances in the back head knuckle.

When foaming very badly, there was slight agitation in the experimental glass when connected in the back knuckle, and occasional bubbles in the glass, but not sufficient to attract serious attention. This agitation was entirely absent when the top connection was made ahead of the back knuckle. With 1 in. of water, or less, the water in the standard glass registered practically the same height as the other two glasses. With 2 in. to $2\frac{1}{2}$ in. of water in the glass, when water was foaming, the water in the standard glass rose 2 in. to 3 in. higher, and there was much agitation and many bubbles in it, while the column glass and the experimental glass connected ahead showed no agitation whatever. With 3 in. or more of water in the standard glass and the water foaming badly, the standard glass would fill, and it was impossible to tell the actual height of water in the boiler by that device without closing the throttle, while the experimental glass and the glass attached to the column continued to register 3 in. or more of water, and the top gage cock, attached to the column, would indicate dry steam when opened in the usual way, and the four gage cocks applied directly in the boiler would register full water.

Observations Made with Light in Boiler

Tests were made on a comparatively small locomotive, used in switching service, equipped with a wagon-top, radial-stayed boiler, having narrow OG firebox and vertical back head, the diameter of the largest course being 59 in. The special feature which should be borne in mind is that no arch or arch tubes were used in this boiler and that the back head was vertical.

The water-indicating devices consisted of three gage cocks spaced 3 in. apart and applied directly in the right knuckle of the back boiler head, with a vertical reading of 6 in., and one reflex water glass with a clear reading of 7 in., and with top and bottom connections entering the boiler head direct on the vertical part 5 in. to the right of the center line. The lowest reading of the gage cocks and water glass was 3 in. above the highest part of the crown sheet.

So that the action of the water could be observed, a glass tube was inserted in the top of the wrapper sheet which permitted the use of an electric light inside the boiler, which clearly illuminated the steam space over the crown sheet. Five bullseye sight glasses were applied over the back end of crown sheet, two over the front of crown sheet and three in the vertical back head, so that the action of the water in this part of the boiler could be seen while under steam pressure. The arrangement of these appliances is illustrated by Fig. 5.

Both main rods were disconnected, cross heads blocked at end of stroke and valve stems disconnected and so placed that steam was discharged through the exhaust nozzle and stack, creating a forced draft on the fire, representing as nearly operating conditions as possible.

When the throttle was closed and no steam escaping from the boiler, the surface of the water was approximately level, with a distinct circulation noted from back to front and from the sides toward the center of the crown sheet. When the safety valves lifted, the water rose with fountain effect, around the edges of the firebox, from 1 in. to 2 in., and the circulation was materially increased.

When the throttle was opened and steam was being generated and escaping from the boiler in greater volume, the level of water throughout the boiler was seen to rise 1 in. to

1½ in., which rise was registered by the water glass. and a marked flow of water, with fountain effect, was observed rising around the firebox at the back head and wrapper sheets, reaching a height above that over the remaining portion of the crown sheet of approximately 2 in. to 4 in., in proportion to the amount of steam being generated and simultaneously escaping from the boiler.

The important feature to be noted is that this height of

Fig. 5—Arrangement of Light in Boiler to Determine Water Conditions

water, as seen at the back head, was approximately 4 in. at its maximum, and was registered by the gage cocks, while at the same time it could be seen that the water glass was registering the level further ahead over the crown sheet.

Among the interesting features observed were the size of the steam bubbles which were approximately ¼ in. to ⅜ in.

Since a difference of 4 in. was observed between the height of water at the back head and that further ahead in this boiler, which had a vertical back head and OG type firebox and was not equipped with brick arch or arch tubes, there can be little question but that in the modern locomotive boiler, which has a sloping back head and is equipped with brick arch and arch tubes, which greatly accelerates the movement of water in this part of the boiler, due to the rapid circulation through the arch tubes and the deflection of heat against the door sheet and back end of crown sheet by the brick arch, this difference between the height of the water at the back head and further ahead over the crown sheet must be materially increased.

General Observations

The feed water which enters near the front end is much lower in temperature than that in the boiler, which, due to its density and weight, naturally lowers and moves toward the firebox sheets where the greatest evaporation takes place. As the water is heated it rises, due to its decreased weight, influenced by the steam bubbles rising to the surface where they explode. This circulation causes a movement of water from front to back in the lower portion of the boiler, and upward around the firebox, and from back to front in the upper portion. This circulation unquestionably takes place with sufficient rapidity to carry the water in the boiler around the firebox sheets above the general water level, due

Fig. 6—Dangerous Condition Due to False Registration of Gage Cocks

in diameter, and the rapidity with which they were seen to rise to the surface and explode. The size and number of these steam bubbles, which were seen rapidly rising next to the back head, explain one of the physical reasons for the increased height of water around the crown sheet and the rapid circulation attained.

These observations establish beyond question that when steam is being generated and escaping there is an upward movement of water at the back head of the locomotive boiler which carries it above that further ahead over the crown sheet, and that the gage cocks, when applied directly in the boiler, register this rise of water and do not indicate the level further ahead, while the water glass registers the level of water further ahead and not the fountain of water at the back head.

to the limited space in the water legs, where the greatest amount of heat is applied.

Fig. 6 illustrates a condition which may exist where the water glass registration is ignored and the gage cocks applied in the boiler are depended upon to register the correct level. Since practically all enginemen have been taught to rely on the gage cocks in preference to the water glass, this is an especially unsafe condition, and is, no doubt, the cause of many damaged crown sheets the reason for which has not been determined.

It is recognized that the volume of water in the boiler increases in proportion to the amount of steam being generated and in the same ratio that the steam bubbles below the surface are formed and expanded, the volume of which depends to a very considerable extent upon the purity of

the water in the boiler and its ability to readily release the steam being generated, consequently increasing the height of water in the same proportion, which height is registered by the water glass.

Since it has been established that gage cocks screwed directly in the boiler do not correctly indicate the general water level, the question arises as to what would be a proper appliance. After careful investigation and tests, it is believed that Fig. 7 illustrates a water column that will afford the safest and most practicable method yet disclosed for accurately indicating the general water level in the boiler under all conditions of service.

Recommended Practice

This arrangement has been recommended by this Bureau and was adopted as recommended practice by the Committee on Standards, of the U. S. Railroad Administration, at its February, 1920, meeting. To this water column three gage cocks and one water glass are shown attached, one water glass applied in the usual manner on the left side of boiler head for the purpose of forming a double check of the

Very recent tests indicate that to avoid the possibility of inaccurate readings, due to raising the water in the column when the gage cocks are opened excessively wide, the inside diameter of the column may be made $3\frac{1}{2}$ in. and that of the top connection 2 in. Experiments with column and steam pipe of these dimensions and the $\frac{3}{4}$ -in. opening in the connection to the boiler at the bottom showed that the water in the column glass could not be raised, by opening the gage cock, to exceed $\frac{1}{4}$ in., regardless of the amount or the length of time the gage cocks were open.

It is recommended that the bottom water glass cock and bottom connection to the water column enter the boiler horizontally, and that the water column and water glasses should stand vertical.

Steam-pipe connections to water columns and water glasses should be made as short as possible, so as to obtain a supply of dry steam at all times, and so arranged as to thoroughly drain and be free from short bends or any possibility of sags or traps. It has been definitely established that where traps or sags that will retain the water of condensation are permitted in the top connection to water

Fig. 7—Recommended Arrangement of Water Indicating Devices

height of water over the crown sheet and to broaden the view from different parts of the cab.

In constructing and applying the water column, the ratio of openings between top and bottom connections, as indicated by Fig. 7, should be retained, and the bottom connection screwed into the boiler far enough to pass all obstructions which may be immediately above them. It was illustrated in the fifth series of tests that when the bottom connection to the column entered the boiler head one inch past flush, and directly under a "T" iron, it caused the water to rise one inch in the column glass, but when extended past the "T" iron, the readings in all glasses corresponded.

The larger connection to the top of the column, and restricted openings in the gage cocks, which should be not more than $\frac{1}{4}$ in. in diameter, are suggested for the purpose of preventing the water from being raised when the gage cock is opened wide, the object being to compensate for the lowering pressure in the column through the larger top connection, the area of the smallest opening of which should not be less than $1\frac{1}{2}$ in. copper pipe, so preferably larger.

glasses or water columns, the reading of the water is materially affected, causing a higher level to be indicated.

It should be borne in mind that when water glasses are in proper condition to correctly register the water in the boiler, the water is never at rest while under pressure, and that when the water becomes slow or sluggish of movement or in agitation, it indicates an improper condition that should be immediately corrected. Such conditions are usually caused by restriction in the openings in the fixtures, sags or traps in the steam-pipe connection, or the top connection made so as to allow water to enter, and sometimes by bottom connection being improperly located so as to cause steam bubbles to enter.

The water-indicating appliances are among the most important devices on the locomotive, from the viewpoint of safety as well as economy; therefore, every effort should be made to see that they are so constructed, applied and maintained as to properly perform their function under all conditions of service, and so that the enginemen operating the locomotive may have the widest and easiest possible view from their usual and proper positions in the cab.

GENERAL FOREMEN HOLD ANNUAL MEETING

Discussion on Methods of Reducing Cost of Equipment Repairs Covered a Wide Range of Subjects

THE problem of selecting and training foremen, the handling of labor, the need for adequate machinery and facilities and the scope of the fusion welding processes, in their bearing on reduction in the cost of repairs to cars and locomotives, were the subjects discussed with the keenest interest by the members of the International Railway General Foreman's Association in attendance at the sixteenth annual convention.

The convention was held at the Hotel Sherman, Chicago, September 8 to 10, inclusive, with President W. T. Gale (C. & N. W.) in the chair. Following the customary formal exercises at the opening session, President Gale delivered his address. An abstract of his remarks follows:

President Gale's Address

Much might be said as to ways in which improvements in railway transportation may be made. Government control of the railroads in the United States has now ceased to exist, and it is natural that the railroad companies should desire to return to improved pre-war conditions. There is a demand for earnest effort at increasing the production of essentials and the markets of the world are ready for our country's productions. As foremen in railroad shops we must do our full part in helping to get results. It may be considered a patriotic duty to serve the country in providing efficient and economical transportation for its citizens and products.

In the supervision of employees, foremen can get the best results by dealing kindly but firmly with all men under their charge. Foremen should not be led astray by any impressions of their personal importance, but must rather be filled with the spirit of fairness to all. The interest of their employers can best be served by a proper understanding not only of the materials which they must handle, but also by securing the effective co-operation of all employees under their supervision. The part of the program pertaining to the proper handling of labor should be fully discussed.

Address by Robert Quayle

Robert Quayle, general superintendent of motive power and machinery of the Chicago & North Western, addressed the association, dwelling particularly on the importance of the general foreman's job to the railroad and to the nation. He drew attention to the fact that the ton mile cost of moving freight on American roads is the lowest of any country in

the world, Japan ranking next. But while our labor cost averages about \$1,600 per man per year, Japan's is only \$174, which is some indication of the efficiency of American methods and American railroad men. The part of the general foreman is particularly important in getting results in the mechanical department because of his close contact with all of the details, which in the aggregate must be properly handled to secure the final result desired.

Mr. Quayle said that railroad men are not wholly responsible for the unrest which has been such a potent factor in bringing about the comparatively low productivity of labor at the present time. Railway employees have been expecting increases in wages since before the war and have long been thinking and talking about little else. The recent wage increase, however, has satisfied most of the men. With the dissatisfaction removed the men are now ready to give thought to their work. Mr. Quayle stated that increased production must be obtained through the general foremen, who must exert a steady continuous pressure on the men to get back to pre-war conditions of output. In doing this, however, it must not be forgotten that they are men and they must be dealt with smilingly and with kindly feeling.

STANDARDIZATION OF ENGINE FAILURES AND TERMINAL DELAYS

The committee will not attempt to define what shall or shall not constitute an engine failure, believing that better conclusions can be arrived at after the question has been thoroughly discussed.

"Time cards do not provide for failures, so why have them? While it may be true that there are many failures, let us all try to avoid them if possible, and not make a standard of them, no matter how great or small they may be," says one master mechanic, in writing to the committee.

The following is the line of procedure followed by some roads when an engine failure occurs:

All information relative to the failure is secured from operating officers on division on which failure occurs. Mechanical officers at the division point secure all available information from the engineer, which is also supplemented by a written statement from the engineer.

If, in the opinion of the party receiving the statement from the engineer, the failure was due to improper handling of the locomotive by any member of the crew, the superintendent is requested to have an investigation made by road foreman. If the engineer contends that the failure was due to the engine, or if the work as reported was not properly performed at the terminal from which the engine was dispatched, the party in charge at that terminal is required to make a statement. The engine inspector is required to inspect all engines and check his inspection against the work report of the engineer. He is further required to know that this work was performed in a satisfactory manner before the engine leaves the terminal. The men performing the work are all questioned as to the manner in which the work was performed, and the decision is then made as to whether the work was satisfactorily completed.

In the event of the failure of the parts of a locomotive, the broken parts are collected and delivered to the mechanical engineer for his opinion as to whether the defect was caused by a flaw in the metal, overheating, lack of lubrication, etc. If caused by a flaw, steps are taken at once to secure a statement from the terminals between which the engine has been operating as to what has been observed by inspectors or reported by the engineer. If, in the opinion of

of high standing, as to what should be considered an engine failure:

"I do not consider that a break down of less than five minutes should be called a failure. Where there is a delay of five minutes or more and the engineer picks up the time that he has lost in fixing up the engine and arrives at the terminal with no loss of time, this should not be classed as failure. Where an engine has been in excessive duty on the road and the fire gets dirty so that it has to be cleaned in order to complete the trip, I do not consider this is an engine failure, but a transportation failure due to holding engine too long in service.

"Again, a man might frequently stop along the road when he notices a back end of the main rod heating, to ease up the keys, making a delay of probably five minutes, and starting up with his train again and picking up the lost time. This is done to avoid a failure, but in a great many cases it is classed as a failure. At times the train crew sets the brakes from the caboose, pulling a drawbar out of the back of the tank or breaking the drawbar between the engine and tank. This is classed as a failure, but it should not be.

"What should be classed as a failure is an engine failing through leaky tubes when put in excessive service, losing time on the train that she is on, or when any material breaks,

W. T. Gale—C. & N. W.
President

G. H. Logan—C. & N. W.
2nd Vice President

William Hall—C. & N. W.
Secretary-Treasurer

the mechanical engineer, the defect was caused by improper construction, he will change the design.

In the event of a failure due to the engine not steaming, the quality of the coal is taken into consideration and the engine's front end, fire box and flues are thoroughly inspected. If flues are stopped up, it is evident that the terminal from which the engine was dispatched is at fault and corrective measures are taken. If failures are due to improper firing or mishandling of the engine, the corrective measures are taken through investigation by the road foreman of engines.

Train dispatchers make four copies of each engine failure report. The superintendent sends one copy to the general superintendent, one to the assistant mechanical superintendent, one to the road foreman of engines, and retains one copy. This report is checked against the engineer's report. If the road foreman of engines considers an engine failure unjustly charged, he writes the superintendent, giving his reasons, and if the superintendent finds that the failure has been charged without cause, he cancels it, using regular report blanks for that purpose and sending copies to the general superintendent, assistant mechanical superintendent and the road foreman of engines.

The following is the personal opinion of a railroad officer

being defective in itself or in the workmanship, and causing a delay to exceed five minutes; in fact, any defect that is due to the engine."

Meetings should be arranged at frequent intervals when engine and train performance can be discussed freely and wrong practices corrected. The mechanical department should be advised at the earliest possible moment as to what power may be required, thus giving them time to make necessary preparations.

The members of the committee were Wm. Hall (C. & N. W.), chairman; J. R. Harrington (M. K. & T.), M. H. Westbrook (G. T. W.), H. E. Venter (Sou. Pac.), and W. Mulcahy (B. & O.).

Discussion

From the variety of definitions as to what constitutes an engine failure which were given by those who took part in the discussion it seems evident that a direct comparison of engine failure records can scarcely be made on any two railroads in the country. Not only is this true but practices differ in many cases on different divisions of the same system. The desirability of uniformity in the definition of what constitutes an engine failure, particularly on the divisions of the same system, received considerable attention.

Where practices differ, comparisons lead to unjust criticism and have a demoralizing effect on the organization. On the other hand, where the practice is uniform and just comparisons can be made, a spirit of competition to see which division can make the best record may be readily developed. Some of the members felt that efforts should be made to develop a standard for application on all railroads in order that direct comparison might be made between different systems. The effect that different operating conditions should have in establishing the definition was touched on. On a train making local stops, where frequently opportunity is offered to look after the locomotive, a rule that delays be charged whether made up or not is entirely different in its effect than when applied to fast non-stop runs, where it may be necessary to stop the train in order that an adjustment may be made to prevent a complete engine failure later. By comparison, however, injustice is done if such a delay is charged against the engine when the time has been made up before reaching the terminal.

It was also suggested that engine failures should be charged against shop points rather than to divisions. The reason for this is that passenger runs frequently operate over the lines of two or more divisions, the intermediate divisions, however, having no jurisdiction over the power. To charge a failure under these conditions to the division on which it happens to occur leads to unjust comparisons and provides a record which is of no value as a guide to corrective measures.

REPAIRING SUPERHEATER UNITS

Superheater units become worn at the front end between the bends and the ball joints. After considerable study and trial, it was found that the best method of repair is first to determine if unit is worn through to cause a failure, or so that they will not last until another shopping. If they pass this inspection, then apply a hydrostatic test of cold water up to 400 lb. While under this pressure the inspector should hammer test parts which show corrosion, especially around the return bend. If the return bends leak, and are worn too badly, they can be repaired by acetylene welding. If worn, there are two ways to repair them economically.

On the old style units the tubes can be cut off with acetylene next to the bend, rethreaded and new bends applied. The new units should be cut off at the return bend with acetylene on an angle of 45 deg., and then by the aid of two air cylinders, with the jaws facing each other, press the ends of the unit, heated to a cherry red, together to form a bend. Then weld the tubes together, using plenty of material to reinforce them on the flat surface and on the end of the bend. After this is done, again apply 400 lb. hydrostatic pressure and hammer test.

To repair the ball joint ends of units, they should be cut off back of the bend, say five to eight inches, with acetylene gas and then belled out to half the thickness of the tube, back $1\frac{5}{8}$ in. To make the new ends, the balls are forged on each end of a piece of tubing. This is done in two operations of the forging machine. After being forged the ball joint is turned on a turret lathe and the tube is cut to whatever length is desired, the end being turned to fit the ball end of the tube. These new ends can be made 50 or 100 at a time, machined, ready to apply, and can be distributed to roundhouses or other than main shops which will save considerable time in getting power into service. After the new end is ready, it can be welded by acetylene in a few minutes. The 400 lb. hydrostatic pressure should then be applied to test the unit. After unit is tested, band should be applied and spot welded on each side by the electric or acetylene process to keep the band from slipping. This need not be over $\frac{3}{8}$ in. in diameter and $\frac{1}{8}$ in. high.

To get the best results in reapplying superheater units to header, the ball joints should be thoroughly cleaned and

polished with emery cloth. The joint should then be tried with a standard gage, and if found to be out, should be ground with a mixture of oil and cut steel, using a soft metal grinding form and a small air motor. If joints are badly damaged, they should be trued up with a milling cutter and then ground with oil and cut steel. The joints on the header casting should be thoroughly inspected, and if found to need machining a milling tool opposite to the one used on ball joint should be used, and then ground with oil and cut steel, using a form the same shape as the milling tool. Slots in the superheater header should be carefully inspected to see that they are free from sand or scale and have a square sur-

Method of Renewing Ends for Superheater Units—A. T. & S. F.

face, and that the bolt heads are square, so that there will be no chance of the bolts slipping. Threads on the bolts should be carefully examined and if found to be elongated, they should not be used. Steel bolts with strength of not less than 74,000 lb. should be used. After superheaters are applied, they should be pumped to the steam pressure of the boiler and thoroughly inspected to see that all joints are tight.

Methods Employed on the "Big Four"

Two plants are used for the repairing of superheater units. The plant in the machine shop consists of a reservoir 30 in. by 36 in. which contains two-thirds water and one-third air when charged for service. There is a hydrostatic pump and gage in connection with this reservoir and a sealing cylinder used for sealing the ends of units when testing. A three-way valve having seven ports, is specially designed to complete the entire operation of testing by three movements or positions. These positions of the valve admit air to the unit from the main reservoir to charge and seal the unit; this is the first step taken in this operation. The next is lap position which is also the exhaust position and the other position is known as water position.

The sealing cylinder is specially designed to seal both ends of the unit and form an unrestricted communication between the main reservoir and atmosphere at the lower end of the operating valve. It is provided with a "T" head piston, hollowed out to slip over each unit, coming in contact with the back of the unit head, bringing it against the rubber insertion in the bottom head of the cylinder. The operation is as follows:

Air is admitted to the unit by placing operating valve in "air" position, the air passing from the main air supply through the operating valve, the unit and into the main reservoir. As the air passes through the sealing cylinder the piston is raised by air pressure and seals the unit to the cylinder. Pressure is allowed to accumulate in the main reservoir and unit. The operating valve is then placed in the water position and the exhaust valve under the operating valve opened, allowing air from the unit to escape to the atmosphere. The air pressure in the main reservoir forces water into the unit when the air is released. When water shows at the exhaust port, it is then closed and the hydrostatic pump applies 350 lb. pressure. To release the water from the unit,

the operating valve is placed in the air position, the valve on the main reservoir is opened to allow the pressure to escape and air from the line drives the water back into the main reservoir, leaving the unit free from water. Air from main line is then closed, the exhaust valve opened and unit unsealed.

For repair of units which are bent, at the opposite end of this unit table are two air cylinders placed vertically, one placed over the other, but having separate pistons. The upper cylinder is provided with a continuous piston, traveling through both heads, and is used as a ram to give the bottom cylinder a blow when the air pressure in the lower cylinder is insufficient to straighten the bend in the unit. The lower cylinder also has a double end piston that gives the upper cylinder contact outside of the cylinder. The lower cylinder is used as a squeeze to straighten all four lines of the unit pipes at one time, these lines being separated by sheet metal shims laid horizontally and vertically, adjusted near the point where the piston of the cylinder comes in contact with the unit, properly spacing the four lines of pipe.

If leaks develop under hydrostatic test, these leaks are thoroughly sand blasted, removing all carbon and scale, and the leak is repaired with the acetylene torch.

A portable testing outfit is provided that can be taken to places throughout the shop where units have been removed for testing and grinding only. On either of these plants, the actual time taken for testing a unit is not over two minutes.

In the heavy repair plant, located in the boiler shop, there is a forging machine, with suitable dies for renewing the return bends, and a similar testing plant to the one mentioned above. There are also metal cutting saws for sawing off defective return bends, a sand blasting device for removing all foreign matter from the ends of the units, and a reaming device for reaming the ball ends of the units to the proper radius, preparing them for grinding.

From past experience it has not been profitable to use header bolts with a tensile strength less than 74,000 lb. These bolts are tested for elongation by gaging the thread.

The first superheater equipment was applied in July, 1911, and it is impossible to give the average life of units as the first ones applied are still in service. Units are not scrapped due to loss of weight. The use of micrometer calipers has indicated that the deterioration of the unit is very uniform, there being scarcely any variation between the front end and back end of unit. The most common failures are right at the end of unit where it comes in contact with cinders, and where it is subjected to the greatest temperature. When renewing return bends only enough is cut off to renew the bend. It is not necessary to make any sacrifice in the length of tubing because of the deteriorated condition of that part of the unit.

The report was prepared by the following committee: W. L. Jury (A. T. & S. F.) chairman; J. E. Stone (Sou. Pac.), J. Martin (Big Four), E. P. McDonald (Sou. Pac.) and C. L. Walters (Gt. Nor.).

Discussion

There was considerable discussion of the methods of taking care of header joints. While much of this dealt with the ball and cone joint it developed that a number of roads still use only the ball socket joint in the header. In the discussion on methods of grinding the ball and cone joints, a question was raised as to the necessity of grinding this type of joint since it is evident that the ball has a line joint in the header. With the ball drawn up tight this is bound to crease the joint and a great deal of care in grinding seems unnecessary. It has actually been found unnecessary to grind the joints more than just to clean them up. On the Grand Trunk where this practice has been followed, only two units have been found to leak out of 800 tested. This experience has confirmed the belief that it does not pay to

test the units on the erecting floor as the few leaks that develop on the hydrostatic tests can then be touched up without much trouble. Others considered the floor test desirable, however, for the sake of safety and to detect leaks in the back end of the units, which, should they develop under hydrostatic tests, might make necessary the removal of several units in order to get at the defective one.

Attention was also given to the application of the units in the superheater flues, some members considering improper application as the greatest source of leaky joints and, therefore, that attention to the fit of the unit in the tube and to the location of the header, which must be properly lined up with respect to the tube sheet, is of greater importance than attention to the joint itself. Trouble has also been caused by the accumulation of corrosion on the surfaces of the slots in the header, the crushing of which causes the joints to loosen up and leak.

REDUCING THE COST OF REPAIRS TO CARS AND LOCOMOTIVES

The committee dealt with this subject under 17 heads, each of which was outlined briefly with the purpose of stimulating discussion. An abstract of these subdivisions follows:

SUPERVISION

Careful, well trained supervision is essential. Supervisors should have, or acquire, executive ability—the gift of handling men properly; they should be interested in their men and like them. They should be big enough to get their heads and shoulders above the petty envy and jealousy that has a habit of creeping in. Supervisors who are favored with the opportunity to get a schooling in different departments or experience in different shops are indeed fortunate, and can and do return the favor to the company they are working for.

ORGANIZATION OF SUPERVISORS AND SHOP FORCES

In order to have an efficient, energetic and interested shop organization it is necessary to have the co-operation of all members of the staff. To increase this spirit it is advisable to have weekly shop staff meetings at which the welfare of the shop is discussed. At these meetings the shop superintendent or general foreman can get in personal touch with his organization and get a general idea of the condition of each department by the report that each department foreman turns in. This enables him to make any changes which he might deem necessary to further the production in his shop.

At these meetings, too, subjects may be brought up for general discussion, such as general shop conditions or methods to be adopted to shorten the time of machine or erecting floor operations, which tend to decrease the cost of repairs.

ROUNDHOUSE REPAIRS

The first object should be to take care of the small repairs on locomotives, which will take only a short time and require a small amount of material before they cause damage which will require more costly repairs. Roundhouse work properly looked after keeps locomotives out of the back shop a much longer time.

Roundhouse terminals should be provided with inspection pits for inspecting locomotives before passing over the ash pits in order to detect any parts that need repairs and have the information forwarded in advance to the roundhouse so advance preparation can be made for repairs.

BACK SHOP SCHEDULE

There must be a workable shop schedule or plan for getting the work out with the facilities contained in the shop. Since the piecemeal and bonus systems have been discarded it has been found that production has slowed up much to the dissatisfaction of all of us. It has, therefore, been necessary

to develop a shop scheduling system to take the place of the other systems.

MACHINERY AND FACILITIES

When it is possible to get new machines or appliances to replace old types they should be obtained immediately, but when this is not possible every loose end should be gathered in and the best made of the situation. There is more money wasted in making repairs to locomotives on account of the use of old and obsolete machinery than there is from any other cause. This is also true on mill work in the car department.

During the past few years locomotives have been growing in size and weight very rapidly; but in many cases the repair shops have not kept pace with them, and the result is high costs of repairs.

There is also another means by which the cost of repairs may be materially reduced and that is by the introduction on the machine floor of jigs, chucks, dies, box tools for brass work, pneumatic clamps, gang tools, milling cutters, templates and expanding mandrels, all of which reduce the cost of machine operations. On the erecting floors, power-driven valve setting rollers, motor-driven valve bushing pulling bars, rings for grinding cylinder faces and cylinder heads with air motor attachment, motor-driven flue cutters and flue rollers and chucks for grinding steam pipe rings and superheater units with motors have been found to greatly reduce the costs of repairs.

ROUTING AND LOCATION OF FACILITIES

All work going through shops should be properly routed, thereby doing away with unnecessary handling, which costs money. For example, all side rod work should be confined to one portion of the shop with rod rack, drill press, power press and lathe in close proximity to one another so that there will be no lost time between the several operations on the different machines. The driving box gang should have the power press, brass crucible for pouring hub liners, planer, boring mill, lathe and shaper within a radius of 10 or 12 ft., as they are in so many shops, so that when a driving box enters that radius it does not get away from it until finished and ready for application.

MATERIAL

Sometimes very little attention is given to the handling of material. A high rated mechanic may sometimes be seen pushing a truck up from the stores department with a load of material on which he is about to perform some kind of work.

This task should be taken care of by a trucker or laborer, thereby saving the difference in the two men's wages while at the same time the mechanic may be used on production.

Every effort should be made to have material placed in well regulated store departments so that when men are sent for certain articles they do not waste time looking for it.

The material required at the shops should be carefully watched by the supervisory forces and ordered in ample time to save delay and avoid the necessity of having to rob material from one engine or car for repair parts to use on another engine or car. Supervisory forces should keep in close touch with the consumption of material and should see that new material is not used unnecessarily, and that all second-hand serviceable material is handled properly to get the greatest amount of service out of it.

A well organized and well equipped central reclaiming plant is a great money saver.

PROPER HANDLING OF LABOR

Every employee should be impressed with the necessity of reducing all unnecessary expenses. A great many men are inclined to be careless about the use of material, especially

when somebody else is buying it, and consequently, unless a strict check is kept, much of it is wasted.

To get the men thinking along the right line some roads have arranged to have efficiency meetings in the offices of the master mechanic, between representatives of the shop crafts and the members of the staff about once each month, at which the subjects of shop repairs, use of material and the elimination of waste is discussed. These men take part in the discussion and advance many ideas from the employees' viewpoint which save time and material. Then once in eight or ten weeks a mass meeting is called in the shop 30 minutes before quitting time at which some member of the staff speaks, followed by a representative of the employees, who bring before the men the necessity for conserving material and thereby causing reduction in the cost of repairs.

A spirit of hearty co-operation should be cultivated between the engine crews, road foremen, and shop forces in order to get the help of the engine crews in carefully handling and looking after the engines on the road and making their work reports as explicit as possible.

WORKMANSHIP

Another manner in which the shop organization can keep the cost of repairs down is to insist upon each man doing his work thoroughly, instead of accepting slighted work, which is sometimes done because the engine is wanted in a hurry. This is a very expensive measure because it will not be very long before the job will have to be done over again, at the same expense if not more.

When cars and engines are shopped for general repairs, all parts should be carefully inspected and necessary repairs should be carefully and properly made. They should leave the shop in first-class condition, to render satisfactory service without it being necessary to expend much on them for running repairs. Running repairs are more expensive than back shop repairs because facilities are lacking. Furthermore, the service of the engine is lost while such repairs are being made.

Close care should be given to the proper mounting of car and tender wheels on axles to see that they are properly centered and the wheel gage fits properly at least at three equally distant points on the circumference, and that wheels of same tape sizes are paired. This will tend to reduce flange wear and hot boxes.

WELDING PROCESSES

A great saving in material is effected by the use of the electric welding process. Locomotive parts which formerly had to be scrapped on account of wear, such as guide bars, brake beam ends, brake hanger pins, radius bar ends, fork ends of eccentric rods which have become too wide for the link, driving boxes which have been worn down on the shoe and wedge faces, are now built up by the use of the electric arc and made almost as good as new. The oxy-acetylene torch, in the boiler department especially, is being used quite extensively for the welding in of flues, flue sheets, side sheets and patches, thereby reducing the cost over the old method of applying them with rivets. The use of the cutting torch must not be lost sight of. There is no department which can get more results from it than the locomotive department.

LUBRICATION

The lubrication of the end play on driving, engine truck and trailer boxes, and shoes and wedges with graphite grease prevents the cutting of these faces and increases mileage.

Care should be used to see that the lubricating devices are maintained in good condition and that sufficient amount of lubricating oils are furnished to meet the requirements. Under the present conditions the proper lubrication of cars and engines depends to a large extent on the shop forces.

The supervisory officers should realize this and provide necessary facilities for properly lubricating and looking after the parts in the shops that are not ordinarily given the required attention on the road.

A trained force of men should be maintained to look after the proper packing and lubrication of journal bearings and this work should be followed up by the supervisory forces to insure that it is being handled properly at all times.

DESIGN

Great care should be given to the design of parts to see that they are of sufficient strength and of proper quality to meet the requirements of the service without failing; also to see that the parts on cars, especially, are so designed that they may be easily removed for repairs.

REINFORCING CARS

Draft timbers and gears on wooden cars are the source of high cost of maintenance. The substitution of steel center sills, to which the draft gear is attached, will almost entirely eliminate the maintenance of draft timbers and draft rigging, as it gives a substantial attachment to pull the train and also gives a buffing member which will prevent buckling of cars and, in box cars, the breaking of side plates over side doors.

This feature in present-day heavy trains will more than offset any additional cost of repairs to cars and will have them on the repair track less frequently. Another feature of importance is taking care of the breaking out of ends of box cars.

This can be done by substitution of pressed steel ends, of which there are several kinds on the market, and reinforcing the ends with structural shapes which can be anchored to the side framing, floor framing or roof framing.

INSPECTION

A system of careful inspection should be enforced to detect any defects which may develop that would result in failure or rapid deterioration of parts if not located and given prompt attention.

CLEANLINESS

Engines should be kept clean and of good appearance as both enginemen and shop forces will take more interest in the engines if they are kept clean. This should be followed up by the supervisors and necessary facilities provided to handle the work economically.

Shops and premises should be kept clean and all refuse and material picked up. This raises the morale of the men.

SHORT TRACKS IN CAR REPAIR SHOPS

It is necessary to have short tracks of 10 or 12 cars capacity, and many of them, in order to get bad order cars spotted with regard to the work to be done on them. Short tracks will also aid in more frequent pulling of the bad order tracks and not hold up a large number of cars as is done on long repair tracks. The repair forces can be better supervised with short tracks and material is more easily handled.

CLASSIFICATION OF BAD ORDER CARS

Bad order cars should be classified as to light, heavy, general repairs and steel work or other special work before they are set on the repair track. This method increases the output, allows the work to be specialized and reduces the cost of handling material.

The report was signed by C. F. Baumann (C. & N. W.), chairman, C. W. Adams (M. C.), H. T. Cromwell (B. & O.), and F. L. Wysong (N. & W.).

Discussion

As a means of broadening the experience of supervisors, the discussion indicated that many railroads have adopted

the policy of sending groups of their foremen from time to time to visit the principal shops of other railroads. Where this practice has been followed the opinions expressed in every case indicated that the return to the company justified the practice. The value of reading suitable mechanical journals was also mentioned as a means of education which should not be neglected.

The opinion was also expressed that a real foreman requires qualifications which he possesses before he becomes a mechanic. In selecting foremen those men who have demonstrated qualifications of leadership should be tried out as acting foremen in advance of their selection to fill permanent positions.

The discussion indicated that shop scheduling is rapidly coming into general use. The systems described by those taking part in the discussion varied considerably in the details. Most of them, however, depended on periodical conferences of the shop foremen as a means of fixing the outgoing dates which, once established, are followed up consistently by means of schedule boards and daily reports.

The need of close supervision of speeds, feed and depth of cuts on machine tool work was brought out as particularly important at this time in efforts to secure adequate output. Many of the men on machines now seem to have little idea as to the capacity of high speed steel cutters and show little ability to figure out correct speeds and feeds. The tendency, therefore is to take more cuts than are necessary and operate at speeds which waste time. The discussion on workmanship dwelt largely with the importance of eliminating all unnecessary finishing of parts. Since the abolishment of premium and piece-work systems, where these were formerly in force, there has been a tendency for the men to do unnecessary work. In some cases this has been remedied by taking the matter up through the shop committees and impressing on them the need to avoid every possible waste of time.

During the discussion on the welding processes, Professor A. S. Kinsey, Stevens Institute of Technology, addressed the association as a representative of the Welding Conference Committee of the American Welding Society. Professor Kinsey dwelt on the importance of foremen having a more thorough knowledge of the essentials of good fusion welding. He referred to the fact that the Boiler Code Committee of the American Society of Mechanical Engineers will probably give a rating to fusion welds in boiler work and that the rating to be given will depend upon the kind of work that is being turned out. The foreman should know what kind of welds he is getting. Professor Kinsey referred particularly to the National Agreement as a hindrance to the full development of the possibility of fusion welding in railroad shops, since it places the welding jobs open to the senior craftsmen in the various departments, who may not be welders at all.

In discussing the sections of the paper dealing with car maintenance the present practice of maintenance, which goes on patching up the cars while giving no systematic attention to the draft gears, was condemned. It was stated that the same need exists for periodical inspection and repair of draft gears as has led to the present methods of air brake maintenance, and journal boxes. It was pointed out that such a policy adopted with respect to draft gears would soon demonstrate what gears are most economical. The value of the short repair tracks of 10 to 14 cars capacity was endorsed by the car men present.

Other Addresses

T. H. Goodnow, superintendent car department, Chicago & North Western, addressed the association on the problems of the car department. At the outset he called attention to the changed conditions surrounding the relations of foremen to their men, which must now be on the basis of a close

personal contact. These conditions the older men find hard to meet but the younger foremen should have no difficulty in conforming to them. Contrasting conditions in the car department to those in the locomotive department, Mr. Goodnow said that the greater part of the money spent by the car department is for work on outside repair tracks where the need for supervision is greater than in connection with any other railroad activities. Under the piece work system the men constantly kept after the foremen to see that they were furnished material. Since the piece work system has been abolished, however, conditions are reversed; the foremen must now closely watch the men to see that they are not idle because of lack of material at hand.

Mr. Goodnow called attention to the fact that the retirement policies of the railroads had to be abandoned a few years ago, thus continuing in service many old cars of light construction. Cars now cost not less than three times what they did in 1916, but in adopting a re-enforcement program it must not be overlooked that the same conditions prevail with respect to the material required to make the re-enforcements. It must also be taken into consideration that the small capacity car is a low earning unit. Where wood cars of 80,000 lb. capacity can be re-enforced at a cost of about \$300 to \$500 a good earning unit is provided.

E. W. Pratt, formerly assistant superintendent motive power of the Chicago & North Western also gave a short talk before the convention in which he commented on the fact that most of the subjects for discussion on the program dealt with apparatus or were of a technical nature, while every general foreman in the association probably owed his best job to his ability to handle men. Mr. Pratt suggested that the association might profitably give more attention to subjects dealing with the handling of labor and shop organization.

Election of Officers

The following officers were elected for the ensuing year: President, J. B. Wright (Hocking Valley); vice-president, G. H. Logan (C. & N. W.); second vice-president, H. E. Warner (N. Y. C.); third vice-president, T. J. Mullin (L. E. & W.); fourth vice-president, C. A. Barnes (Belt Railway of Chicago), and secretary-treasurer, William Hall (C. & N. W.). M. H. Westbrooke (Grand Trunk Western) and D. W. Adams (M. C.) were elected to fill vacancies on the executive committee.

CARS MUST BE EQUIPPED WITH SAFETY APPLIANCES

The Interstate Commerce Commission has denied the application of the American Railroad Association on behalf of various railroad companies for a further extension of time within which to make their freight-train cars conform to certain of the standards of equipment prescribed by the commission pursuant to the provisions and requirements of the safety appliance acts.

In accordance with the authority conferred by the provisions of the act the commission had granted successive extensions of the period within which common carriers should comply with the requirements of its order of March 13, 1911, with respect to the equipment of cars actually in service on July 1, 1911, as follows: On March 13, 1911, an extension from July 1, 1911, to July 1, 1916; on November 2, 1915, a further extension to July 1, 1917; on April 12, 1917, a further extension to March 1, 1918; on February 1, 1918, a further extension to September 1, 1919; and on August 29, 1919, a further extension to March 1, 1920, making one continuous period of eight years and eight months from July 1, 1911, to March 1, 1920. Passenger-train cars and locomotives were equipped in conformity with the standards within the periods prescribed by the first extension order.

The second, third, fourth and fifth extension orders pertained to paragraphs b, c, e, and f of the original extension order, paragraphs a, d, and g being so worded as to require no further action.

"The record shows," the commission says in its decision, "that on February 1, 1920, there were 2,319,380 freight cars owned by the carriers represented at the hearing, and that 60,170 of these, or 2.6 per cent of the total owned, were not equipped in conformity with the standards prescribed by the order of March 13, 1911. It is estimated that 3,000 were equipped during the month of February, and that 12,021, or 20 per cent, were special service cars or others cars which do not leave the owning line.

"No reason was given why these 12,021 special service cars have not been equipped in conformity with the law or why they cannot immediately be so equipped. This leaves 45,149 other cars to be equipped. Sixty per cent of them need minor repairs only, but more or less difficulty is involved in equipping the remaining 18,060. Of these, 9,272 have less than ten inches end-ladder clearance. If a special drawbar is used, the larger percentage of the 9,272 cars can be made to conform to the requirements. The number of bad-order cars on the lines of these carriers is about 138,000, or approximately 6.5 per cent of the total number owned. The percentage of the number of bad-order cars has fluctuated during the last two or three years between a little over 5 and about 10 per cent. Most, if not all, of these non-equipped cars have been through the shops in the last 9 or 10 years. A witness for the carriers stated that he did not know that any car could stay out of the shop that long.

"It can not be maintained that the failure to have these cars equipped in conformity with the standards is due to any unforeseen contingency. The requirement for the standardization of safety-appliance equipment is of long standing, and attention has been directed to this requirement from time to time in previous hearings in this matter as well as in the several extension orders; at the hearing in August, 1919, the situation was discussed and the understanding was had that no further extension would be necessary, asked, or granted. The arguments that shortage of material and absence of the cars from the lines of the owning carriers have delayed the required standardization are not convincing with respect to those cars which require only minor repairs, inasmuch as safety appliances are of standard dimensions and an order issued by the Railroad Administration June 30, 1919, required each carrier to equip all cars on its line not already standardized, regardless of ownership. We have seen that it will be more or less difficult to make 18,060 cars conform to the standards. But if these 18,060 cars are added to the number of bad-order cars, shown by the record to exist on the lines of the carriers, the percentage of bad-order cars will be increased less than 1 per cent, or from 6.5 to 7.3 per cent; and if the entire 60,000 cars not equipped according to standard were added to the number of bad-order cars the percentage of such cars would be increased to 9.2 per cent, a figure less than the maximum, which, according to the record, has existed during the past two or three years.

"It is noted that all of the unstandardized cars referred to herein were in service July 1, 1911, and all of them are consequently nine or more years old. No doubt many of these cars have practically outlived their usefulness and nearly reached the age of retirement. Cars of that age, if they have not heretofore been shopped for extensive repair work, must shortly go through the shops, at which time the safety-appliance equipment can and must be made to conform to the standards.

"Upon consideration of all the facts of record we are of opinion and find that good cause has not been shown for any further extension of the period of compliance and that serious burden or hardship will not be imposed upon the carriers or upon the public by denying the application."

PAINTERS HOLD FIFTIETH ANNIVERSARY CONVENTION

Equipment Painting Division of the American Railroad Association Holds Convention in Boston

THE convention which met in Boston on September 14 was an event of unusual interest and importance to the members of the Equipment Painting Division of Section III, Mechanical, of the American Railroad Association. It is the first convention of this association as a division of the American Railroad, as within the past year the Master Painters became a unit of the American Railroad Association. The Master Car and Locomotive Painters' Association was organized in the city of Boston in 1870 and in the opening exercises of the fiftieth convention, the association was addressed by Mr. Warner Bailey of the Boston & Maine Railroad, who took an active part in the organization of the association and who is now the only living charter member.

Warner Bailey's Address

The following is taken from Mr. Bailey's remarks in regard to the origin of the Association and his splendid conception of its purpose in promoting the welfare of the American rail-ways:

"In the summer of 1870, Hill of the Portland & Kennebec Railroad; Cox of the Eastern Railroad; Scott of the Boston & Lowell; Lunt of the Fitchburg; Platt of the Old Colony; Ford of the Boston & Worcester; and Bailey of Boston & Maine, met together by previous arrangement and talked

over the question of forming this association. I was chosen for the task of addressing a circular letter to be sent to foremen painters and the only guide I had was 'Poor's Railroad Manual.' In most cases only the president's and superintendent's names were there

given and the call was sent to them with a request that it be handed to their foreman painter. On November 6, 1870, when the meeting was called, sixteen members responded. Hill of Augusta was made chairman of the meeting. After appointing a committee to draw up a constitution and by-laws and selecting a few subjects to be discussed at our next meeting we adjourned to meet in New York City the following year.

"For many years we, as an association, struggled along without much increase in numbers, and little encouragement from any source, until we added to our numbers by taking in foremen locomotive painters and foremen of car manufacturing shops, both steam and street car. Also Canada was admitted with this addition, and today we number about three hundred members.

"We have always kept in mind the object of this association, as stated in the circular letter issued for the first meeting; and that was to perfect ourselves in our trade that we might be of more benefit to corporations employing us. I think we have always kept this object in view; and that

Photo by Kimball Stuaue, Concord, N. H.

Warner Bailey

our yearly reports prove this.

"Among the notable members that have belonged to the association, who in times past have added greatly to our information, is James A. Gohen. Quest, with his technical papers, and Miller, with his practical papers, have added greatly to our knowledge, while Copp, Butts and a score of others of equal note have helped to make this association what it is today.

"What is the prospect for our association? I can safely say that this association will keep on indefinitely in its career of usefulness if the same principles actuate you as moved the founders of it; and this was to perfect themselves in their trade. If you know it all, then there is nothing for you to do but quit these assemblies, unless you come together wholly for a good time; and in this you might well consider whether or not it might better be spent in other ways and places. We do not know it all yet. New kinds of equipment and new ways of doing things are constantly developing and you will always want to keep these meetings going to discuss them.

"A year ago you dropped your name and entered the American Railroad Association as a unit in that great and useful organization. Let us hope this will widen the scope of your usefulness, as doubtless it will."

Chairman Gibbons' Address

In his opening address, Chairman J. W. Gibbons of the Atchison, Topeka & Santa Fe spoke of painting as one of

J. W. Gibbons
Chairman

E. L. Younger
Vice Chairman

V. R. Hawthorne
Secretary

the oldest arts, deriving its origin and receiving impetus in the desire of the human race to beautify its surroundings. Thus, in the beginning ornamentation was the dominant feature that impelled or inspired the craftsman. As the art progressed and developed, the thought of the painter was to preserve his work for the pleasure and inspiration of future generations. In order to accomplish this purpose, he studied the vehicle that carried and held his pigments together and assisted him to make the correct blend and shade of color, as well as protect the finished product from the ravages of time and weather. As the use of wood became more general, the quality of oils and gums became more important and were not only used to preserve the wood but to beautify it by imparting to it variegated colors and a lasting polish.

To solve these problems which have developed with the advent of the railways, Mr. Gibbons said that the painters realized the necessity of getting together for the discussion of application and formulating combinations of vehicles and pigments best adapted to perform the service required. With this object in view, The International Association of Master Car and Locomotive Painters was organized fifty years ago. When it is realized that at that time it required from six to ten weeks to paint a railway coach with no better or durable surface than we now secure in fifteen to eighteen days, it proves that these painters must have been inspired with the

same independence of thought and action that inspired the patriots of American colonies to discard the traditions and prejudices of the past and build for the present and the future.

Chairman Gibbons stated that the paint manufacturers have derived more benefit from the work of this association than the railroads, because the manufacturer's welfare and success in business depended upon his keeping in touch with the most advanced thought of the day pertaining to paint, while on the other hand railroad mechanical officials have frequently and openly declared that the paint questions was the least of their troubles and are wasting thousands of dollars every day by the purchase and application of poor paint.

In concluding his address, Mr. Gibbons said that no section or department is undergoing such rapid changes as that of paint, its manufacture and application. The high price of raw materials, heretofore recognized as essentials, has offered a great temptation to substitute inferior materials into the finished product and it devolves upon the association to point out how far we can go with safety and economy along this line.

Business of the Association

The chairman announced that during the year the association had received a number of new members and that at the present time the membership of the Equipment Painting

Division of Section III-Mechanical, of the American Railroad Association was in excess of 500.

The committee on direction, as its name indicates, directs the affairs of the association between conventions and was requested by the A. R. A. to elect a committee of three to act with a similar committee from the purchasing, stores and chemical sections to prepare specifications and arrange tests for paints and varnishes. Mr. John Gearheart, Mr. John D. Wright and the chairman were elected to this committee. The committee at its last meeting passed a resolution requesting the committee on nomination to select the 1st and 2nd vice-chairman with the idea of their promotion in rotation and that the 2nd vice-chairman be selected from the board of directors and the selection of new members of the board from members who on the committees and on the floor have demonstrated their ability in this work. The division was requested to appoint a committee to co-operate with the Committee on Car Repair Shop Layouts of Section III-Mechanical, and the Committee on Shops and Terminals of Section II-Engineering, for the purpose of arriving at standards which would assist in the design for future paint shop construction. The new Committee on Direction was instructed to select a committee for this purpose.

The chairman expressed the thanks of the association for the frequent advice and courtesies extended by the officers of

the American Railroad Association and particularly for the very able assistance rendered by Mr. Hawthorne, secretary of mechanical section and this division.

The convention adjourned after electing the following officers for the ensuing year: B. L. Younger, Missouri Pacific, chairman; J. G. Keil, N. Y. C., first vice-chairman, and J. R. Ayers, Canadian Pacific, second vice-chairman.

THE ECONOMICAL PAINTING OF PASSENGER TRAIN STEEL CARS

BY G. H. HAMMOND
M. St. P. and S. S. M.

On a sand blasted car there is generally applied a coat of steel primer which is followed by several coats of steel surfacer. After the surfacer has been made smooth, two coats of body color are applied followed by the necessary lettering, and the whole protected by two or three coats of body varnish.

The steel primer comes to us all ready to apply, and is highly recommended for the first coat on steel. The material is a thin varnish-like substance, colored or clear according to its source of manufacture, and is *not* recommended as a protection to steel when used alone. It must itself be protected by other paints.

What is surfacer, and why is it applied to steel cars? It is simply another form of putty, and the only reason why it is used is to obtain a smoother and more level surface. For this reason its composition must of necessity be inelastic and chalky. If exposed to the weather alone it would fail completely.

After the surfacing coats have been worked into a satisfactory condition, the color coats are applied to it. These two color coats are made up of body color ground in Japan and thinned to a working consistency by the mixing in of turpentine or turpentine substitute. The body color coatings if exposed alone to the weather would soon disappear and be of no value in protecting steel from rust.

So far in the process of painting a steel car three classes of materials have been used—the priming coat, the surfacing coats and the color coats, and none of these coatings, alone or together, would protect steel from rusting more than a short time. What then is the protection from rust? Varnish must be the answer; two or three coats are applied on top of all the previous unstable coatings. It must not only ward off the weather, but must also hold the previous coatings to their place.

This method of painting steel cars is simply applying to steel practices and material found adaptable to wood, and the results are not satisfactory. Cracking of the varnish, peeling, and rust spots appear all too soon. These coatings which are put on so carefully and part of which are rubbed off with equal care, and which we know to be so poorly adapted to the protection of steel, must be mainly responsible for the unsatisfactory results. This being the case why not eliminate such material entirely from a place on the bodies of our steel passenger cars, and not only save the cost of such material but the big item of labor required to apply it, and use only such material as we know to be elastic and durable?

One coat of body color and three coats of varnish is all that a steel passenger car body really needs and it will remain bright and lustrous much longer than those cars loaded with many coats. The body color should be furnished in paste form, ground in equal parts of raw linseed oil and gold size japan. To prepare it for one coat work on sand blasted steel or repainted cars, reduce it with raw linseed oil, and nothing else, to a consistency that will cover with one coat, apply with a bristle brush and smooth with a hair brush. The next day all necessary lettering is done. All places lettered with leaf should be well pounced with whiting before sizing to prevent leaf from sticking to body color, and be washed off when the lettering is dry. The following

day the first coat of varnish is applied, followed by two more, forty-eight hours apart, until three coats are applied, at which time the car body is finished.

You will notice that no other work is done except these four coats and the necessary lettering, and you will perhaps wonder how a steel car finished in this manner would look. It will have all the brilliance of color and all the varnish luster that could be desired, and as for the smoothness of finish, unless a very close inspection is made, no difference in finish would be noticed. Cars constructed of plates riveted together will not show a level surface; regardless of what the painter may attempt to do to make it so, each plate will show bulges or depressions which are impossible to eliminate and barring deep pits in the surface of the steel, any surfacer or putty applied is so much material and labor wasted. Steel plates containing pits should never be accepted if placed in a position to show on the outside of a steel passenger car. Cars constructed of thin steel in imitation of wood sheathing are perfectly smooth and level before being sent to the paint shop, therefore any surfacer or putty applied would be superfluous.

When it is necessary to repaint, the old varnish is sand papered, a coat of oil color is applied, followed by three coats of varnish. After several shoppings such cars become just as smooth at close inspection as a surfaced car.

Discussion

J. D. Wright: The Association cannot go on record as recommending one coat of body color and three coats of the best outside wearing body varnish as a standard method of finishing the exterior of passenger cars. While the method may be feasible with an oxide of iron color, it may not be feasible with a color which is composed of ochre or chrome yellow and carbon black and a very small percentage of red, which are the pigments used in the manufacture of what is known as standard Pullman body color.

J. B. Ayers (C. P.): Dr. Johnson, engineer of tests for the Pullman Company, told me up until six or eight years ago considerable cold rolled steel was used in the construction of passenger equipment. That steel is very similar to the present steel extensively used by the automobile body builders. That steel is smooth and does not contain flash scale or pits. I believe cars on the Soo Line are fortunate enough to have steel of that character.

Mr. Butts: As an experiment I took two Pullman coaches, and treated them exactly the same, the same day, with the same kind of material. One was put on the run north to Winnipeg and back, and kept on that run for twelve months. The other car, painted exactly the same, went on the Portland, Oregon, run and was kept there for twelve months. At the end of the twelve months the one on the Winnipeg run was in fine condition, needed nothing but touching up the varnish. On the one on the Portland division, the varnish was so badly decomposed that it had allowed the surfacer to be attacked by the alkali, and we had to burn the car off. You cannot adopt a standard for all parts of the United States and make it a success for painting passenger equipment.

REPORT OF COMMITTEE ON MAINTENANCE AND CARE OF PAINT AND VARNISH AT TERMINALS

The committee would first urge that the attention of passenger equipment at terminals should be under the supervision of a man who is familiar with the nature of paint and varnish, so that the cleaning done at terminals would not be done with materials and in such a manner as to injure or hasten the termination of durability to varnish and paint; that cars after coming from the shop freshly painted should not be cleaned with the use of a solution of any kind until such time as the condition of the car makes this absolutely

necessary. In maintaining and caring for the paint and varnish of such cars at terminals, a dry wiping with waste after each trip is all that is necessary. When the condition of the car becomes such that it is necessary to use a cleaning solution, an oil emulsion that is made neutral and has a tendency to feed the varnish should be used, care to be taken that it is wiped absolutely dry before car is again put into service, as car is bound to gather a certain amount of dust and dirt immediately after this treatment. After car has been cleaned in this manner, it can again be taken care of for some time by simply dry wiping after each trip.

The committee is unanimous in recommending that soap and water should never be used in the open air at terminals for cleaning the exterior of passenger cars, unless immediately rinsed off with clean water and dried thoroughly with a chamois, as the sun will dry soap and water on the surface of car very rapidly, thus injuring the varnish. A practical demonstration of this may be made by washing your automobile with soap and water and rinsing with clear water without drying thoroughly with a chamois.

Painted floors of cars should not be mopped with a strong solution of any kind, but when mopping is done use only a weak solution of oil soap with a proper disinfectant, which will not injure floors. If this practice is followed, floors will not require repainting as often as otherwise would be the case.

It is very important that roofs of cars be inspected frequently at terminals, and if necessary repainted without waiting until the car is shopped for general repairs or repainting. If this practice is followed, it will tend to preserve the roofs so that when car is finally shopped for general repairs and repainting the roofs will be in good condition and will not need extensive repairs.

The interior of passenger cars should have the varnish or enamel wiped occasionally with cloth dampened with neutral interior renovating oil, which will brighten and renew the varnish or enamel greatly and improve the appearance of the interior and will also assist in preserving the varnish or enamel.

The committee does not approve of the use of washing or scrubbing machines on the tanks or cabs of locomotives, but sees no objection to their use in cleaning the frame, wheels, etc. It has been the experience of the members of the committee that the use of these machine on varnished surfaces is very injurious to the varnish.

Cleaning Enamel and Varnish Surfaces

In order to obtain the best service from cars painted with enamel without varnish, the car should be primed and surfaced in the usual way and given two coats of oil varnish enamel, which dries very slowly. It has been the experience of the committee that the clear varnish enamel does not give the same surface as the oil varnish enamel. The use of oil varnish enamel, which dries very slowly, necessitates allowing more time between applying coats, thus delaying the return of car to revenue service.

Gold leaf lettering cannot be used on such enamel, as the enamel being of a finishing coating the leaf adheres around the edges, therefore the lettering must be of an imitation of gold, that is a gold color paint. A car finished in this manner does not have the same high lustre nor give the same satisfaction in appearance as the car painted in the usual manner and given the usual coatings of clear finishing varnish, although, considering the first cost, the car can be painted with enamel for a few dollars less than with varnish. In cleaning the cars at terminals, however, the car with the varnished surface can be cleaned more easily and present a much better appearance and with less cost, because on the varnish finished surface the dirt has not formed a part of the painted surface. In the case of the enamel finished car, however, it is much more difficult to clean and does not

present as near a satisfactory appearance after cleaning, as the dirt and dust adhere to the painted surface.

Another very important point and worthy of consideration is the fact that the enamel surface will not bear as frequent cleaning as the surface finished with varnish. When an enameled car is scrubbed, it is generally found necessary to enamel again with two coats and reletter car, while the varnished car can be scrubbed and either touched up and varnished or cut in and varnished, according to color of body, with less cost than enameling and relettering.

It was the conclusion of your committee that, giving due consideration to appearance and cost, it is preferable for the purpose of cleaning to have passenger equipment finished with varnish.

The report is signed by: A. H. Phillips, N. Y. O. & W.; J. W. Houser, C. V.; Jas Gratton, B. R. & P.; E. A. Witte, T. R. R. Asso., St. Louis; J. W. Quarles, C. & O.

REPORT OF COMMITTEE ON STANDARDS

The committee recommends the universal adoption of the standard of the former Master Car Builders' Association for uniform stenciling and lettering of freight equipment and suggests that every effort should be made to put this standard of lettering in practice. The universal use of this standard would eliminate the making of innumerable stencils and a great amount of hand work, and should bring about considerable reduction in expense.

The report states that the general adoption of this standard method of lettering freight car equipment would solve one of the perplexing and annoying problems which confront the railroad men entrusted with taking of car records. It is believed that the standard method of numbering and stenciling recommended by the former Master Car Builders' Association, and now a standard of the Mechanical Section of the American Railroad Association, would eliminate such errors and save much annoyance.

Exhibit "A" shows the cost of making stencils required for lettering freight car equipment of the different railroad lines. These costs are based on old figures and at rates of wages which have increased considerably since that time, so, in all probability, they would be from 30 to 40 per cent higher at the present time.

On repair yard tracks it is estimated that 60 per cent of all repairing is to foreign car equipment, most of which requires the replacement of more or less stenciling in order to maintain the identity of the cars. This requires the repairing line to carry in stock stencils of nearly every type and size of

letter and number. Some of these stencils are used frequently and others not so often. Nevertheless, it is necessary to keep this stock of stencils, for most repairs are of the hurry-up kind which excludes off-hand lettering.

The committee recommends that trade marks or badges should be part of the expense for each individual car owner to assume if they wish same replaced on their equipment. The stencils for these trade marks are very expensive, as the attached exhibit "B" will show, and the committee would recommend their discontinuance, as the only reason for their use seems to be as a means of advertisement. Most trade marks require backgrounds other than the standard colors used for painting equipment, and thus require an extra application of paint. This necessarily delays the completion of the car and at the same time adds to the cost of stenciling.

As the committee believes that economy is the watchword of the railroads today, the elimination of these shields and trade marks is one practical way to reduce expense.

Recommended Practice for Painting Freight Car Equipment

As the protection is an absolute necessity, the committee recommends that the new steel car should have a coat of red lead applied to all lapped parts before assembling. Upon completion of construction the exterior should be thoroughly cleaned and prepared by sand blasting. A priming or first coat of paint should immediately be applied both inside and outside. This should be a linseed oil mixture requiring twenty-four hours to dry.

The carbon blacks are the best wearing and the most appropriate coating for this class of equipment. After this, and perhaps but little less in wearing quality, are the oxide of iron pigments. The preparation of this coat, as to pigment and vehicle, should be such as to insure an ideal binding and elastic film. A second coat with about one-third more oil should be applied. Great care should be taken to see that every part of the car is covered. Both coats can be effectively applied by spraying. For patch work or repainting the same method should be applied as in new work, that is, all scale and rust removed and two coats of paint applied.

The recommendation of the committee is to use one coat of primer made from red lead and oil, followed by a coat of carbon black in oil. This has not been generally carried out because of the first coat of raw material, red lead being high in price. As an alternative, the committee would suggest the use of carbon black in oil or graphite, or preferably iron oxide in oil.

Carbon paints are not safe to use as contact coats on metal as they are good conductors of electricity and act as rust stimulants. However, they make good top coats. Graphite paints are not good inhibitors of rust because of the ease with which they conduct electricity. It has no action on oils except to retard drying. It is a greasy pigment and slides under the brush and the particles tend to segregate and should be mixed with a heavier pigment to give it tooth. Asphaltum and coal tar black has practically no value as a protective coating. It generally contains no oil at all, has very little toughness, and its acidity tends to promote action of rust.

No part of railroad equipment is more essential than the air brakes, and one of the most frequent causes for defective brakes noted is leaky trainlines caused from rusted pipes becoming weakened and breaking at joints. Air brake lines have been frequently observed in so rusted a condition that whole sections of the piping had to be removed on account of rust having caused the sections to become porous. For this reason it would seem most essential that they should be protected with paint and continually watched. A well painted air brake line will render inspection of this part of the equipment easy and will also lead to detection of flaws and breaks which can be reported to the proper officer.

Recommended Facilities for Freight Car Painting

The most convenient place to paint freight car equipment, weather conditions being favorable, is on the outside of shops located as conveniently as is possible to the place where the repairing is done. The longitudinal tracks are best adapted for this work and should be properly equipped with air lines, with plenty of space between tracks. A stationary scaffold of simple construction is very convenient and a great time saver. Care should be taken that such tracks used for painting should be kept exclusively for painting purposes, for the reason that the tracks must be kept clean of all rubbish or obstruction in order to facilitate the painting work and thus insure quick return of cars to revenue earning service.

The best system of painting freight equipment and in standardizing results obtained by such painting is to do the work in properly constructed shops. This will allow a uniform amount of work under varying weather conditions. It will also permit planning the work and directing it properly, rather than having cars located all over the yards and men working without adequate protection or supervision. Where spraying machines are used in closed shops, provision should be made for sufficient ventilation. There are times when freight cars can be satisfactorily and efficiently painted on the outside of shops, but during most of the year work in the North can only be properly done within four walls and under a roof. For this reason a shop for painting freight cars is both economical and efficient.

Recommended Frequency for Painting

It is becoming most essential because of lower production and higher cost of labor, material and new equipment, that greater care be taken in the inspection and painting of steel equipment on railroads. Attention should be given to inspection of freight cars at yards, and a repair or patching crew should be kept at principal junction points equipped with material necessary to fight rust. Steel freight cars should be brought into shop for repainting and repairing every three or four years.

Opinions vary very much with regard to the time a car should be brought in for general overhauling and repainting. If the initial preparation and painting has been properly done and cars not subjected to unfair usage, such as the hammering of sides for the purpose of dislodging, or the loading of hot slag or billets in cars, there is no reason why coal carrying cars should not give three years' service before reshoppping. The use of such cars for storage of coal during winter months is very injurious as the sulphur drippings from coal will very soon destroy the paint film and cause corrosion to the parts attacked. All steel box cars, if properly painted at the beginning, should give a longer term of service. However, the under portions such as channel irons, underframes, etc., must be continually watched and kept painted.

In view of the above, it is the opinion of the committee that the standard practice on railroads should include thorough overhauling of all steel freight cars at least once every five years and the painting of underframes at every opportunity offered.

The report is signed by: S. E. Breese, N. Y. C. (chair-

man); G. J. Lehman, C. & E. I.; F. E. Long, C. B. & Q.; W. A. Buchanon, D., L. & W.; C. A. Cook, Pennsylvania.

Resolution Adopted

Whereas a large proportion of freight equipment cars in service bear markings not conforming to the American Railroad Association recommended standards as shown on drawings 26, 26a and 27, thereby making necessary the use of an endless variety of sizes and types of letters and figures. And whereas, the condition greatly increases the cost of repairs to foreign line cars, due to the necessity of applying markings by hand, or the making of numerous stencils for temporary use; and whereas, the condition is frequently the cause of wrong numbers being recorded by transportation department employees, causing confusion and needless correspondence; be it therefore resolved, that this division recommends any action necessary to urge all railroads to follow a uniform practice and use markings as recommended by the American Railroad Association, also that a rule be adopted making it permissible to use such markings, disregarding the manner in which the cars were previously stenciled, and making all marks of an advertising character billable against the owners.

INDIVIDUAL PAPER ON ECONOMY TO BE EFFECTED BY PROPER PAINTING

BY B. E. MILLER
Delaware, Lackawanna & Western

In order that economy in the maintenance of equipment by painting may be effected in the fullest measure, cars and locomotives should be shopped and given the needed attention whenever their condition demands it. Again the management has to be reckoned with. Can locomotives in serviceable condition be spared for painting? No. Neither can cars, especially freight equipment, when there is an abundance of business and a shortage of rolling stock. The consequence is frequently disastrous. Witness the present condition of the average freight car throughout the country today. The cars of all railroads having been pooled during recent government control, little attention was given to the matter of painting. The result was soon apparent. Steel coal-carrying cars, many of which were in none too good condition when the government took hold, began to look disgraceful; rust, that arch enemy of steel, was making rapid progress. Some of the cars are in such bad shape as to make their cleaning up and conditioning for repainting practically impossible. In many cases, the last coat of paint, probably a poor article when applied, has disintegrated and washed off, leaving no protection to the surface and exposing double lines of lettering frequently, which, to say the least, is very annoying and proves the wisdom of applying a paint possessing durability, though it means perhaps a little additional time for drying or an extra coat of paint to insure wearing results. The present "run down at the heel" appearance of equipment might of course have been avoided had it not been for the war, scarcity of help, the peculiar conditions due to government control, etc. Had it been possible to give the cars *proper* painting when their condition made it advisable, many dollars might have been saved to the railroads, so far as the painting itself is concerned and deterioration avoided. Especially does this apply to steel equipment and steel portions of wooden cars.

True economy in the painting of railway equipment means to do the work promptly, once it has been determined that painting is necessary. This ought to be made plain even if there is no hope of influencing those who decide as to when cars can be spared from service for painting and when financial conditions will warrant the expenditures necessary to do the work.

Use only good serviceable materials. As a rule, it doesn't

pay to bother with anything else. The present high cost of labor and the difficulty of securing it, demand that money shall not be thrown away, partly at least, in the direction of applying paints and other materials which lack efficiency and durability. It requires no mathematician to figure out that, as a rule, the higher priced material proves itself to be the cheapest in the end. This has been said so often and evidently with so little effect, that we almost hesitate to repeat it.

Purchasing agents, unless strong pressure is brought to bear, are inclined to invite ruinous competition when placing orders for supplies. In the matter of paints, as with other materials, they are apt to purchase solely on price, unless they can be successfully convinced that, in some cases at least, it is rank folly to do so. Happy indeed ought the painter to be whose complaints, when made to the proper official, receive the attention they merit and eventually reach the person responsible for the placing of orders. His duty and aim is to save money. If he can be thoroughly convinced that paying more for material means in the end true economy, he will often be persuaded to buy the higher priced goods.

Discussion

J. W. Gibbons (A., T. & S. F.): Five years ago, in a shop within my knowledge twelve per cent of all the steel cabs coming through required new roofs, because of improper painting and care. After the officials' attention had been called to that condition, and a standard practice adopted, not only of painting, but of keeping them clean, each year from that time until this day there has been a gradual lessening of expense, until last year there was not a single full roof put on any of the locomotive cabs coming through that shop. Five years ago there were twenty-five sides put on steel cabs; last year there were three.

I have noticed our steel passenger cars, the deck side particularly, panel after panel corroded through. If these had been properly painted when they were constructed or when they were in the shop at the last period, all of that labor and material would have been saved to the railroad company. Our superiors oftentimes do not have the slightest idea of what could be saved by proper painting.

Very few of us can say that we are using the best material, and that has been particularly true in the last two or three years. Price has been the first consideration, but should be the last consideration. If the painter knows his business, his word should be accepted.

W. A. Buchanon (D., L. & W.): I have frequently had occasion to look over steel equipment, and just recently looked over some new steel equipment just from the factory that had been painted, and well painted as far as material went, over mill scale. It is the height of folly to attempt to paint over mill scale and expect it to stand. It should first be removed or you will throw away good material in painting steel cars.

W. O. Quest (P. & L. E.): The road I represent was one of the first to get steel car equipment. I remember reading an article by a mechanical engineer to the effect that a steel car would last thirty years on two paintings, the original and one painting afterwards. At that time I presume he failed to take into account how a steel car was to be abused around these mills, with hot slag and hot billets, and the other deleterious things that came afterwards. I recall reading another article in which another mechanical engineer claimed that in ten years they would be falling down on the lines, which also was a mistake.

Paint is necessary to keep steel cars to long life, the best paint you can buy and with the very best sort of application. The original painting must be considered. The original painting of steel car equipment should not be forced to the extent of two coats a day in order to get the equipment out. You have a great many cars, and it is difficult

to figure when you will get those cars in the shops. You say a car must come in every five years, but you don't know whether it will or not. But the thing to do is to paint every steel car.

REPORT OF COMMITTEE ON TESTS

The committee in its report has assigned each subject under consideration to an individual member of the committee. These individual papers have the approval of the entire committee and are presented herewith.

WHAT IS THE SO-CALLED FIXED PAINT OIL?

BY W. O. QUEST
Chairman, Pittsburgh & Lake Erie

Does the term fixed paint oil exclusively apply to the chemistry of paint making? Is this oil fixing confined to the proper fixing of commercial linseed oil, or does it mean that any kind or compounds of oils containing a partial or whole percentage of body weight lin-oxygen can be made through further admixture into heavy bodied substitutes that will answer the same purpose as the pure treated or properly fixed linseed oil. This question has caused much thought and study, owing to the fact that immense quantities of oils other than linseed are used today in paint making and consumption.

The writer is now offering something new along the line of oil fixing, which is an attempt at oxidizing non-oxidizing oils, with their after removal in film form for your tolerant inspection. These oils range from a locomotive cylinder oil down to the oil of goose grease. The idea of such a test was to ascertain if there was an available trick material that would oxidize or dry fix grease oils into films that could be removed—removed regardless of the apparent impracticability of the scheme. They may not mean anything, unless such tests would prove that there are oxidizing materials neutrally fit and strong enough to set up or turn a non-oxidizing oil into something like a fixed paint oil to a bodied film that can be removed, viewed and handled.

For your further information, will state that the same method and amounts of a specially made japan were used on all of the non-oxidizing oil films taken off, also that the drying time periods and results were fairly uniform. A fixed paint oil other than linseed should be so labeled, called by its right name; if not, the use of such spurious materials should not be encouraged in the railway paint shop.

COMPARATIVE VALUES OF TUNG NUT (CHINA WOOD) OIL \$2.00 VARNISHES vs. THE OLD STANDARD FOSSIL GUM, SUCH AS ZANZIBAR MANILLA OR KAURI

BY THEO. HIMBURG
D. & R. G.

The committee calls attention to the fact that many American varnish manufacturing concerns claim they have discovered a dependable substitute for the old time honored, high priced fossil gum, railway body varnish which has always rated in the railway paint shop as the only acceptable grade of protective wearing varnish.

The committee has done some experimenting with china wood oil for its own benefit. Some linseed oil was boiled at 550 deg. F. for several hours, and it boiled slowly and uniformly. When china wood oil was heated to this same temperature it changed in a very short time from a liquid to a semi-solid state, in which form it was disintegrated and sticky. It seems that when wood oil is thus heated and solidified it is useless, because it is insoluble in turpentine, naphtha, benzol, alcohol or any commercial thinner.

There is one thing which can control it, and that is rosin. If rosin be added just at the point when the oil is passing from the liquid to this useless state, it brings it back to the liquid form. Furthermore, this action can be repeated sev-

eral times and finally, when the mass is reduced with turpentine or other solvent, it soaks it up like a sponge. This phenomena is called false body by the varnish makers.

With exactly the same quantity of gum and oil they can, for example, make two varnishes of the same viscosity, but with one containing twice as much thinner as the other. It is obvious, though, one will have only half the true oil content of the other and proportionately less durability. To all physical appearances, such as body and dry, they are identical.

It is universally recognized that china wood oil fills a distinct need. It has unequalled waterproofing properties, but lacks the refinement and working of linseed oil. A proper combination of the two should give the ideal varnish.

A straight china wood oil varnish when allowed to stand open will first form jelly-like "gobs" and quickly skin over. Also, when it dries and is rubbed the film does not cut down cleanly like linseed oil, but it will be noticed particularly under a magnifying glass that it has a tendency to "rough."

Petroleum distillate has more cutting power than turpentine, that is to say, the addition of identical amounts of petroleum distillate and turpentine to the same quantity of a varnish will give a thinner body in the case of the one reduced with petroleum distillate. As there is no turpentine in these two-dollar varnishes, we therefore spread less of a wearing film on our work. Finally, the big saving must come in the gum, and it is apparent that they are rosin, or part rosin, varnishes and false bodied according to price, for the varnish maker is going to make his profit. We have had too much experience to compare high acid-bearing rosin with fossil gums.

To our minds it is a destructive chemical action which must certainly reflect itself in the durability of the varnish. We are decidedly not standpatters. The old varnishes cannot be compared with a blended varnish combining the best elements of both linseed oil and china wood oil, but we do not want any truck varnishes in our hands. We like to smell some turpentine in our varnish, and when we put on a finishing coat we want approximately 100 per cent pure oil content in the dried out film and not a manipulated one which gives us half the oil and half the durability which we have a right to expect.

STEEL PASSENGER CAR ROOF PAINT

BY F. B. DAVENPORT
Pennsylvania System

The paint maintenance of the steam railway passenger car roof has always been a serious problem from the pioneer day of the good old-fashioned iron-made, tin-roofed car down to the present time modern roof, which may be weather protected with canvas, burlap, wood fibre, paper, or the modern steel plate, which must be service protected with a good paint, usually either of the good old stand-by iron oxide or carbon black pigment made up roof coatings.

There should be no trouble with the modern steel car roof, if originally sand blasted or otherwise freed of dirt, grease, flash, scale or loose corrosive matter and followed up with especially designed paint, which if of good elastic material quality will give a maximum of service results, as practically proven up to date. Regardless of pigment used, a tough, hard elastic varnish-like priming coat should be applied on the roof of the new steel passenger car. Repeated hard, long oil in suitable heavy oil-bearing pigments of fixed, never-changing standards should also be used for all subsequent roof coatings while the car is in service. There possibly may be better roof paints than those made of long oil and the usual calcined oxides of lead, iron and carbon blacks. The committee has attempted to test out several of the so-claimed to be fixed combinations of essential oils, gas coal, asphaltum, pine and kettle bottom tars, fire-flame proofed with asbestos or magnesia fibre. The slower oxidizing oils and pine tar are

undoubtedly most successfully used as oxidizing retarders.

The test committee had the opportunity of investigating the practical service time applied, also the shop test results of several of the new idea tar combined paint or roof cements. The tests proved that regardless of the promoters' claim for the best of these roof cements, the metal surface of the new or old roof had to be thoroughly cleaned and freed of dirt, grease, rust and scale, also that brushed on coats gave better protective wearing results than the heavy knifed-on single coat, also that the mixed-in asbestos or magnesia fibre made a better fire resisting material where reduced almost to a dust. The hard set up and the time continued elastic wearing qualities of these tarry combinations are going to prove worth investigating.

Arranged hot coating tests, also shop practice results show that the use of the best or worst surfacing system priming materials on the new steel passenger car roof is a mistake, owing to the fact that, as a rule, such quick-drying make-up primers will not for any length of time withstand the intense heat of the sun's rays as attracted by the solid metal roof surface. An all-steel passenger car roof is no place for a volatile paint of any kind. It has also been practically demonstrated that it is a mistake to sand the entire metal roof of a steel car, as the applied sand is also a strong sun attractive that helps bleach out the much needed elastic life of the oil in the roof paint. As stated above, all new coatings or recoatings will give better and longer service results where the same formulas of mixed paint stock are used on all protective coatings applied.

THE CHEAP DENATURED ALCOHOLS VERSUS THE GRAIN-PROOF ALCOHOL IN RAILWAY CAR PAINT SHOPS

BY J. N. VOERGE
G. C. & S. F.

Will the future practical tests show that the cheaper vegetable commercial alcohols, lawfully denatured with some solvent mineral spirit, make a dependable substitute shellac varnish for the railway car paint shop? Owing to prohibition, the ban has been put on all things purely alcoholic. The privilege of shop handling grain-proof alcohol, owing to the strict government regulation is a thing of the past.

A good substitute shellac is the cry of the hour. As an offered remedy material, we have many laboratory products of the volatile solvent kind, which include the denatured alcohols, also several of the deodorized acid ether derivatives, including the coal tar by-product ethers; the latter in many cases were found to be more neutral and better solvent gum cutting mixtures than many of the alcohols. The cheaper mineral spirit, vegetable denatured alcohols, in our judgment, made a fairly satisfactory shellac varnish under test. The material dries a little slowly, also was found to be very quick in turning dark where too long exposed to the air in coating application, but we found it would leave a tough elastic shellac film, a tougher film we think than all grain-proof alcohol shellac will leave.

The 10 per cent alcohol denatured cheap vegetable alcohol would make a shellac varnish equal to any requirement of the car paint shop, but its practical use for the purpose is out of the question, which leaves the mineral spirit denatured alcohol shellac the last choice lawfully in the field.

The committee received a gum substitute shellac made up in a fairly deodorized ether that made a strong bid for shop recognition, owing to the fact that the specialty would set up quick and sandpaper finish without tearing equal to any of pure raw shellac cut gum under test. The white and light orange shellac films exhibited represent the mineral spirit denatured alcohol cut shellac still further retarded to show that a quick spirit varnish can be made elastic enough to be taken off in film form.

ARE THERE SUITABLE SUBSTITUTES FOR TURPENTINE? IF SO, FOR WHAT PURPOSE MAY THEY BE USED?

BY C. F. MAYER
C., St. P., M. & O.

Oil or spirits of turpentine, commonly known as turpentine, is obtained chiefly from the long-leaf pine, though a portion is also obtained from Cuban and a little from Loblolly pine. The Forest Service has found that Loblolly, short-leaf and Virginia pines yield equal in quantity to the long-leaf yellow pines, and as the former occur in large quantities in the South their utilization adds largely to the turpentine resources of the country. The turpentine producing area in this country is practically confined to the coastal plains region of the Southern states. In the earlier days the industry was best developed in North Carolina, but, owing to the destructive methods of turpentine orcharding in conjunction with lumbering, fires, etc., the industry has gradually worked southward and westward until at present Florida produces the most turpentine, followed by Georgia, Alabama, Mississippi, Louisiana, North Carolina, South Carolina and Texas.

It is the trade practice to grade turpentine according to its color, and the various grades are known as "Water white," "Standard," "off one shade," "off two shades" and "off three shades." The latter is not merchantable. Under the trade regulations the deduction in price "off one shade" is 2½ cents per gallon, and "off two shades" 4 cents per gallon. Of late years, however, it has become customary to mix the colored turpentine with water-white or standard turpentine, adding a small quantity to each barrel. By this practice the producer receives more for his colored turpentine than he otherwise would under the trade regulations, and but one grade of turpentine is generally known to the buyer. There are, however, properties and methods of production decidedly different in the quality of various lots of turpentine. Recognizing this fact, many users of large quantities buy on definite and rather strict specifications, and it would probably be of advantage to the trade if several grades for turpentine were more generally recognized. The turpentine on the American market is quite frequently adulterated with cheaper and inferior oils, those most commonly employed being the petroleum oils having specific gravities corresponding closely to that of turpentine. Other adulterants are certain coal-tar oils, rosin spirits and wood turpentine which closely resemble turpentine in specific gravity and distilling temperature. Though it is known that spirits of turpentine is very frequently adulterated, to our knowledge no systematic investigation of the subject in this country is on record. The committee is of the opinion that this so claimed indispensable material is not always made on an honest, assured material standard, and is to some extent products of the spirits distilled from the strong poisonous, possibly tannic-charged, hemlock pine, saturated tarry pine tree stumps, pine shavings and sawdust. Odors have been invented in the laboratories so as to make some of the clever products so closely resembling that they can be sold as pure turpentine.

Owing to the extensive use of the various substitutes for turpentine, there should be no scarcity of turpentine. We have not been able to find statistics which show that the source from which turpentine is derived is becoming exhausted, although some people are of the opinion that turpentine will eventually disappear from the paint trade. Chemistry of the highest order is undoubtedly used in the production and commercialization of many of the new by-products, and the paint consumer can rest assured that there is no turpentine source thrown away today.

The committee finds that the only material value of turpentine is its solvent or evaporative powers where used in the painting process. Inasmuch as the turpentine evaporates

after the application of the paint, it ceases after the evaporation to have a material effect upon the character or durability of the paint. When mixed in paint, turpentine may be said to perform one particular service. It enables the painter to apply paint to surfaces with an amount of fixed oil or binding material present that would be too small to give fluid paint and produce the desired flat effect unless turpentine or some suitable substitute were present.

The test committee has made a number of substitute turpentine tests, which were mostly of the fixed or safe gravity mineral spirits order, also of one or two of the smelly coal-tar solvent kind, also some acid ethers. In testing the substitute turpentines, we found that their solvent power varied very much when coming in contact with the several makes of grinding japons we especially selected for test purposes, owing to the idea that the quality of the japan was more to blame for the average substitute turpentine failures than the substitute used. The japons used were a first-class standard make, graded as best shellac, good gum, and soft rosin made-up japons, the quality of each being first class. Of the nine substitute turpentines under test, four samples had solvent cutting power enough to cut the soft rosin japan with but little gum souring in the closed up bottles. The remaining five soured almost uniformly bad. Two out of the nine substitute samples soured badly in contact with the Kauri gum japan, the solvent power of the remaining seven samples only slightly clouded, which proved that the neutral mixing qualities of the Kauri japan were superior to the soft rosin japan. The hard shellac gum made japan neutrally mixed with the entire nine substitutes in a flawless manner, conclusively showing that if the grinding japan is made receptive the best of the mineral substitute turpentines could be exclusively used for all paint and japan color reducing out purposes in the railway car paint shop. If, when adopting the substitute turpentine, you find that it will do everything but clean out a lousy varnish brush, clean out your brush with varnish remover, which is much better and cheaper for the purpose as the cared for remover may be repeatedly used for brush cleaning.

The committee has also tried out five substitutes for turpentine against turpentine in a practical way for all purposes where turpentine is being used, such as fillers, stains, color varnish, flat leads, flat colors for exterior of passenger cars, etc. We find that these substitutes evaporate slower than turpentine, and colors mixed with them do not flat out as quickly as colors mixed with turpentine. They all, however, flat out equally as flat as turpentine, and we find that they are not so slow that it in any way delays the work. We have experienced no trouble in applying varnish over surfaces painted with color mixed with these substitutes. Varnish did not crawl or pit, and flowed out and dried equally as well as varnish that was applied over colors mixed with turpentine. We have been able to carry out the work with these substitutes successfully and apparently equally as well as with turpentine. What the final results from the use of these substitutes will be we are not prepared to say.

From our observations and tests, and from what we have been able to learn regarding the various substitute turpentines that are being placed on the market at the present time, most of them are petroleum products, and it is claimed by those who place them on the market that they are especially refined products absolutely free from grease, sulphur or other chemicals and are of the proper physical property necessary to take the place of turpentine. At one end of the series of petroleum we have gasoline, which evaporates very rapidly and is of no use practically in the preparation of paints. At the other end of the series we have products approaching kerosene, which evaporate so slowly that they also are useless in paints. Between these two extremes, however, it is claimed that there are a series of light petroleum oils which, if

properly refined, are very useful in the preparation of paints. Many of these light petroleum oils, it is claimed, contain a small proportion of non-volatile oil which, if large enough in quantity, will have an injurious effect upon the paint made from them and the painting results obtained. In recent years, however, there has been a marked improvement in the manufacture of light petroleum oil, and it is claimed that some of them are exceedingly useful and produce with fair satisfaction the results which turpentine produces. From our investigation and tests of the various substitutes, we feel that there is a possibility of their being of value, either in place of turpentine or as an addition to turpentine, which at present prices would be a large saving in railway equipment painting. Before, however, the extensive use of substitutes is recommended we feel that it is a problem for the master painter to solve by practical test and results obtained therefrom.

The active paint craftsman should have no regrets at the passing of pure turpentine, as he, as well as the chemist or pharmacist, knows that the volatile gases thrown off from the purest turpentine are deadly poisonous to the human system; in fact, there is nothing more harmful to the confined indoor painter than breathing the pungent fumes thrown off from turpentine spirits. No doubt there is a wide difference of opinion on this subject among the master painters. Most of us have made tests of the various substitutes for turpentine, which have proved to be a complete failure. From our tests and experiments we are of the opinion that a vast improvement has been made in the refining of the products from which substitutes for turpentine are obtained, and the products of five, ten or fifteen years ago cannot be compared with those that are being placed on the market at the present time.

Discussion

W. O. Quest (P. & L. E.). You will find by looking over the samples that there are but two that show up well with the rosin japan, without getting gelatinous or souring. That was a revelation to me. That proved the contention that it might be the form of japan that we used. When we used the Kauri gum we had a little better average. Out of the nine, four of them behaved fairly well. The rest of them soured a little. When you come to the shellac, they are all clear. There was no gelatinous or souring effect. I am not making an issue out of this, but I have always been under the impression that when railroad companies buy what they call Q. D. colors, they should be ground in the best japan procurable. There should never be any cheap japan used; that is, for outside or engine work.

There is a difference in the solubility of the pure turpentine and substitutes, as a rule. In my experimenting I did not find one single substitute that did not have as much dissolving power as pure turpentine.

Another point that might be valuable to present was the coal tar preparations. Coal tar ethers have more solubility than anything we handled, and they could be used in quick drying colors. They get away as quickly as turpentine, and one or two a little quicker than any substitute we have.

It is of course not our object to try to manipulate any one kind of material. In regard to this japan, rosin japan is all right in connection with oil paint. There are few of us who haven't had trouble with putting a coat of paint on today that will lift up tomorrow when you put on another coat. It is nothing else in the world but the soluble japan that causes that. Take a japan that is made with some of your harder gum, and you can put two coats on in a day, and you would not dare to do that with gum of such solubility as rosin japan might develop into. I would not go on record as condemning rosin japan or Kauri japan, but we ought to have something that will dry hard for our body coats on coaches and locomotives.

J. R. Ayers (C. P. R. R.): I have had considerable ex-

perience for a good many years with various substitute turpentine. While I experienced trouble with certain brands, others I have used with entire success with japan colors. At the present time we are using fully 99 per cent of substitute turpentine with absolutely perfect results; we have not had any injurious effects. As far as thinning of oil paints is concerned, with the present rate we are using now, we are getting results equally as good as with pure turpentine. I know of one instance in which we had trouble with material that contained zinc, the substitute was a little higher in sulphur content than permissible to use, and I believe a great deal of the trouble the painters have experienced with substitute turpentine can be traced to the sulphur content of the substitute or the grinding of the japan, the colors which they tried to mix the substitute with.

Mr. D. C. Sherwood (N. Y. C.): We have had several experiences with substitute turpentine, also in the drying of our body colors and it would not dry as quickly as the pure turpentine and after being varnished it would be a different shade, but I feel we can use substitute turpentine, that is, if it is a very good grade. We have had some good and some bad. We can use it in surfacer. We have experienced no trouble at all in thinning down our surfacer, but I don't think we can get along without pure turpentine.

REPORT OF COMMITTEE ON SHOP CONSTRUCTION AND EQUIPMENT

The question of fully equipping a point shop to obtain efficiency, to yield a large output of locomotives, freight and passenger cars, and to insure better means of safety, is a broad matter to which attention of officials should be called. Many of the paint shops today, if equipped so as to represent one of a modernized type, would minimize the time now required for painting a car and would boost the output of finished cars or locomotives, thus making the shop function to its utmost capacity.

One essential part of the equipment that is not available in many shops is stationary scaffolding. Temporary scaffolds may prove to be satisfactory on small jobs or work that requires but little time, but speaking of a shop that has many cars to be turned out in a day, the stationary scaffolds are a necessity. They save many hours a day that could be used by the men in painting cars or locomotives. To move planks and trestles of the temporary type of scaffolds, three or four men have to stop other work. More accidents occur among the workmen who handle such apparatus.

The report is signed by: J. F. Gearhart (chairman), Pennsylvania; G. E. Grammer, Pullman Co.; A. J. Bishop, N. P.

REPORT OF COMMITTEE ON CLASSIFICATION OF PAINTING REPAIRS AND SHOPPING AND EQUIPMENT

The committee reported that the shopping of cars should be determined by the length of time in service or the general condition of car. As a general proposition the class of painting repairs should be determined by the paint foreman on arrival of cars at shops, and should receive treatment according to class of painting repairs, as follows:

SCHEDULE OF CLASS "A" REPAIRS Steel Dining or Private Cars

Outside Operations—Body.

- 1st day—Sandblast and prime with standard primer.
- 2nd day—No operation (dry).
- 3rd day—1st coat of surfacer.
- 4th day—Putty and knife in pitted and uneven surface.
- 5th day—2nd coat of surfacer.
- 6th day—3rd coat of surfacer.
- 7th day—4th coat of surfacer (if necessary).
- 8th day—Rub with rubbing brick and water. (Guide coat previous to rubbing if desired).
- 9th day—Sand and touch up rubbed through spots, if any, with standard primer.

- 10th day—1st coat color.
- 11th day—2nd coat color.
- 12th day—Letter and 1st coat of finishing varnish.
- 13th day—No operation.
- 14th day—2nd coat of finishing varnish (flowed on as full as possible).

Roof and Deck.

- 1st day—Sandblast and prime with an approved pigment and oil primer Allow at least 48 hours to dry.
- Paint roof with two coats of standard roof paint.
- Paint deck with two coats of body color in oil or standard roof paint, according to Railway Company's standard practice.

Trucks, Platforms and Underneath Work.

- Trucks, platforms and battery boxes, paint with one coat of an approved oil paint, followed by one coat of an approved truck enamel.
- Underneath work, paint with two coats of an approved oil paint.

Inside Operations.

- When necessary to remove paint and varnish:
- 1st day—Remove paint and varnish with an approved varnish remover.
- 2nd day—Prime with an approved primer.
- 3rd day—No operation (dry).
- *4th day—1st coat of surfacer of an approved kind and shade.
- 5th day—Putty and knife in pitted and uneven surface.
- 6th day—2nd coat of surfacer, same as before.
- 7th day—3rd coat of surfacer, same as before.
- 8th day—Rub with rubbing brick and water.
- 9th day—Sand and touch up rubbed through spots, if any, with primer.
- 10th day—1st coat of ground color.
- 11th day—2nd coat of ground color, if surfacer is of desired color this operation may be omitted.
- 12th day—Grain.
- 13th day—Varnish.
- 14th day—Stripe number and necessary notices applied.
- 15th day—Varnish.
- 16th day—No operation (dry).
- 17th day } Rub to produce standard finish as required by Railway
- 18th day } Company.

*Surfacer should be of a shade close to the graining ground color.

Head Lining Operations.

- 1st day—Prime.
- 2nd day—No operation (dry).
- †3rd day—1st coat of surfacer.
- 4th day—Sand and 1st coat of enamel.
- 5th day—No operation (dry).
- 6th day—Finishing coat of enamel.
- 7th day—Stripe and ornament.

†If a stippled effect is desired, surface coat should be stippled and a preparatory coat used instead of the 1st coat of enamel, which also should be stippled.

Eighteen days consumed to finish this class of car, followed by two days for trimming, and O. K. on the 21st day.

SCHEDULE OF CLASS "A" REPAIRS Steel Coach

The outside operations on a steel coach to be the same as those used on dining and private cars.

Inside Operation.

- 1st day—Remove paint and varnish with an approved varnish remover.
- 2nd day—Prime with an approved primer.
- 3rd day—No operation (dry).
- 4th day—1st coat surfacer of an approved kind and shade.
- **5th day—Putty and knife all pitted and uneven surface.
- 6th day—Sand and 1st coat of enamel.
- 7th day—No operation (dry).
- 8th day—2nd coat of enamel.
- 9th day—Stripe and ornament, apply necessary notices and number of car with transfers.

**If Railway Company's standard requires graining, operations from hereon will be the same as with the dining car previously scheduled.

Head lining, roof and deck, trucks, platforms and underneath to receive same operations as those scheduled for dining and private cars.

Fourteen days consumed to finish this class of car, followed by two days for trimming, and O. K. on the 17th day.

SCHEDULE OF CLASS "A" REPAIRS Steel Mail, Mail and Baggage and Baggage Cars

Outside Operations—Body.

- 1st day—Sandblast and prime with an approved primer.
- 2nd day—No operation (dry).
- 3rd day—1st coat of surfacer.
- *4th day—Sand and 1st coat of body color in oil, or an oil enamel.
- 5th day—No operation (dry).
- 6th day—Finishing coat of body color in oil, or an oil enamel.
- 7th day—Letter.

*If Railway Company's standard will not permit of above appearance the schedule as applied to coaches, etc. can be applied here.

Roof and deck to receive same operation as those used on dining and private cars.

Trucks and underneath to receive same treatment as dining and private cars.

Inside Operations.

- 1st day—Prime with an approved primer.
- 2nd day—Putty.
- 3rd day—1st coat of an approved coating, standard shade.
- 4th day—No operation (dry).
- 5th day—Finishing coat of oil color or enamel, standard shade.
- 6th day—Paint steam coils and guards, and do necessary stenciling.

Note: The finishing coat for mail, and mail end of mail and baggage cars, to be applied as per specifications issued by the United States Railway Mail Service. Seven days consumed to finish these classes of cars, followed by one day for trimming, and O. K. on the 9th day.

SCHEDULE OF CLASS "A" REPAIRS Wood Dining or Private Cars

The outside operations on this class of cars to be the same as used on the steel type, with the exception that wood cars shall have the paint and varnish burned off.

If the Railway Company's standard does not require the block rubbed surface. Surfacer of the sanding variety should be substituted on the wood sheathed car, and sandpaper used to reduce surfacer instead of block rubbing with stone and water.

Roof and Deck.

Where canvas roof is applied: Roof board joints to be properly leveled, etc., and primed with an approved pigment primer; the following day canvas to be applied in accordance with Railway Company's standard practice. Care should be taken to see that the back canvas is properly coated with an approved canvas roof protective coating and stretched and fastened in place while the coating is still wet, the outside of canvas should then be protected with three coats of an approved canvas roof protective coating.

Deck to receive three coats of body color in oil, or standard roof paint, according to Railway Company's standard practice.

When roof composition is applied that needs no painting, the deck to receive same treatment as stated above.

Trucks, platforms and underneath work to receive same treatment as applied to steel dining and private cars.

Inside Operation.

- When necessary to remove paint and varnish with varnish remover:
- 1st day—Remove paint and varnish with an approved varnish remover.
- 2nd day—Sand and clean up by carpenters properly.
- 3rd day—Fill.
- 4th day—1st varnish.
- 5th day—Stripe, number and necessary notices applied.
- 6th day—2nd varnish.
- 7th day—No operation (dry).
- 8th day—3rd varnish.
- 9th day—No operation (dry).
- 10th and 11th days—Rub to produce standard finish, as required by Railway Company.

Head lining to receive same treatment as applied to steel dining and private cars.

Fourteen days consumed to finish this class of car, followed by two days for trimming, and O. K. on the 17th day.

SCHEDULE OF CLASS "A" REPAIRS

Wood Coach

First-class coaches receive the same treatment accorded dining and private cars, with the exception of rubbing the inside with rotten stone.

SCHEDULE OF CLASS "A" REPAIRS

Wood Mail, Mail and Baggage and Baggage Cars

Outside Operations.

When necessary to burn off old paint, which should be very rare if body color in oil is used, the following operations to be applied:

- 1st day—Burn off paint.
- 2nd day—Sand and clean up by carpenters.
- 3rd day—Prime with an oil pigment primer.
- 4th day—Putty.
- 5th day—Coat with an elastic coating of desired shade.
- 6th day—No operation (dry).
- 7th day—Coat of body color in oil or oil enamel.
- 8th day—Letter.

Roof and deck to receive the same treatment as accorded wood coach. Trucks, platforms and underneath work to receive same treatment as accorded wood coach.

Inside to receive same treatment as accorded steel type of this class of cars.

SCHEDULE OF CLASS "B" REPAIRS

Steel Dining or Private Cars

Outside Operations.

Car to be washed; after necessary repairs are made the following treatment to be accorded:

- 1st day—Prime new or bruised parts.
- 2nd day—Touch up parts with surfacer.
- ***3rd day—Putty and knife in parts.
- 4th day—Sand and 1st color.
- 5th day—2nd color.
- 6th day—Letter.
- 7th day—1st varnish.
- 8th day—No operation (dry).
- 9th day—Finishing coat of varnish flowed on as full as possible.

***If knifed in parts are large they should be rubbed out with block pumice stone and water; this will necessarily require an extra day in schedule.

Inside Operations.

- 1st day—Prime new or bruised parts.
- 2nd day—Touch up parts with surfacer of a shade close to the ground color.
- 3rd day—Putty and knife in parts; same should be of a shade close to ground color.
- 4th day—Sand and ground color parts.
- 5th day—Grain parts.
- 6th day—Varnish newly grained parts.
- 7th day—Varnish all over.
- 8th day—No operation (dry).
- 9th day—Rub to produce standard finish, as required by Railway Company.

Roof to receive two coats of standard roof paint. Deck to receive two coats of body color in oil or standard roof paint, according to Railway Company's standard practice.

Trucks, platforms and battery boxes to receive one coat of enamel. Underneath work to receive one coat of an approved oil paint. Nine days consumed to finish this class of car, followed by two days for trimming, and O. K. on the 12th day.

SCHEDULE OF CLASS "B" REPAIRS

Steel Coach

The outside operations on a steel coach to be the same as those used on dining and private cars.

Inside Operations.

- 1st day—Prime new or bruised parts.
- 2nd day—Touch up parts with surfacer.
- 3rd day—Putty and knife in parts.
- *4th day—Sand and touch up new or bruised parts with enamel.

- 5th day—No operation (dry).
- 6th day—Enamel body and head lining.
- 7th day—Stripe head lining, apply number and necessary notices with transfers.

*If interior is to be grained all bruised parts will have to be given proper ground coat, grained, etc.

Roof to receive two coats of standard roof paint. Deck to receive two coats of body color in oil, or standard roof paint, according to Railway Company's standard practice.

Trucks, battery boxes and underneath work, one coat of an approved oil paint.

Platforms, one coat of enamel. Nine days consumed to finish this class of car, followed by two days for trimming, and O. K. on the 12th day.

SCHEDULE OF CLASS "B" REPAIR.

Steel or Wood Mail, Mail and Baggage, and Baggage Cars

After car is washed and necessary repairs made, the following treatment to be accorded:

- 1st day—New or bruised parts touched up with body color in oil, or an approved primer.
- 2nd day—Putty.
- *3rd day—Sand and 1st coat of body color in oil, or an oil enamel.
- 4th day—No operation (dry).
- 5th day—Coat of body color in oil or an oil enamel.
- 6th day—Letter.

*If Railway Company's standard will not permit of above appearance the schedule as applies to coaches, etc., can be applied here.

Roof to receive two coats of standard roof paint. Deck to receive two coats of body color in oil or standard roof paint, according to Railway Company's standard practice.

Trucks, battery boxes and underneath work, one coat of an approved oil paint.

Inside Operations.

- 1st day—New or bruised parts touched up with color or an approved primer.
- 2nd day—Putty.
- 3rd day—1st coat of an approved coating, standard shade.
- 4th day—No operation (dry).
- 5th day—Finishing coat of color or enamel, standard shade.
- 6th day—Paint steam coil and guards and do necessary stenciling.

Six days to be consumed to finish this class of car, followed by one day for trimming, and O. K. on the 8th day.

CLASS "C" REPAIRS

Steel or Wood Dining or Private Cars and Coaches

Car to be washed. After necessary repairs are made the following treatment to be accorded: Outside of car, new or bruised parts touched up with primer and surfacer, puttied, sandpapered, spot colored and given a coat of color all over, cutting in around lettering, numbering, etc.

Apply one or two coats of varnish, according to Railway Company's standard.

Roof to receive one or two coats of standard roof paint.

Deck to receive one or two coats of body color in oil, or standard roof paint, according to Railway Company's standard practice.

Trucks, battery boxes and underneath work, one coat of an approved oil paint.

Inside Operations.

If wood, touched up and given only sufficient operations to make presentable and maintain Railway Company's standard. If steel, touched up and given only sufficient operations to make presentable and maintain Railway Company's standard.

Six days consumed to finish this class of cars, followed by one day for trimming, and O. K. on the 8th day.

We would recommend that cars having received Class "A" repairs be returned to the shops to receive Class "C" repairs after service of twelve months.

Cars receiving Class "B" or "C" repairs should be returned to the shops at the expiration of 18 months.

This report is signed by: D. C. Sherwood, N. Y. C.; A. E. Green, C. & N. W.; J. R. Ayers, C. P.

REPORT OF COMMITTEE ON SAFETY AND SANITATION

The safety devices in and around railway paint shops is a matter that should interest and attract the co-operation of every man employed. While it is not usually considered a hazardous occupation, nevertheless certain elements of danger enter into the trade and should be carefully checked and, in so far as possible, eliminated.

The scaffolding in our modern shops should be so constructed as to guard against any possibility of collapse; and if mechanical in action, certain absolute devices should be attached to make them sure and safe. All fires, such as open torches or portable furnaces, should be excluded from the paint shop, for the nature of the materials used are of volatile and spontaneous mixtures and easily ignited. Nearly every paint shop fire has been directly traceable to this source.

The protection of employees when working on cars in repair yards is important, and the tracks should be equipped with caution signs of an absolute character. If possible, switches leading to repair tracks should be locked and a

blue flag displayed reading "REPAIR MEN." These flags should not be removed except by those directly in charge of the gangs who are doing the work. Each man should be instructed to see to it that such protection is in place before proceeding with his work. Most railroads make this rule imperative when employing men.

Workmen who are asked to clean and scrape rust off of steel cars should be furnished with goggles for eye protection. Chain hoists used for handling and unloading barrels, etc., should receive frequent inspection. Stepping on nails is very frequent and sometimes results in serious consequences; it is therefore very essential that rubbish of all kinds be removed and deposited in receptacles specially provided for this purpose.

Sanitation

Sanitation of shops and surroundings is one of the most paramount features necessary to establish an efficient organization. Nothing so impairs the efficiency of men as unhealthy surroundings. Very frequently better places are discarded or left vacant than buildings erected for men to work in. The purpose of this report is to point out some few conditions which would tend to weaken an organized body of men and thus lessen their efficiency, and suggest a few more favorable conditions which would tend to build up a healthy, happy and efficient group of workmen.

The buildings, in so far as possible, should be made and placed so as to guard against unsanitary conditions, furnished with good sewage, plenty of air spaces, well ventilated and sufficient heat units to keep the temperature even. Doors and windows should be so placed as to guard against insufficient circulation of fresh air at all times. If possible, all openings should be screened in order to keep out the dreaded germ carriers. Floors should be so constructed that water will drain off, thus preventing a possibility of breeding places for mosquitoes, etc. A room measuring 18 ft. by 24 ft., making a floor area of 432 sq. ft., should contain four windows measuring 3 ft. by 6 ft., a total window area of 72 sq. ft. Natural illumination is that provided by the direct rays of the sun or light reflected by the sky. In factories, workshops and other places in cities where daylight illumination is reduced by the walls of neighboring buildings, an increased illumination may be obtained by the use of ribbed glass, which causes a larger portion of the light to be refracted into the building. Windows should always be kept clean, as the amount of light entering the room may be reduced 40 per cent by dirt upon the glass. With modern illuminating units and suitable reflectors a current consumption of about one watt to each square foot of surface should yield an intensity of four-foot candles. Every effort should be made to prevent a glare, as glare makes seeing difficult and soon impairs the eyesight, thus further interfering with the efficiency of the workmen.

Dust is the arch enemy of the paint-shop workman. It may be of organic or inorganic origin. The inorganic dust is what is most dangerous, and we must guard our workmen against the dust from the sand-blast machine. For dust from this source is severe on the throat and lung tissues. There are numerous ways to accomplish this. Somerfeld, in the following table, gives some idea of the injurious effects and the death rates per thousand from consumption of persons engaged in various trades where dust is a prominent factor:

Occupation without dust production.....	2.49
With dust production	5.42
With porcelain dust	14.
With iron dust	5.55
With lead dust	7.79
With stone dust	34.09
With stone workers	4.03
With wood and paper dust	5.96
With tobacco dust	8.47

Dust containing sharp, gritty particles, such as present during cutting of hard rock, sets up a chronic irritation of the air passages which then become favorable lodging places for the germs of consumption and kindred diseases. The

bad effects of dusty working places may be obviated by the use of respirators. These are, however, rather uncomfortable to wear, so the better way is to remove the dust at its source by some mechanical device or prevent its accumulation in the air by the use of water.

Those who are compelled to work in white lead should use great precaution regarding cleanliness. A workman should never eat or handle food without first thoroughly cleansing his hands, for lead is more often carried into the system through this process than in any other way. Lead poisoning has become so great a menace among workmen that the State Boards of Health and Labor Bureaus are making a very exhaustive examination of the causes and prescribing ways and means of averting its ravages.

Painters stenciling cars where it is necessary to hold the stencils with the fingers should use some form of protection. The use of finger ends from rubber gloves is a simple and effective expedient. Dr. Robert Jones, reporting in 1900 upon 3,500 males admitted to the London county asylum for the insane, found among them 133 artisans who had been exposed to plumbism; painters, 75; decorators, 13; plumbers, 18; gasfitters, 13; laborers in lead, 6; grainers, 3; gas meter makers, 2; color grinders, 1; file cutters, 1, and tea lead rollers, 1. It seems that whatever we can do to allay the possibility of lead poisoning should, by all means, be done.

There are only two ways to come in contact with paint and its effect on the health of men: by actual physical contact, and by inhalation; and both of these can be almost entirely eliminated, one by the painter himself and the other by shop construction. The careful painter will always avoid getting paint all over his hands and face, and we should see to it that the other, ventilation, is given him.

Paint Spraying Machines

The spraying machine is one of the most economical and efficient means of applying paint to all freight cars, running parts of locomotives, trucks and underframes of passenger cars. It is the experience of the committee that a freight car can be painted at about one-fourth the cost for labor by use of a spraying machine. The cost of labor saved is not the only item to be considered. Freight cars can not be painted until after repairs are completed, and to maintain a force of painters of sufficient size to paint cars by hand after cars are repaired would mean that during a large part of the day these painters would be idle. By using spraying machines a small force of painters can do the work and can be profitably employed during the early part of the day at necessary small jobs.

Since the spraying machine is both economical and efficient, we should use all means to overcome the only possible objection to it, make its use free from fume effect. We would suggest that all work be done out of doors as much as possible. Freight cars can be and usually are painted under a shed, and many shops do not even have a shed. The next thing is to use a spraying machine with a long barrel or "gun" that not only makes the use of scaffolds unnecessary but puts the paint up close to the work and away from the operator.

The report is signed by: W. A. Buchanan (chairman), D., L. & W.; J. S. Gilmer, Southern; C. D. Beyer, L. & N.

MACHINERY EXPORTS TREBLE IN SIX YEARS.—In 1913 the total exports of machinery were valued at \$127,980,000, while in 1919 they reached a total value of \$378,425,000. That the total in the latter year was not greater was due to the urgent home demands for machinery of almost every description, which limited the amount available for export. One large manufacturer declared recently that his foreign orders for the first six months of the present year were more than 60 per cent greater than during the same period last year.—*The World Markets.*

Banquet of the Tool Foremen's Association

CONVENTION OF THE TOOL FOREMEN'S ASSOCIATION

**Standard Staybolt and Boiler Taps Agreed Upon;
Proposal to Amalgamate With A. R. A. Sec. III Adopted**

THE American Railway Tool Foremen's Association is the second of the so-called minor mechanical department organizations to take definite action on the question of amalgamation with the American Railroad Association, Section III—Mechanical. The Association voted definitely to accept the invitation of Section III—Mechanical to become a part of that organization, at the tenth annual

STANDARDIZATION OF BOILER AND STAY-BOLT TAPS

Fig. 1 shows a 36-in. tap with Whitworth threads, 12 per in., which is carried by tap manufacturers throughout the United States in regular stock. There is also made, to the same standard, spindle tap and spindle which is used

convention, which was held at the Hotel Sherman, Chicago, September 1, 2 and 3.

The convention was called to order by the president, J. C. Bevelle (El Paso & Southwestern) and, following the usual opening exercises, proceeded immediately to the consideration of the technical reports and papers on the subjects assigned for investigation at the last convention. Abstracts of the papers and the discussion which took place at the meeting are given below.

for the same purpose as the 36-in. tap. This tap, known as style two, has been used to good advantage for applying staybolts back of the frame. These taps are 12-thread Whitworth and are manufactured by the S. W. Card & Company, or by Charles Besly & Company. Our reason for recommending the adoption of these taps is the fact that they are at present used successfully on many railroads and are giving better results than other types. The Whitworth thread has a greater tensile strength and maintains its original

diameter longer than the V or the United States Standard forms of thread.

A standard 24-in. staybolt tap is also required. This tap is also 12-thread Whitworth. These taps are at present carried in commercial lengths of 21 in., 22 in. and 24 in. We recommend the 24-in. tap because the reamer portion is extra long, giving a greater length and smaller diameter on the point, so that, when tapping from the outside, the small end of the tap protrudes through the inside sheet and acts as a guide, making it much easier for the operator and assuring a good thread on both the outer and inner sheets. The taper threaded portion of the tap has been lengthened,

Size of Tap	Threads to inch	M	N	O	P	Q
15/16	12	13/16	15/16	13/16	11/16	5/8
1"	12	7/8	1"	7/8	3/4	11/16
1 1/16	12	15/16	1 1/16	15/16	13/16	3/4
1 1/8	12	1"	1 1/8	1"	7/8	13/16
1 3/16	12	1 1/16	1 3/16	1 1/16	15/16	7/8
1 1/4	12	1 1/8	1 1/4	1 1/8	1"	15/16
1 5/16	12	1 3/16	1 5/16	1 3/16	1 1/16	1"

Fig. 1—Radial Staybolt Tap

making the life of the tap much longer as well as eliminating a great deal of wear and tear on the air motor and consequently making it easier on the operator. We recommend that these taps be furnished in sizes from 15/16 in. to 1-5/16 in., advancing by sixteenths if possible. We find that these sizes will conform to the government rulings, making 15/16 in. the smallest bolts and 1-5/16 in. the largest. These taps are all to be 12-thread Whitworth and should be furnished over-size with a minimum of .0015 in. and not to exceed .0035 in. This will take all standard makes. The number of threads per inch should be 12 and in a distance of 6 in. there should not be more than 60 3/4 threads or be less than 59 3/4. The staybolt cutting machine should be checked very closely and the diameter kept to a standard so that the threads cut on the staybolt will be as accurate as the tap.

Fig. 2 shows a standard button head radial staybolt tap.

Fig. 2—Button Head Radial Staybolt Taps

This tap is now commercially manufactured and is used very successfully on many railroads. It has a taper of 1 1/2 in. and is 12-thread Whitworth. This tap is used for applying button head radial staybolts in the crown sheets of locomotives.

Fig. 3 shows boiler head and washout plug taps. These taps should be tapered 3/4 in. in 12 in. and have 12 threads

per inch, United States Standard. One taper and one thread should be maintained in all washout and mud plug holes. It has been found that taps made with this taper give excellent results, not only assuring a good tight plug, but one that is safe. We find that 3/4-in. taper in 12 in. is far more desirable than 1 1/2 in. and believe that it will eliminate the blowing out of washout plugs.

Fig 4, shows a special washout or mud plug tap. This is only used in emergencies or in roundhouse service where it

2	2 1/8"	" "	" "	
3	2 1/4"	" "	" "	
4	2 3/8"	" "	" "	

Fig. 4—Special Washout Plug Tap

low the other, the sizes being designated on the large end. The taper tap is recommended instead of the straight tap for boiler studs for the following reasons: First, we can get a more secure stud with the taper thread tap than with the straight thread tap; second, there is less liability of a leaky stud. It must be understood that when taper studs are applied they must penetrate the sheet. It is now the practice on many railroads to use a tap similar to the one described.

If these taps are adopted as standard they will eliminate

many irregularities that now exist on the railroads throughout the United States. Furthermore, it simplifies the manufacturing of taps for this particular class of service. At present these taps can be secured from any first-class manu-

a machine at too high speed or too great a depth of cut, resulting in excessive wear or breakage, the time consumed in changing, re-setting or repairing overbalances the time gained by the increase of speed or depth of cut.

facturer at a much more reasonable price than they can be manufactured locally in a railroad shop.

The report was signed by E. J. McKernan (chairman) W. Wood, W. Perkins, J. N. Meek and H. E. Barnes.

Discussion

The question of what type of thread for staybolt taps will give the best results brought out a general discussion. The comments of the members indicated that comparatively few railroads have adopted the Whitworth thread recommended by the committee, while about an equal number appeared to be using the V thread and the United States Standard thread. Expressing their personal opinions, however, few of the members considered V threads as satisfactory as either of the other two kinds and the prevailing sentiment indicated that the Whitworth is the most desirable of the three types. Tests were referred to in which the pulling strength of the Whitworth type in the sheet has been demonstrated to be greater than either of the other two forms and the circular shape of the cutting edges of the Whitworth tap is less affected by wear than either of the other two, both of which have sharp corners. Taps with the V thread have been found to lose as much as .003 in. in diameter in tapping one hole under the heavy drive which these taps must withstand under modern conditions. Where a railroad makes its own taps, however, which is frequently done in the case of the plug and stud taps, either the United States Standard or the V type threads are more easily formed. For this reason the committee recommended the United States Standard type for plugs and stud taps.

HEAT TREATMENT OF STEELS

Heat treatment is the most important operation that our tools have to pass through. Shop output depends very largely on the quality and quantity of small tools. To get maximum shop output every tool and machine must be giving maximum production, which means that it is completing its operation in the shortest possible time and is keeping this up for a maximum period of time. These two factors are dependent one upon the other. If we operate

The moral effect on the men in the shop of properly heat treated tools goes farther toward getting a maximum shop output than any of us can imagine. It is a factor which cannot be expressed very easily by figures. We have absolute control over the design of the tool, but can we say what its performance will be after it has been treated and ground up ready to put in service? If we have the proper equipment we can say yes for a very large per cent of our tools.

To obtain the best possible results from the heat treating plant there should be a spirit of close co-operation between it and the department using the tools. In other words, the one in charge should have a thorough knowledge of their performance in service. The best way for this condition to exist is for the tool foreman to have actual charge of the treating plant. This has been done in a great many shops. The heat treating plant should be in the manufacturing department, which would reduce the lost motion and the overhead charges in transporting tools to and from the heat treating furnaces.

HEAT TREATMENT

Owing to the general makeup or composition of tool steel, which is unlike pure iron or other similar metals, it must be properly and carefully handled in the heat treatment to obtain best results and prevent losses.

There are three general heat treatment operations: annealing, hardening, and tempering. In all of these the object sought is to change in some manner the existing properties of steel; in other words, to produce in it certain permanent conditions.

The controlling factor in all heat treatment is temperature. Insufficient or excessive temperatures do not produce the results sought. Excessive temperatures, either through ignorance of what the correct point is or inability to tell when it exists, may cause burned steel. This is a common failing, resulting in great loss. Slight variations from the proper temperature may do irreparable damage. Steel that has been burned is useless and cannot be restored by annealing.

In the actual heating of a piece of steel several requirements are essential to good hardening. First, the small projections or cutting edges must not be heated more rapidly than is the body of the piece; second, all parts must be heated to the same temperature, as low as will give the required hardness to produce the best results.

Any temperature above the "critical point" of steel tends to open its grain, to make it coarse and to diminish its strength. The temperatures at which the internal changes in structure of steel take place are frequently spoken of as the "critical" points. These are different in steels of different carbon contents. The critical points may be observed by watching closely the slow heating of a piece of steel in the furnace. At first the temperature of the steel gradually increases with the heat of the furnace until a point is reached at which it appears a little darker and cooler than the furnace, then as heating continues the piece again assumes the color and temperature of the furnace. This critical point is termed "decalescence." A similar change may be noted in cooling down the furnace, during which process at some point the piece of steel may become brighter and apparently hotter than the furnace, and later assume again the temperature of the furnace. This is known as the "recalescence" point. The temperatures of the critical points are usually dependent on the percentage of carbon.

Great care should be exercised in heating tool steel for forging as well as hardening or tempering; this is especially

true of high speed steel. Take sufficient time, depending on the size of the piece, to give it a thorough soaking heat, up to the proper temperature, but do not overheat.

The exact treatment varies for different steels and it is usually advisable to follow the directions given by the steel makers.

METHODS AND EQUIPMENT FOR HARDENING AND TEMPERING

It has not been long since heat treating as well as forging and dressing tools was entirely handled in the blacksmith shop by old methods. Results depended on the ability of the tool smith and the attendant varying conditions. The principal factor, temperature, was governed by observation of the color both when hardening and drawing. Today most of the railroads are using up-to-date methods and equipment, especially in their large shops, where centralized manufacture of tools is carried on.

Unquestionably the proper location for heat treatment of tools at shops where any considerable amount of this work is done, is in the tool room. It is important that, in order to handle this work successfully, the men in charge have a knowledge of the material and proper methods of handling, and be provided with the suitable equipment, such as furnaces, heat

Some of the best builders of furnaces today are prepared to furnish very desirable equipment, either standard or built to specifications, and there is available complete matter in the way of description and prints on both the electric furnaces and those using other fuels, so we will not take space here to describe each in detail.

The nature of the work, the size or shape of piece to be hardened, makes desirable at times the use of different processes or kinds of heating mediums, as, in addition to the plain electric, gas, oil or coke oven, the bath furnace is found very convenient for long articles, such as stay bolt taps, long reamers, etc. The material used for the bath usually is lead, or a salt mixture, such as barium chloride, etc., each having some advantage over the other. This form of hardening is much in favor for a lot of work done in the tool room, on account of the ability to heat only that portion of the tool desired, and exclude all air from the heated part, thereby eliminating danger of scaling, which exists with almost any other means of heating.

The quenching of the heated article is an important operation and in too many cases is not given the consideration and attention it should receive. The tanks should be of ample size and it is often necessary, if much work is

Hardening and Tempering Room, Illinois Central, Burnside Shops, Chicago

gaging apparatus, hardness testing instruments and so forth.

There are several types of furnaces which may be used for heating tool steel and the kind selected would depend considerably on the shop conditions and the kind of fuel available. Good results are obtained from furnaces using electricity, gas, oil or hard fuel, such as coke or coal, as heating mediums; the first two mentioned are no doubt the most popular and efficient for tool work. Any fuel-burning furnace for this work should be so constructed that the flame does not come directly in contact with the article to be hardened. This can easily be arranged through use of a combustion chamber in connection with suitable design and construction of the heating chamber. There are several different designs which may be used for each of the different fuels, but they all should produce as nearly as possible the ideal condition for the heating chamber where the work is placed. The size will be governed by the amount and size of the articles to be hardened.

done, to have more than one in order that the quenching liquid may be maintained at an even temperature. The uniform hardening of heating tools depends greatly on the uniform temperature of the quenching mixture and, where one tank or more is used, a good arrangement is to have the quenching tank inside of another tank of water and to keep the quenching medium stirred up by air through a submerged pipe or by mechanical means. Oils, brine and clear water are used as quenching mediums, and the temperature may be raised or lowered as desired by means of steam or water pipes, but it should be kept uniform for each batch of tools and for all similar work.

In the hardening operation the steel should be quenched on the rising temperature.

The use of air for hardening high speed steel is also necessary in addition to the liquid and it is best to have a good valve in connection with a compressed air line to regulate the pressure.

For some time past the oil bath has been generally used for drawing back and it is preferable to the old way of drawing by observing the color of the tool. There is also in use for this purpose the electric oven, which is comparatively new and in several ways superior to other equipment for this work.

TEMPERATURE MEASUREMENT

In all the heat treatments of steel, and especially the heating of tool steel for forging, hardening or drawing, the most valuable asset of the hardener is the knowledge of proper temperatures for the various kinds of steel and a sure and convenient means of determining those temperatures. The information regarding the proper temperature for a certain kind of steel is easily obtained and it is considered good practice to follow the instructions of the steel manufacturer for his product. The only safe way to measure or determine the temperature in the future or bath is by the use of good electrical or optical pyrometers. The practice of depending upon the naked eye to tell the temperature of a furnace or a tool by its color is not productive of good results, no matter what kind or how good the steel may be.

Pyrometers may be used in connection with almost any kind of furnaces and it is well to have a master pyrometer for comparison in checking the service instrument. These are not complicated nor expensive devices when compared with the service they render. They are, however, somewhat delicate and should be handled accordingly. The pyrometer may be tested for correctness by the simple salt-cooling process, or will be calibrated by the manufacturer or by the United States Bureau of Standards for a nominal sum. The pyrometer must be kept accurate at all times, as variation either way of several degrees would render it as good as useless for temperature determination; therefore, check your instrument frequently.

HARDNESS MEASUREMENT

There is still another instrument which, by all means, should have its place in the complement of equipment for heat treatment of tool steel. This is the scleroscope. There are other methods of testing the hardness, which no doubt are equally as good for some kinds of work, but the scleroscope seems to be best suited for tool room use. There should be a record kept of the heat treatment of all tools made. This may best be in the form of a card record for ready reference and should contain such information as kind of tool, make and grade of steel, temperature given for hardening, time in furnace, quenching medium used, drawing temperature and time, and scleroscope hardness. To this may be added remarks relating to the performance of the tools in service.

This will be very valuable information for the tool man. It will enable him to make corrections from time to time in the treatment of steel, or of defects which may be a result of having it too hard or too soft for the purpose for which the tool is used. The report was signed by C. A. Shaffer (chairman), H. Otto, P. Renfrew, W. J. Hines and F. C. Courson.

Discussion

During the discussion, Professor Kinsey, of Stevens Institute of Technology, Hoboken, N. J., gave an interesting talk on the principles of heat treatment of steel, bringing out clearly why uniform results cannot be expected from tools which are heat treated in the open fire of the blacksmith's shop and the eye depended on to measure temperature by color determination. Professor Kinsey pointed out that the transformation which causes hardness on quenching takes place at the decaescent point, which occurs within the narrow range of about 54 deg. If this temperature is not reached the complete transformation will have not taken place, while,

on the other hand, if this temperature is exceeded a change takes place which immediately begins to increase the grain size thereby seriously weakening the material. He pointed out the practical impossibility of accurately determining temperature within this narrow limit by color determination, which is effected by changes in the light of the shop.

The fact that there are not as many skilled toolsmiths at the present time as used to be employed in the blacksmith shop was mentioned as an additional reason why suitable furnace equipment fitted with pyrometers is more essential now than ever before if satisfactory tool service is to be obtained. Where this work is specialized it is not essentially a blacksmith's job, as a good heat treater need know nothing about the details of the blacksmith trade.

The importance of careful attention to furnace conditions was also touched on from several different angles. Several cases were mentioned where failure to secure proper hardness was experienced, for which there seem to be no apparent cause. The discussions indicated that these cases are frequently due to carbonization of the surface of the material caused by the flame playing on the tools. This frequently insulates the material, thus preventing a uniform temperature being attained throughout the piece. Similar results have been caused by oxidation or de-carbonization of the surface, thus producing a soft exterior which can only be corrected by removing the surface metal and rehardening under proper conditions. Burned steel has also been found to be more the result of improper furnace conditions than of the actual temperature to which the material has been heated. If oxidation can be prevented the temperature has little effect on steel which cannot be removed by annealing and retreating.

JIGS AND DEVICES FOR LOCOMOTIVE AND CAR SHOPS

At the Roanoke, Va., shops of the Norfolk & Western, a 300-ton wheel press, with 13-in. ram, unexpectedly developed a bad place in the copper lining and a new liner had

Rollers for Applying Copper Lining to Wheel Press Cylinders

to be rolled in place at once. The part of the press to be worked on was brought to the machine shop and placed on the table of the locomotive cylinder boring machine and

rollers with 2-in. faces were placed in the tool slots of the boring head, with a taper pin in the center to expand the rolls uniformly.

The work proceeded nicely while feeding in on the first rolling, but on feeding out it was discovered that the liner was stretching and moving out and, when complete, the job was not as satisfactory as could have been desired, due to the

Method of Operating the Rollers

creeping of the material as the rolls passed over the surface.

As a result of this experience a roller was made having five rolls, $4\frac{1}{2}$ in. in diameter at the large end and extending into the cylinder 31 in., the entire depth of the copper liner, with a taper of $\frac{1}{8}$ in. in 12 in. A taper pin of sufficient

Prony Brake Used for Testing Air Drills

diameter to expand the rolls the required amount was operated by a ratchet lever and bar, and forced between the rolls with the aid of the twin ram at the other end of the press.

With this device the liner was rolled into place in a very

satisfactory manner by simply removing the ram and the old copper liner and inserting the new liner and putting the roller in service. The work was finished in perfect condition and ready for service in five hours.

TESTING PNEUMATIC DRILLS FOR PULLING POWER

When a pneumatic drill has been sent to the shop for overhauling, there should be some method of determining whether it has been improved by the operation and what per cent of its normal power it is exerting. In order that the machines could be checked before leaving the shop the ap-

Fig. 1—Milling the Grooves in Flue Cutter Knives

paratus shown in the photograph was designed for use at the Roanoke shops of the Norfolk & Western.

It consists of a spindle and brake wheel in a frame, to which the drill can be attached in the manner and with the same effect as when drilling a hole. The brake lever can be loaded to get any desired resistance within the capacity of the machine.

By making a record of each class of drill when new, it is always possible to determine what per cent of its rated capacity it is exerting.

MAKING FLUE CUTTER KNIVES ON A MILLING MACHINE

Flue cutter knives which were formerly made at the Battle Creek, Mich., shops of the Grand Trunk, partly by machinery and then finished by hand, are now made entirely

Fig. 2—Milling the Angles on Flue Cutter Knives

in the milling machine and the time required has been reduced about one-half.

The first operation is to cut the bar stock in suitable lengths to make about twelve knives. The square stock is then put in centers and straddle mills are used to mill to the required size, which is $\frac{3}{4}$ in. square. Then the stock is cut to the proper length to make the knives. The grooves are then milled in, as shown in Fig. 1. After this operation

is finished, the knives are put in a vise, using the device shown in Fig. 2, and the angles are milled. The rack cutting attachment is then used, as shown in Fig. 3, placing the knife in the device as shown and using twin mills to cut the point down to the proper width. The device is placed in the vise on the index head and the tail stock center is used as a clamp, using the index handle to turn the head.

Fig. 3—Milling the Cutting Edges of Flue Cutter Knives to Width

After the points are milled, the straddle mills are removed, another cutter put on, and the other ends milled to the proper circle.

The papers on this subject were prepared by the following committee: J. J. Sheehan, chairman; P. L. Watson, J. J. Sumner, Thos. Bell and R. E. O'Hern.

Discussion

Following the presentation of the papers on this subject it became evident from the discussion that there are few tool foremen who do not have a number of special devices which they have developed for various operations in their shops. The importance of this field as a matter for the systematic consideration of the tool foreman was stressed by several members. The future of the tool room foreman lies, not in his ability to turn out satisfactory small tools and machine tool cutters, but in the extent to which he studies the problems of the other departments of the shop with a view to the development of special jigs and tools to reduce the time and labor required on machine and erecting floor operations.

ISSUING AND CHECKING TOOLS IN LOCOMOTIVE AND CAR SHOPS

BY J. B. HASTY,
A. T. & S. F.

Employees entering the service are required to sign a card form in duplicate. The original is retained by the foreman and the duplicate by the employee. Six tool checks, a hammer, monkey wrench and three chisels are furnished and entered on his card, which he retains until he leaves the service. The main tool room is located in the center of the machine shop. There are also sub-tool rooms in the boiler shop and car shop. All new or repaired tools are distributed to the sub-tool rooms from the main tool room. All small hand tools are grouped in racks with the sizes stenciled on the racks; small hooks are provided to hang the checks. Checks must be presented for all tools in the tool room, except chisels and machine tools. A supply of these is kept in the tool room and exchanged as they require redressing.

When chisels become too short for further use as chisels, they are made into center punches, drill drifts and other small tools. Machine tools are of standard sizes and when two-inch by three-inch tools become too short for further use, they are made into smaller sizes until they are worked down to $\frac{1}{4}$ in. by $\frac{1}{4}$ in. for Armstrong tool holders. Tools

that require redressing are delivered to the smith shop each morning and returned to the tool room in the evening, ground and placed in racks for distribution. Pneumatic tools are returned to the tool room each evening for inspection and oiling. All tools must be turned in before quitting time on Saturday. A record is made of all checks left in the tool room over Sunday and the employees involved are taken to task for not obeying rules.

Shop goggles are kept in an inclosed case, checked out and sterilized as they are returned. If tools are lost, broken or damaged by an employee, he is required to get a clearance card properly signed by his foreman before his check is returned to him. An employee leaving the service is required to return the tool checks and tools recorded on his card to the tool room foreman, who checks them up and, if there is no shortage, signs the order for his time. In case of a shortage, explanation is demanded and unless he can give a good reason for the shortage the cost of the missing tools is deducted from his pay.

Discussion

Most of the members who took part in the discussion of this paper are using systems of issuing and checking tools similar to that described, varying in details or supplemented by periodical inspections of cupboards as a check on the operation of the system. In some cases, instead of permanently assigning cutting tools to the men, they are assigned to the machine, with a supply in the tool room for the use of men on the night shift. The importance of the tool room foreman securing the confidence of the men and of the other foremen was touched on by several members. This is necessary in order to secure the co-operation of the men in returning the tools to the tool room at the end of the job or of the day, according to the rules of the shop, and to insure that the foremen will not let irregularities pass unnoticed. In one case the monthly inspection of the shop made by the local safety committee is also utilized to locate broken and misplaced tools. To avoid the opportunity of forgery an annual change in the form of tool checks is also made in some cases.

Other Business

During the second session of the Convention H. H. Lavercombe, President, Tool Salvage Company, Detroit, Mich., described what is being done by his company in salvaging worn out milling cutters by a secret grinding process, without the necessity of heat treatment. He also referred to the method of restoring slightly worn straight flute reamers to size by a hot pressing process developed by his company.

During the closing session of the convention a moving picture showing the proper use and the abuses of twist drills was shown by the Cleveland Twist Drill Company.

The following officers were elected for the coming year: President, J. B. Hasty (A. T. & S. F.); first vice-president, G. W. Smith (C. & O.); second vice-president, Charles Helm (C. M. & St. P.); third vice-president, Geo. Tothill (B. R. & P.), and secretary-treasurer, R. D. Fletcher (Cruible Steel Company). The following were elected members of the executive committee: P. Renfrew (Big Four), chairman; T. W. Henson (Wabash), E. A. Westerman (Indiana Harbor Belt), C. Dangelmeyer (C. M. & St. P.) and C. C. Kuyper (Illinois Central).

The association voted to hold the next convention at the Hotel Sherman, Chicago.

RAILROAD CONSTRUCTION IN CENTRAL AMERICA:—Negotiations for a railroad connecting Guatemala City and Salvador which were suspended during the war, have now been resumed. The projected road will extend from Zacapa southward 157 miles to Salvador. About three years will be required to complete the work.

TOOL WAGON FOR THERMIT WELDING MATERIALS

The accompanying sketch shows a new and improved tool wagon for holding all materials and appliances for thermit welding which has been designed by the Metal and Thermit Corporation, New York. The new design provides a place for the thermit preheater at the side of the crucible. The tool wagon also contains a tool box for all necessary tools, space for mold boxes and a bin for molding material divided into two parts, the upper one for facing material and the lower for backing material. A sand screen is provided in the lower part of the lid for screening molding material when a mold is broken up to prepare it for the

The Wagon Carries Everything Needed for Making a Thermit Weld

next weld. During the screening of sand this lid is closed.

The following list shows the arrangement of the parts in the wagon:

- A—Drawer for spring balance, hammer, chisel, monkey wrench and Stillson wrench.
- B—Shelf for bolts and nuts, nail puller, double-end wrenches, leaf and long spoon, thimbles, ignition powder and gloves.
- C—Shelf for trowel, lifter, screwdriver, pliers, slick, plugging material and vent wire.
- D—Compartment for crowbar, hot blast furnace, gas, torch, rammer, mold box parts, patterns, shovel, sledge, wax in box, flaming burner and crucible holder.
- E—Compartment for facing sand.
- F—Compartment for molding sand.
- G—Adjustable clamp for Nos. 5, 6 and 7 crucibles.

This wagon is 42 in. wide, 57 in. high to the top of the tool box and its length, exclusive of the handle, is 7 ft. 5 in. A blueprint showing the design and dimensions in more detail than the accompanying sketch can be secured from the Metal and Thermit Corporation.

MACHINE TOOL EXHIBITION IN ENGLAND

LONDON, Eng.

The machine tool industry of Great Britain not having the opportunity of exhibiting its products at the meetings of any of the engineering societies, in the manner so common in the United States, but at the same time realizing the advantages of putting on show its products, arranged a three weeks' exhibition, during September, of machine tools at "Olympia," a large exhibition hall in London. The exhibition was handled by the Machine Tool Trades Association. It was a well organized affair and full of interest to the engineering industry in Great Britain. Many of the machine tools exhibited gave actual demonstrations of the work they were designed to perform. The exhibition was open from 10.30 in the morning to 9.30 in the evening and an admission fee of two shillings (40 cents) was charged,

but a large number of complimentary tickets were distributed to the trade by the exhibitors.

In connection with the exhibition two conferences were held during the last week. On Tuesday, September 21, there was a conference of employers and employed which was arranged by the Industrial League and Council during which the following subjects were discussed: "Unemployment and Production" and "High Prices and World Competition." On Wednesday, September 22, there was an Industrial "Safety First" conference held under the auspices of the Home Office and the British Industrial "Safety First" Association. On this day the morning session was presided over by the Rt. Hon. Edward Shortt, Secretary of State, Home Department, and the following papers were read: "Safety First and its Application to Industry," "The Safeguarding of Machinery" and "First Aid in the Factory." The afternoon session was presided over by Lord Leverhulme, president of the association, and papers were read on "Health, Hygiene and Safety First," "Why and How We Introduced Safety First Methods," "Notes on Safety First for a Large Factory," "Safety First in a Steel Works," "Observations on a Works Safety First Scheme," "Safety First as Applied at Port Sunlight" and "Lighting as an Aid to Safety."

A very complete catalog of some 420 pages was sold in the hall for one shilling (20 cents.) This catalog contained a complete list of all the products shown by the various exhibitors and a good deal of space was given to advertising these products.

The exhibition hall consists of a ground floor, on which was exhibited the heavy machinery, and a gallery on which were exhibited the lighter products. There were in all 167 exhibition booths. The exhibition included machine tools manufactured in Great Britain and a large number of machine tools of other countries which are handled by the machine tool agents in Great Britain. Of these American tools form by far the greatest majority. As a matter of fact the American tools were a relatively large proportion of all the tools exhibited. There were a few Swiss, French, Danish and Swedish tools shown, but no German tools.

Among the American machine tool builders represented may be mentioned the following:

Baush Machine Tool Company
 Becker Milling Machine Company
 Brown & Sharpe Manufacturing Company
 Bullard Machine Tool Company
 Carborundum Company
 Chicago Pneumatic Tool Company
 Cleveland Twist Drill Company
 Colburn Machine Tool Company
 De Vilbiss Mfg. Company
 Dixon Crucible Company, Joseph
 Foster Machine Company
 Geometric Tool Company
 Gisholt Machine Company
 Gould & Eberhardt
 Greaves-Klusman Tool Company
 Heald Machine Company
 Ingersoll Milling Company
 Jacobs Mfg. Company
 Kearney & Trecker Company
 Landis Machine Company
 Landis Tool Company
 Lapointe Machine Tool Company
 Le Blond Machine Tool Co., The R. K.
 National Acme Co., The
 Newton Machine Tool Works, Inc.
 Norton Company
 Potter & Johnston Machine Company
 Quickwork Company
 Reed-Prentice Company
 Starrett Company, The L. S.
 Warner & Swasey Company

The number of visitors at the exhibition demonstrated the interest which the English engineering industries displayed in it. It was very apparent that the visitors attended from no idle curiosity but for the purpose of learning how improved machine tools can be used advantageously in their work.

STEEL TREATERS MEET AT PHILADELPHIA

Two Steel Treating Societies Amalgamate and Hold Second Annual Convention and Exhibition

ONE of the most important steps toward a more widespread knowledge of the correct heat treatment of steel was taken at the Commercial Museum, Philadelphia, Pa., September 14, when the American Steel Treaters' Society and the Steel Treating Research Society united in a new organization known as the American Society for Steel

Cattell, city statistician, on behalf of Mayor Moore, who was unable to be present. Lt. Col. White responded to Mr. Cattell. Eight technical sessions were held and many important papers covering practically all phases of steel treating were read or presented by title. Some of these papers are of especial interest to railway shop men and will be abstracted

Lieut.-Col. A. E. White
President

T. E. Barker
First Vice-President

T. D. Lynch
Second Vice-President

W. H. Elsenman
Secretary

W. G. Bidle
Treasurer

Treating. The occasion for the union of the two societies was the second annual steel treaters' convention, lasting five days from September 14 to 18 inclusive. More than 250 members attended the opening session, which was presided over by Lt.-Col. A. E. White, chairman of the Amalgamation Committee. The total attendance for the week was 12,000

The convention was welcomed to Philadelphia by E. J.

in this and subsequent issues of the *Railway Mechanical Engineer*.

The exhibition of all kinds of heat treating equipment and many heat treated products including forgings, die blocks, castings, tool steel, etc., was exceptionally complete and interesting. Nearly 100 manufacturers were represented on the floor of the exhibition hall and much of the equipment

was shown in actual operation. Particular comment was made on the display of stainless steel cutlery and tools and the statement was made that American manufacturers may well hope to equal, if not surpass, the famous Sheffield steels manufactured in England.

At the conclusion of the technical sessions, numerous inspection trips to industrial plants and other points of interest were made. The annual banquet and entertainment was held Thursday night, September 16, in the grand ball-room of the Bellevue-Stratford. Following the banquet the members and guests were addressed by Dr. Albert Sauveur, professor of metallurgy, Harvard University, Dr. Joseph W. Richards, secretary of the American Electro-Chemical Society and Samuel M. Vauclain, president of the Baldwin Locomotive Works, Philadelphia.

A PROCESS FOR THE MANUFACTURE OF HELICAL SPRINGS FOR HEAVY DUTY

BY T. D. LYNCH

Research Engineer, Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.

Helical springs subjected to an unusually severe duty are shown in Fig. 1. They transmit the driving power of the motor to the wheels of a locomotive through gears and a set of cushion springs, the arrangement being such as to permit free vertical and lateral wheel play. In this application the stresses are tension, compression, torsion and shear, separately or in combination, and these stresses are augmented from time to time by shock, producing a condition that makes

Fig 1—Driving Arrangements on Electric Locomotive Wheel

necessary a material of high elastic strength, and, at the same time, a large degree of toughness. The common practice of spring making, using carbon steel, did not produce a sufficiently reliable spring and it was found necessary to use an alloy steel specifying not only its analysis but the entire process of manufacture and testing.

Manufacture of the Steel

The steel shall be made by the crucible or electric furnace process and have the following chemical analysis:

Carbon50-.60 per cent	Sulphur	Not over .04 per cent
Manganese60-.80 per cent	Silicon	1.90-2.20 per cent
Phosphorus	Not over .04 per cent		

The ingots shall be not less than 9 in. square at the large end and 8 in. square at smaller end, so poured and the molds so coated as to give a smooth surface to the ingot. Each ingot, when cold, shall be carefully inspected and any blemishes chipped or ground out, leaving a surface free from laps or seams after rolling. The ingots shall be slowly and

carefully heated to approximately 1,100 deg. C., rolled or forged to squares of approximately 3 in. by 3 in. and sheared into suitable billet lengths for final rolling. Excessive reduction will not be permitted. Sufficient discard shall be made so that no sign of piping or segregation can be found when careful inspection is made, especially of the top cut.

The billets shall be allowed to become cold and a very careful inspection made for surface defects and any slight blemishes ground out, leaving a smooth, even surface, no ragged corners or slivers being permitted. The billets shall then be heated to approximately 1,100 deg. C. and rolled to finish size, great care being taken to avoid excessive reduction at any one pass. The bars shall be sheared to length and carefully inspected for piping, segregation and surface defects. Each bar shall be straight, free from surface cracks, scratches, seams, folds and indentations and shall be true to section. The diameter of the bar shall not vary more than two and one-half per cent from that specified. All bars shall be tied in bundles and a metal tag securely attached to each bundle. This tag shall have stamped on it the requisition number, heat number, size of rod and manufacturer's identification mark. When bundles are opened, great care must be exercised not to nick or in any way injure the bars. A nick or scratch in a bar, however small, cannot be permitted.

Coiling of Springs

The bars shall be heated slowly to a uniform temperature of approximately 925 deg. C. and immediately coiled over a mandrel preheated to at least 100 deg. C. The mandrel shall not be water cooled, nor shall any water be allowed to touch the spring while hot. Notching for length shall be done at a dull red heat and in such a manner as not to cut, scratch or otherwise injure the surface at any other point on the spring. The springs after notching shall be allowed to cool slowly and uniformly in such a manner as to prevent local chilling, which may cause surface stresses or cracks to form.

The springs shall be slowly and uniformly preheated to approximately 700 deg. C., transferred to a furnace held at a quenching temperature of 900 deg. C. and uniformly heated as near as possible to this temperature and quenched in oil. The quenched spring shall be drawn in a salt bath at approximately 455 deg. C. to relieve quenching stresses. The drawn springs shall be cleaned from the adhering salt by a hot soda wash, followed by an oil or lime dip to protect them from corrosion.

Physical Properties and Tests

The properties specified below shall be determined in the order given and the spring shall not be rapped or otherwise disturbed during the test.

(a) The solid height is the perpendicular distance between the plates of the testing machine when the spring is compressed solid with a test load at least 125 per cent of that necessary to bring all the coils in contact. The solid height shall not vary more than 1.5 per cent from that specified.

(b) The free height is the height of the spring when the load specified in (a) has been released, and is determined by placing a straight-edge across the top of the spring and measuring the perpendicular distance from the plate on which the spring stands to the straight edge, at the approximate center of the spring. The free height shall not vary more than 1.5 per cent from that specified.

(c) The loaded height is the distance between the plates of the testing machine when the specified working load is applied. The loaded height shall not vary more than 1.5 per cent over, nor more than .70 per cent under, that specified.

(d) The permanent set is the difference, if any, between

the free height and the height (measured at the same point and in a similar manner) after the spring has been compressed solid three times in rapid succession with the test load specified in (a). The permanent set shall not exceed 4 per cent of the free height.

(e) The Brinell hardness number shall not be less than 375 nor more than 450. This test shall be made on the coupon resulting from notching to length and broken off after the spring has been heat treated.

(f) The grain structure of the finished spring should be troostitic or troosto-sorbitic.

Specifications as to dimensions, packing and inspection also were included in this paper, which was intended to emphasize the great importance of a better knowledge of complete spring manufacture and bring together on common terms the designing engineer, the steel maker and the spring maker.

THE FIELD FOR HEAT TREATED LOCOMOTIVE FORGINGS

BY J. C. MARSH

Metallurgist, Railway Mechanical Engineer

AND C. B. BECK

Associate Editor, Railway Mechanical Engineer

There is hardly a forged part entering into the construction of the locomotive which is not a fit subject for heat treatment in some form, and there are none of the operations covered by the general term "heat treatment" which have not already been employed to some extent either in the manufacture or maintenance of these parts. In considering the field for heat treatment of locomotive forgings a knowledge of the conditions of service to which these parts are subjected is quite necessary. The important parts to which the present discussion will be limited are the reciprocating parts, which include piston heads, piston rods, cross head pins and main rods, and connecting rods, crank pins, axles and valve motion parts.

In varying degree these parts are all subjected to shocks and constant repetitions of alternating stresses. In a table included in the progress report* of the Committee on Fatigue Phenomena in Metals, which is acting under the joint auspices of the Engineering Foundation and the Division of Engineering of the National Research Counsel, is given the approximate service required of various structural and machine parts subjected to repeated stresses. The approximate number of repetitions of stress in the life time of these parts varies from 2,000,000 for the members of railroad bridges to 15,000,000,000 for steam turbine shafts. Next to the highest figure shown is 1,000,000,000 for steam engine piston rods, connecting rods and crank shafts. Considering the life of the average locomotive, it is probable that the same parts of the locomotive should be able to withstand from 300,000,000 to 400,000,000 stress repetitions within the time they are in service. The life of airplane engine crank shafts is given as 18,000,000 stress repetitions and that of automobile engine crank shafts as 120,000,000. These figures are only approximate but they serve to show the comparatively severe limitations which are placed on refinements of the design of locomotive parts, in order that they may successfully withstand the severe shocks and heavy repeated loads to which they are subjected during a life time which is long as compared to that expected from similar parts in automobile or aeroplane engines.

Limitations Modified by Heat Treating

It is these limitations to refinements of design which heat treatment (the term now being used in its restricted sense of quenching and drawing) has offered some promise of modifying. The greatest need for such modification is in

connection with the reciprocating parts. Here the need for refinement permitting the use of lighter parts is measured not by the possible reduction in weight of the parts themselves but by the reduction of the destructive effect of the dynamic augment, that is, the vertically unbalanced centrifugal force produced by the excessive counter balance which must be placed in the driving wheels to take care of the horizontal effect of the reciprocating parts, which multiplies the effect of the weight involved by 36 to 40 times at the maximum speeds of the locomotive. Thus every pound by which the weight of reciprocating parts is reduced permits the addition of many times that amount of effective weight in some other part of the locomotive without any increase in destructive effect of the locomotive on track and bridges. The need, therefore, is for a material which may be subjected to higher working stresses alternating from a maximum load in tension to a maximum in compression (under the conditions of column loading). But owing to the large amount of clearance and wear which are permitted in locomotive bearings as compared with the bearings of other machines, each repetition of stress subjects the parts to severe shocks. No increase in working stress can, therefore, be permitted which decreases the ability of the material to withstand several hundred million of these shocks without failure.

The sizes of driving axles on modern locomotives, particularly those of the 2-10-2, or Santa Fe type, have increased to such proportions that they present a real problem in locomotive design. Sizes have increased until journals 12 in. and 13 in. in diameter are not uncommon and the difficulties from friction and wear, owing to the high peripheral speed of these large bearings, present a serious problem. Here, it is evident that the importance of being able to increase working stresses above those commonly used in the design of these parts is much greater than can be measured by the saving in weight to be effected on the locomotive as a whole. These axles in addition to the load on the bearings due to the weight of the machine, are subjected to constantly repeated combined torsion and bending stresses, each repetition involving shocks, increasing in severity as the bearings wear. The axles are also subjected to shocks from the lateral motion of the engine, acting against the rail through the wheel flanges, and from rail joints, frogs and crossings.

While the same need does not exist for reduction in the weights of crank pins as has been pointed out in the case of reciprocating parts and axles, there is no doubt but that full advantage would be taken in the design of these parts of any material offering the possibility of a higher working stress without a sacrifice of reliability. This statement probably applies with equal force to valve motion parts. The whole problem, therefore, in considering the possibilities for increasing working stresses in locomotive forged parts may be summarized as that of maintaining unimpaired the reliability of these parts to withstand fatigue stresses. Reliability—freedom from failures under sudden and severe shocks—is the first requirement for locomotive forgings; long life, the ability to resist fatigue, is the second requirement, and the third—a high working stress—must not be obtained at the sacrifice of either of the other two.

Factors of Safety

A general idea of the factors of safety considered necessary in the design of these parts may be obtained from the following table which shows the working stresses usually used in the calculations of sizes of critical sections:

Part	Working stress, lb. per sq. in.
Crank pins	17,000
Axles	23,000
Main rod stubs and straps	5,000-8,000
Piston rods	10,000

These stresses are based on carbon steel with a carbon content ranging between .38 per cent to .52 per cent with the

*See *Mechanical Engineering* for September, 1919, page 731.

following minimum physical requirements for the annealed forgings:

Tensile strength, lb. per sq. in.....	80,000
Yield point.....	.5 tens. str.
Elongation in 2 in., per cent.....	18-20

In locomotive parts, as in those of all machines, the yield point or elastic limit is of considerable importance. An increase in elastic limit is always a tempting factor, in that it offers a possible reduction of cross sectional area, and a corresponding reduction in the weight of the part. Ductility, however, is the counter balance. Endurance to alternating or vibratory stresses is presumably dependent on the difference between the yield point and the ultimate load, although it is by no means an infallible criterion. The railway mechanical engineer desires a high yield point and knows he must have a goodly percentage of elongation.

There is little difficulty in securing a considerable range of static physical characteristics by the application of heat treatment. A carbon steel with a carbon content near the lower limit of the above specifications may have its yield point raised nearly to the tensile strength of the annealed material by quenching and drawing, without reducing the elongation lower than the minimum specified. The range between the elastic limit and the ultimate load, however, is reduced, and in the case of carbon steel, grave doubts exist in the minds of some engineers as to the safety of taking advantage of these improved static properties of the material for any increase in allowable working stresses.

Another factor must be given serious consideration in connection with the employment of heat treating processes on locomotive forgings. The average conditions surrounding the maintenance of railroad motive power is such that any part, the normal working physical properties of which cannot be safely restored by the simple process of annealing, following possible repairs in the blacksmith shop, or which requires special care in machining to prevent the possibility for the development of dangerous local stresses, such as might result from rough lathe work on certain parts, has a restricted opportunity to show what it is worth. There is also an element of risk in its use, which violates the first requirement for locomotive material.

Alloy Steels

In view of the hesitancy to place full dependence on the raised yield point which may be obtained with carbon steel by suitable heat treatment, it seems evident that any extensive development toward possible increased working stresses must be largely with the alloyed steels.

With the carbon comparatively low, that is around 0.30 per cent, and the strength of the steel built up with such alloying elements as nickel, chromium, uranium, boron, copper and molybdenum, the results of heat treatment become more uniform, and an increase in ultimate strength and yield point can be obtained with less sacrifice of ductility and endurance. A slight gain in yield point may be obtained by quenching the steel and then drawing to a temperature nearly up to the quenching temperature. Some alloy steels can be heated to a point just below the critical temperature, quenched in oil and then drawn to a temperature about 400 deg. F., lower than the critical temperature, giving a yield point midway between those of the same steel in the annealed and the quenched states, with a percentage of elongation as high as the annealed steel or higher. Such steels, so heat treated, show a resistance to fatigue nearly equal to that of the annealed steel.

Other alloys have been developed which, when subjected to the simple process of annealing, produce a decided increase in ultimate load and elastic limit as compared with carbon steels of the same ductibility. Some of the vanadium steels are in this class. Such a steel having a carbon content of about .27 per cent, vanadium .17 per cent and chromium 1.0

per cent, annealed at 1,570 deg. F., develops an ultimate tensile strength of 96,000 lb., an elastic limit of 63,000 lb., with an elongation of 33 per cent in 2 in. and a reduction of area of 61 per cent. Plain carbon-vanadium steels having 20 points carbon, and .27 points vanadium, annealed at 1,475 deg. F., develop a tensile strength of 81,000 lb. and an elastic limit of 63,000 lb. with an elongation of 29.5 per cent and a reduction of area of 59.4 per cent.

Another alloy steel has recently been developed which possesses similar characteristics. This steel is a simple alloy of uranium and carbon. Tests of such a steel having a content of .12 per cent carbon and .15 per cent uranium, have shown a tensile strength of 52,000 lb., an elastic limit of 33,300 lb., a 40.5 per cent elongation and a reduction of area of 70.5 per cent after annealing. With a higher carbon content of .54 per cent and .29 per cent uranium, this steel developed a tensile strength of 101,690 lb., an elastic limit of 58,960 lb., a 23 per cent elongation and a reduction of area of 45.5 per cent.

There are a large number of steels which produce excellent results when subjected to the quenching and drawing process. Among these it may be well to mention the molybdenum steels, because of the comparatively wide temperature range within which they may be heated without detriment to their physical properties. Typical results of tests on 1 3/4-in. bars, heat treated full size, and machined to .505 in. in diameter, showed a hardening range from 1,400 deg. F., to 1,600 deg. F.; these test bars were quenched in water from 1,540 deg. F. The analysis is as follows:

Carbon26 per cent
Mg.60 per cent
Si.10 per cent
Cr.75 per cent
Ni.	1.96 per cent
Mo.56 per cent
Tensile strength	149,000 lb.
Elastic limit	120,000 lb.
Elongation in 2 in.	25 per cent
Reduction of area.....	68 per cent

Except for the longer life expected of the locomotive, the design of the automobile and motor truck involves much the same problems as the design of the working parts of the locomotive. The stresses to which automobile parts are subjected are quite as varying as those of locomotives. Impact stresses sustained by automobile axles are far greater in proportion to the cross section area of the axle than those to which locomotive axles are subjected. The automobile and truck axle has to resist alternating, vibratory, transverse and shock stresses. These axles are usually heat treated and their yield points are higher than those of locomotive axles per square inch of cross section area. Their dead load is comparable with that on the locomotive and their design is a factor against them as compared with those of a locomotive. Their percentage of failures is certainly not greater. The automotive field has about solved its problem by the use of heat treated alloy steels and the railways have not solved theirs at all.

Conclusions

The greatest obstacle to a rapid development in the use of heat treated locomotive parts is probably the conditions under which locomotives are maintained, together with the much greater importance of maintenance as a factor controlling the original construction in the case of the locomotive than that of the automobile. Railroad shops are seldom provided with facilities suitable for working materials which require the complicated heat treatment of pieces of large size, and practically all of the forged parts under consideration are passed through the blacksmith shop, either in the course of maintenance, or to be reclaimed for other use, in sufficient number, to make such equipment quite essential if results on a large scale are to be obtained.

The problem is by no means hopeless, but it seems evident that for the immediate future at least, the greatest possi-

bilities for development lie with alloy steels of the simplest composition, in which the greatest reliability, longest life and highest tensile strength can be developed by a simple heat treating process, not requiring too great a degree of precision.

As the effect of heat treatment on fatigue properties becomes less a matter of speculation, and the railroad world becomes better acquainted with the physical effects of the heat treating process the designer will undoubtedly be less loath to take advantage of the wider range of possibilities offered by the more complicated heat treating processes.

THE HARDENING OF HIGH SPEED STEEL

BY A. H. D'ARCAMBAL

Chief Metallurgist, Pratt & Whitney Company, Hartford, Conn.

The experiments referred to below were run primarily to determine the effects of various hardening methods on the hardness, microstructure and cutting efficiency of high speed steel. The best known brands of high speed steel made in

this country and abroad were selected for these tests, the analysis of the steels being shown in Table 1. As can be seen from this table eight of the brands were made by the crucible process, the other four being melted in the electric furnace. The majority of the analyses are of the eighteen,

Fig. 1—Scleroscope Curve, Steel No. 1, Heated to 2,300 Deg. F. in Open Fire and Quenched Into Oil at 100 Deg. F.; Drawn at Temperatures Indicated.

one, four type. Steels numbered seven and twelve were both supposed to be of the high vanadium lower tungsten analysis but the vanadium in number seven steel is much lower than the desired percentage. Bar number five is an analysis quite new to this country but better known abroad. Steel number six was selected to determine if cobalt present in an eighteen, one, four type of steel added to its cutting efficiency. The forged blanks, assigned number fourteen, were made from

bar number fifteen. Steels number five, eight and ten were made abroad. As it was decided to use four-inch cutters in this test, the bars were ordered four and one-fourth inches round. The Brinell hardness ran from two hundred and seventeen to two hundred and eighty-six, the only one giving trouble in machining being number five bar, but the trouble was not severe enough to make it necessary to re-anneal this steel.

Small discs were cut from some of the bars, thirteen of these being heated in the open fire furnace to 2,300 deg. F. and quenched into oil, thirteen heated in barium chloride at 2,100 deg. F. and oil quenched, and thirteen heated in a charcoal pack to about 2,050 deg. F. and oil quenched. These were then given various drawing temperatures up to 1,300 deg. F. and the scleroscope hardness taken, using a type D scleroscope (Dial recording type). The results plotted on six charts one of which is shown in Fig. 1 give the following information:

Conclusions from Scleroscope Curves

1. That the majority of brands of high speed steel when given a high quenching temperature (about 2,300 deg. F.) are just as hard or slightly harder after being drawn to 1,100-1,150 deg. F. as when quenched.
2. That 600-1,000 deg. F. is the softening range for hardened high speed steel.
3. When high speed steel is quenched from a lower temperature (2,000-2,100 deg. F.) almost the same initial scleroscope hardness is obtained as when quenched from a higher temperature, and the same characteristic curve is ob-

Fig. 2—Brinell Curve, Steel No. 1, Heated to 2,350 Deg. F. in Open Fire and Quenched Into Oil at 100 Deg. F., Brinelled at Temperatures Shown.

tained on drawing. The lower the quenching temperature, however, the lower the temperature at which the rehardening occurs on drawing and the greater the falling off in hardness after this point is passed.

Samples which had been quenched from 2,300 deg. F. and drawn to 1,100-1,150 deg. F. were redrawn to 600 deg. F. but did not change their scleroscope hardness. This shows that the scleroscope curve obtained on redrawing a piece of hardened high speed steel which had been drawn to 1,100 deg. F. would be a straight line, instead of showing a softening range from 600-1,000 deg. F. as is obtained on the original drawing of the sample hardened from a high heat.

In order to determine the hardness of hardened high-speed steels at temperatures from 400 deg. F. to 1,200 deg. F. temperature Brinell curves were obtained as follows: five-eighths inch thick discs were cut from the four and one-fourth inch round bars of high speed steel, and these were

cut in two. These discs were then hardened and brinelled cold. The method of hardening one disc is shown in Fig. 2. They were then heated in a small electric muffle furnace, two at a time, the pyrometer placed between the two discs and touching them. The pieces were held at the desired temperature for a sufficient length of time to insure thorough soaking, and then removed from the furnace, placed on a steel block of the same temperature, and rapidly brinelled. A new Brinell ball was used for each Brinell. These impressions were read immediately after brinelling and the discs again placed in the furnace for the next higher temperature. After the Brinell at 1,200 deg. F. was taken, the pieces were quenched and again brinelled. A temperature Brinell curve on a disc of carbon tool steel, properly quenched, was also obtained for comparison. A study of the Brinell curves showed the following:

Conclusions from Brinell Curves

1. The higher the quenching temperature the greater the hardness at temperatures from 600 deg. F. to 1,200 deg. F.
2. The cobalt molybdenum steel shows considerably lower temperatures, Brinell reading from 400 deg. F. to 900 deg. F. temperatures than do the tungsten steels.
3. High-speed steel quenched and drawn to 1,100 deg. F. shows a greater Brinell hardness at temperatures from 600 deg. F. to 900 deg. F. than when only drawn to 450 deg. F.
4. The temperature Brinell readings on the high-speed steel quenched from 2,300 deg. F. are all the same with one exception, at 1,100 deg. F.
5. Hardened high-speed steel, while not as high as carbon tool steel as quenched, is almost three times as hard at a lower red heat.

Cutter Tests

It was decided to use heat-treated chrome-nickel steel, similar to that used for crankshafts, connecting rods, etc., in aeroplanes and automobiles for testing these cutters. The one and five-eighths in. by two and one-half in. bars of this steel were all from the same electric furnace heat of steel, and all hardened exactly the same, giving a Brinell hardness of two hundred and sixty-nine to two hundred and seventy-seven. All sides of these bars were rough ground after hardening, removing the scale. Some of these cutters failed at the corners, others showed a uniform wearing down of the cutting edges. Table II shows the results of these tests and all figures given are the average of two cutters, making the final average in each case that of four cutters.

The cutter used was of the coarse tooth side milling type, 4 in. by $\frac{5}{8}$ in. by 1 in. hole. The material cut was slabs 16 in. by $2\frac{1}{2}$ in. by $1\frac{5}{8}$ in. with the following analysis: carbon, .46 per cent; manganese, .60 per cent; chromium, 1.16 per cent. The physical tests (standard .505 test piece) showed: elastic limit, 112,000 lb. per square in.; tensile strength, 126,000 lb. per square in.; elongation 20 per cent; reduction of area, 54 per cent; Brinell hardness, 269. The constants were: speed, 130 ft. per min.; feed, $3\frac{11}{16}$ in. per min.; depth of cut, $\frac{1}{8}$ in., and coolant, oil.

Steel number twelve, the high vanadium lower tungsten material, showed the highest cutting efficiency, the cobalt steel coming second. In every case, cutters given the 1,100 deg. F. draw showed a much greater cutting efficiency than with the 450 deg. F. draw. Cutters made from number five steel were given a quenching temperature higher than that recommended by the manufacturer, but it was decided to harden all of these cutters in exactly the same way. Cutters made from forged discs showed about twenty-five per cent greater efficiency than those machined from the same bar.

Cutters drawn to 800 deg. F. which is in the softening range, showed less efficiency than when drawn to 450 deg. F. Cutters quenched from 2,300 deg. F. into nitre at 1,100

deg. F. held there about four minutes, and oil quenched show about twice as much work as when quenched into oil and drawn to 450 deg. F., and a little more than half as much work as when given the 1,100 deg. F. draw. As

nitre at 1,100 deg. F. will attack high-speed steel quenched from a high temperature, a lead bath is recommended.

Precautions in Hardening High-Speed Tools

1. The tools should be thoroughly preheated, the use of two preheated furnaces being recommended, one maintained at a temperature of from 1,000 to 1,100 deg. F. and the other at a temperature from 1,500 to 1,700 deg. F.
2. The tools should be kept in the superheat only long enough for the material to come to the proper temperature. Soaking at high temperatures ruins the steel.
3. A careful selection of the quenching oil should be made as too rapid a quenching oil will cause cracks.
4. When drawing hardened high-speed steel to around 1,100 deg. F., the material should be brought up to the desired temperature with the bath, and never placed into the bath at 1,100 deg. F., as this will also produce cracks. The material should be held from ten to thirty minutes at the drawing temperature and air cooled or oil quenched.

THE FUTURE FUEL FOR THE TREATMENT OF STEEL

BY H. O. LOEBELL

Industrial Heating Dept., H. L. Doherty & Company, New York

This paper deals with the introduction, utilization and application of a fuel which will permanently solve the heating problem of industry. Important fuels of today are fuel oil, pulverized coal, and industrial manufactured gas. Fuel oil is a desirable fuel, but because of insufficient supply cannot be considered as the future fuel of our industry. Some

years ago fuel oil was selling at $2\frac{1}{2}$ cents per gal. and could be obtained in any desired quantity. Today it is selling at 12 cents to 15 cents per gal. and in many cases cannot be obtained at any price. This condition brings out the importance of considering the permanency of a fuel. Powdered coal is desirable in many cases but is only an intermediate development in the final solution of the problem. Ultimately our enormous coal resources will have to be treated in such a fashion that all the valuable materials from a ton of raw bituminous coal will be obtained.

Today, it is an established fact that the most flexible and efficient heating medium is a gaseous fuel. Bituminous coal resources are practically inexhaustible and therefore afford a raw material for the production of a fuel which will be permanent. From this coal we can make a gas which is very efficient and desirable and at the same time obtain all the valuable by-products that are in the coal. Such a fuel besides being permanent will never be prohibitive in price, as our methods of gas production, distribution, and utilization are always becoming more efficient and therefore the price of our gaseous fuel will have a tendency to decrease.

Advantages of Gas Furnaces

A flexible furnace design is one of the advantages in using gaseous fuel; also there are no ashes to bother with and no storage space required for the fuel. With a gaseous fuel, the most efficient combustion is obtained with the least amount of excess air. Also the temperature of a gas furnace is easily controlled and held within 10 to 15 deg. F.

If the merit of an industrial gas is judged by its B. T. U. value per cu. ft., manufactured coal gas of a 626 B. T. U. value would be the best, blue water gas with a B. T. U. of 300 second, and producer gas third. This, however, is not true. When a gas is burned, the heat developed is immediately utilized to heat the products of combustion of the burned gases. The burned gases give up their heat to the furnace walls and materials in the furnace, therefore the true source of the heat is the heat in a unit volume of the products of combustion. Also the flame temperature is directly proportional to the heat units in a cu. ft. of the burned gases. The more B. T. U.'s per cu. ft. of the products of combustion, the higher the flame temperature. This shows that not only are more heat units available, but there is a greater temperature differential between the flame and furnace material, and therefore a greater rate of heat transfer from the gas flame to the material in the furnace. Calculations based on this reasoning show that per cu. ft. of burned gas, blue water gas has both more heat content and greater heat intensity than any other industrial gas. This means greater heat transfer, greater production and higher efficiency.

The fact that a large number of producer gas plants are in existence is no argument against the use of blue water gas or any gas made from coal where all by-products are recovered. The producer gas plant is a part of the industrial institution of the past and only cheap and abundant fuel is justification for its use. One advantage of a gas producer is that a very wide range of fuels can be gasified. In fact, almost any kind of carbonaceous material can be converted into producer gas if it does not carry too much water or is not too greatly diluted with non-combustible material. The gas formed, however, may be difficult and uneconomical to use. Although producer gas is the cheapest gas which can be made per B. T. U. at the present time, its dilution with inert gas and its chemical characteristics greatly diminish its attractiveness as an industrial fuel.

Results of Furnace Tests

In order to show the advantages of a gaseous fuel and particularly a gas with a high flame temperature such as

blue water gas, the results of testing several installations, made during the past few years, may be cited. Under the best conditions of oil utilization it was found that $5\frac{1}{2}$ gallons of 142,000 B. T. U. oil can be replaced by 1,000 cu. ft. of a 600 B. T. U. manufactured gas. Under conditions where oil is used with efficiency, 14 gallons of 142,000 B. T. U. per gallon oil has been replaced by 1,000 ft. of 600 B. T. U. manufactured gas. Using coke and manufactured gas, a pound of coke has been replaced by 14 ft. of coke oven gas. At a large automobile plant working on high temperature forgings, 10 B. T. U. blue water gas has been substituted for 11 B. T. U. coke oven gas or 15 B. T. U. fuel oil. Thus, the possible efficiency of utilization of a fuel is directly proportional to its flame temperature and this fact coupled with actual comparative operating results proves conclusively that the most efficient fuel is one having a high flame temperature, such as blue water gas.

Another factor of essential importance in the heat treatment of steel is the formation of the scale of oxidation of the metal. Flue gases of any fuel contain varying amounts of water vapor, carbon dioxide, carbon monoxide, and nitrogen. When the fuel is burned with an excess of air, flue gases contain an appreciable amount of oxygen. This oxygen unites with the steel, forming an undesirable oxide or scale. In order to reduce the scale effect to a minimum, it is good practice to burn fuel with a slightly insufficient amount of air so that the flue gases contain a small percentage of carbon monoxide and no oxygen. Under these conditions far better results have been obtained with a high flame temperature gaseous fuel than with fuel oil. In 200 tests run during a period of several weeks in order to determine the relative values of fuel oil and blue water gas for high temperature forging the results were decidedly in favor of the gas as follows:

1. Increased production for gas over oil.....24.6 per cent
2. Fuel saving of gas over oil on basis of oil.....27.4 per cent
3. The gas furnace showed 36.6 per cent less scaling effect than the oil furnace.
4. The oil furnace had 800 per cent more burned forgings than the gas furnace.
5. Rejections were 50 per cent more on oil furnace forgings than on gas.

Summary

The ideal fuel for the heat treatment of steel must be of the following nature: (1) It must be permanent so that all future developments and furnace installations can be utilized for many years to the greatest possible extent; (2) it must have a high efficiency of utilization. It must be a fuel that will heat the metal with absolute uniformity in the minimum amount of time; (3) the effect of flue gases of the fuel in oxidizing the metal or scale forming must be reduced to a minimum; (4) such a fuel must be suited for our industrial operations and allied with the developments of all fuel resources so that standardized fuel can be produced at large central stations. This would mean enormous production, distribution and utilization; in other words, a cheap fuel. A fuel that approaches all the requirements of the ideal fuel is blue water gas.

RELATIVE ECONOMY OF OIL, GAS, COAL AND ELECTRIC HEATED FURNACES

BY W. H. LYMAN

Gen'l Sup't, Warner Gear Company, Muncie, Ind.

AND S. A. MOULTON

Industrial Furnace Corp., Boston, Mass.

The supply of natural gas has been seriously depleted in sections where it was formerly used and is an unreliable fuel. Owing to strikes of the coal miners and transportation difficulties, the cost of coal has increased greatly, and executives have viewed with alarm the magnitude of their fuel bill. Most serious of all is the fact that the demand for gasolene, kerosene and fuel oil has so far outstripped

the rate of oil production that its price has reached a point almost prohibitive. There is, in fact, a grave question as to the length of time that fuel oil can be secured at any price.

In view of the above serious situation, it is necessary to investigate all sources of heat supply. Table III gives a list of fuels and their respective heat values and cost:

TABLE III—HEATING VALUE AND COST OF FUEL

Fuels	Heating value in B. t. u.	Cost in Central West
Oil	140,000 per gal.	10 cents per gal.
Natural gas	1,100 per cu. ft.	50 cents per 1,000 cu. ft.
City gas	650 per cu. ft.	80 cents per 1,000 cu. ft.
Water gas	300 per cu. ft.	40 cents per 1,000 cu. ft.
Producer gas	170 per cu. ft.	10 cents per 1,000 cu. ft.
Coal	12,000 per lb.	\$6 per long ton
Electricity	3,412 per kwh.	1½ cents per kwh.

Temperatures up to 1,800 deg. F., may be obtained with any of the fuels in Table III, but for temperature over 1,800 deg. F., the producer gas and electricity require especially designed furnaces.

The figures shown in Table IV are based on actual tests and while certain assumptions had to be made and more or less empirical methods of deduction used, the results are substantiated by actual experience. In determining installation costs and fixed charges, the cost of installing oil and gas-fired furnaces was assumed to be \$100 per sq. ft. of hearth; coal fired furnaces, \$150 per sq. ft. of hearth; 100 kw. electric furnaces, \$90 per kw.; and 150 kw. electric furnaces, \$70 per kw. A charge of 3,000 lb. was assumed to require 8 hours' heat carburizing and 2 hours' heating. The total annual service was 7,200 hours. Fixed charges, including interest, depreciation, taxes, insurance and

9. Low cost of installation.
 10. Cleanliness of plant.
 11. Low fire risk.
 12. Continuous furnace practical.
 13. Low maintenance.
 14. Low labor cost.
 15. Minimum scale.
- Disadvantages—
1. High fuel cost.
- COAL (Can be used efficiently only for long heat service)—
- Advantages—
1. High efficiency.
 2. Low fuel cost.
 3. Life of container boxes longer than with oil.
 4. Total operating cost low.
 5. Reliability of fuel supply.
 6. Stability of fuel price.
- Disadvantages—
1. High initial cost.
 2. Repair of fire box due to high combustion temperature.
 3. Floor space occupied in coal and ash handling.
 4. Difficulty in keeping competent firemen.
- ELECTRICITY (Limited to temperatures below 2,000 deg. F.)—
- Advantages—
1. Absolute temperature control.
 2. No high combustion temperatures.
 3. Long life of furnaces.
 4. Simplicity of installation and operation.
 5. Elimination of piping mains, pumps or blowers.
 6. Automatic continuous equipment.
 7. High efficiency.
 8. Small floor space occupied.
 9. Flexibility.
 10. Cleanly plant conditions with consequent high morale.
 11. Quality of product.
 12. No damage to product.
 13. Minimum scale.
- Disadvantage—
1. High first cost.

Discussion of Table IV

Referring to Table IV, it will be noted that the fuel showing the greatest percentage of saving over oil in both heating and carburizing furnaces was natural gas, this favorable showing being accounted for by low fixed charges and low cost of heat. In carburizing furnaces, the fuel making the

TABLE IV—COMPARATIVE OPERATING COSTS WITH DIFFERENT FUELS

Class of fuel	Fuel per charge	Fuel cost	Installation cost	Efficiency per cent	Operating costs					Saving over oil	
					Fixed charges	Extra labor	Heat	Total per chg.	Cost per lb.	Per chg.	Per cent
Carburizing—	2	3	4	5	6	7	8	9	10	11	12
Oil	52 gals.	\$0.15	\$2,400	12.6	\$0.40	None	\$7.80	\$8.20	\$.00274	\$.620	76
Natural gas	4.4 M.	.50	2,400	18.8	.40	None	2.20	2.00	.00087	1.16	14
City gas	8.3 M.	.80	2,400	17.0	.40	None	6.64	7.04	.00235	.32	3.9
Water gas	18.7 M.	.40	2,400	16.4	.40	None	7.48	7.88	.00263	4.07	50
Producer gas	37.3 M.	.10	2,400	14.5	.40	None	3.73	4.13	.00137	3.95	48
Coal	914 lb.	6.00	3,600	8.4	.60	\$1.20	2.45	4.25	.00140	.80 loss	9.7 loss
Electricity	500 K.W.H.	.01½	9,000	53	1.50	None	7.50	9.00	.00300		
Heating—	30.8 gals.	.15	2,400	21.4	.10	None	4.62	4.72	.00157		
Oil	2.61 M.	.50	2,400	32.0	.10	None	1.30	1.40	.00047	3.32	70.5
Natural gas	4.9 M.	.80	2,400	28.8	.10	None	3.92	4.02	.00134	.70	14.8
City gas	11.1 M.	.40	2,400	27.6	.10	None	4.44	4.54	.00151	.18	3.8
Water gas	22.1 M.	.10	2,400	24.6	.10	None	2.21	2.35	.00078	2.41	51.1
Producer gas	486 lb.	6.00	3,600	15.75	.15	\$0.30	1.30	1.75	.00058	3.32	70.3
Coal	329 K.W.H.	.01½	10,500	81.75	.44	None	4.94	5.38	.00179	.32 loss	6.8 loss

maintenance were estimated at 15 per cent. Extra operating labor for coal fired furnaces was figured at 60 cents per hour with one man attending to 4 furnaces.

As a result of the tests, the following conclusions may be deduced as to the relative merits of different fuels:

Relative Merits of Fuels

- FUEL OIL—
- Advantages—
1. Low first cost for installation.
 2. Convenient fuel to handle.
 3. Simplicity of installation.
- Disadvantages—
1. High cost of fuel.
 2. Uncertainty of fuel supply.
 3. Difficulties of controlling temperature.
 4. Damage to product caused by 3.
 5. Inefficient combustion.
 6. Damage to furnaces from high temperatures when burned efficiently.
 7. Fire hazard.
 8. Continuous furnaces not practical except for large masses of metal.
 9. High labor cost due to 3, 5, 6 and 8.
 10. Short life of container boxes as compared with non-oxidizing gas fuel.
- CITY GAS (Especially adapted for high grade high temperature work)—
- Advantages—
1. High heat value.
 2. Small pipe main due to 1.
 3. Can be burned efficiently.
 4. Comparatively low temperature of combustion.
 5. Accurate temperature control.
 6. Uniform quality of product.
 7. Minimum damage to product.
 8. Simplicity of installation.

next most favorable showing was producer gas, also due to low fixed charges and low cost of heat. The cost of water gas was only slightly less than that for oil. Coal showed a considerable saving over oil due to its low cost and in spite of the fact that there was an extra labor charge. In both heating and carburizing, electric operated furnaces showed a loss as compared with oil furnaces.

Election of Officers

National officers of the American Society for Steel Treating were elected for the year 1920-21 as follows: President, Lt. Col. A. E. White, professor of chemical engineering, University of Michigan, Ann Arbor, Mich.; vice-president for two years, T. E. Barker, production engineer, Michle Printing Press & Manufacturing Co., Chicago; vice-president for one year, T. D. Lynch, research engineer, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.; secretary for two years, W. H. Eisenman, 208 N. Wabash Ave., Chicago; treasurer for one year, W. S. Bidle, president W. S. Bidle Co., Cleveland, Ohio; directors for two years, H. J. Stagg, asst. manager, Halcomb Steel Co., Syracuse, N. Y., and E. J. Janitzky, metallurgist, Illinois Steel Co., South Chicago; directors for one year, F. P. Fahy, New York, and W. C. Peterson, metallurgist, Packard Motor Co., Detroit.

EXAMPLE OF CORRECT TURRET LATHE PRACTICE

A Description of the First Operations Involved in Machining a Small Clutch Gear on a Turret Lathe

BY F. S. HARMER

RAILWAY machine shop operation can be much improved and the output increased by a more general use of turret lathes. Not only are these machines adapted to a wide variety of machine operations, but when properly set up, the amount of work that can be turned out will result in a considerable increase in machine shop output. When machining jobs within fine limits of accuracy,

the $7\frac{1}{4}$ -in. outside diameter, drilling and boring the larger recesses, facing the same and forming the chamfer. The piece is held in a 15-in. Coventry concentric chuck with special taper jaws for gripping the small diameter and is located with a set screw in each jaw to insure the piece be-

Fig. 1—Outline of Tool Set Up on Combination Turret Lathe

care must be taken in the method of machining to avoid distortion. The combination turret lathe is adaptable in this respect because of the great scope in the lay-out of the tools which makes possible a proper tool set-up to prevent undue strain of relieving in the finishing operations. The clutch gear, illustrated in Fig. 2, is made of a 70-point carbon steel forging and has some heavy counter-boring cuts, the limits in the 6-in. and 85 mm. diameter bores being within .001 in. The face setting on this piece consists of turning

Tool Set Up 9; Finish Reaming 6 In. Diameter

ing chucked in the correct position relative to the stops on the machine.

Referring to Fig. 1, the forging is first drilled through with the inserted bit *r*. Drills of this type are very economical, especially in drilling long holes, as they have no tendency to bind. They consist of a mild steel shank with an inserted high speed steel bit. When breakage occurs or the

bit is ground away so far as to be of little use, the cost of replacement is much less than the cost of a twist drill of the same diameter. The next operation is counter-boring the 85 mm. diameter. This is done with the counter-boring cutter, 2, which is steadied by a roll on the front of the bar. The cutter used is double ended and removes an equal amount

tools consist of a boring bar with cutter for boring 85 mm. diameter and a tool in the holder clamped to the bar for boring the 6-in. diameter all held in a turning tool holder over the face of the turret. The tool for turning the external diameter is held in a fine adjustment tool holder, thus insuring quick and accurate setting. The boring tools are also adjustable by screws operating underneath them.

The two recesses are next faced and the 6-in. diameter undercut with the tools shown in tool set up 6 on the square turret. The chamfer is finished and also the front face with tool 7 inverted in the holder on the back of the cross slide. This eliminates a great deal of chatter, which

Fig. 2—Dotted Lines Indicate First Operations on Clutch Gear

of metal on either side, thus tending to steady the cutting action of the tool.

The next operation 4, consists of counter-boring the 6-in. diameter, rough turning the 7 1/4-in. external diameter and rough forming the chamfer. In this operation, the counter-

Tool Set Up 5; Finish Boring and Turning Operations

boring cutter alone is removing 1 5/16-in. of metal on each side and at the same time, tool 3 is taking a rough facing cut. With the conclusion of the heavy roughing cuts the first finishing operation is to turn the 7 1/4-in. external diameter and bore the 85 mm. and 6-in. diameter, leaving about .007 in. for reaming with tool set up 5. These

Tool Set Up 6; Recess and Undercutting Operation

is liable to occur on broad chamfers when machining from the front tool post.

The 85 mm. and 6-in. bores are finish reamed with floating cutters, 8 and 9, each of these reamers consisting of two high-speed cutters floating in a slot in a steel holder. They have adjusting screws which enable the cutters to be kept up in size and are held in position by two flister head screws locating against a step in the back of the cutters. The heads of the screws have a flat milled way across them and when the cutters require regrinding, the screws are turned until the flat part clears the step in the cutters, which are then withdrawn. This method helps to make the regrinding a very quick operation.

All boring tools are equipped with an oil feed from the turret giving a direct supply of lubricant to the point of cutting, thus insuring the maximum cooling and also lengthening the life of the tools.

ROTATABLE COAL HOPPER FOR LOCOMOTIVES.—Firemen on big locomotives find promise of lightened work in the rotatable coal hopper that has been invented for engine tenders. This invention is so planned that the coal is kept handy at the firing deck, making it an easy matter for the firemen to reach the coal without shoveling from the rear of the tender or using power apparatus. This special hopper is in the form of a great segmental tub, or drum, having a diameter that is the approximate width of the tender. This drum is inclined toward the firing deck; it is so mounted on a ball-bearing center plate as to turn readily. In its outer wall are openings, one for each segment, through which the coal falls by gravity. As soon as the coal is emptied from the segment, the brake that controls the drum is released. Naturally the greater weight above the center of the drum makes it rotate, bringing the next loaded segment into position.—*Scientific American.*

Quick Opening Door in Front End Netting

A FRONT end netting door, which may quickly be removed and replaced and which has sufficient area of opening to facilitate thorough and rapid inspection of the spark arrester and draft appliances, is shown in the illustrations. This device was developed and patented by John Herron, general foreman, Duluth, South Shore & Atlantic, Marquette, Mich., and the patents are controlled by Mr. Herron and John A. Higgins, Manistee, Mich. The features

ing the vertical flanges at these points and completing the structure by welding. The door and frame angles are then fitted with countersunk bolts and the netting secured in place by the application of washers and nuts. The relative sizes of the door and frame are such that the door itself fits inside of the frame with an easy working fit. The door is held in place by retaining angles riveted to the top and bottom of the door frame, the vertical flanges of which extend up or down, as the case may be, in front of the door when it is placed in the frame.

Aside from the retaining angles which prevent the door from being removed without raising it in the frame, it is also

The Door Applied to a Mudge-Slater Spark Arrester

of this device which are of especial interest are the size of the door opening, the fact that it is locked in place by the use of one cotter key and the simplicity and rigidity of the door and door frame.

By referring to the drawing it will be seen that the entire device is built up of angle sections, the door itself being of $\frac{1}{2}$ -in. by $\frac{1}{2}$ -in. section, while the door frame is of $1\frac{3}{4}$ -in. by $1\frac{3}{4}$ -in. section. Both are built up by cutting 90-degree V-notches in the horizontal flanges of the angles at points corresponding to the corners, then forming the frames by bend-

Details of the Herron Spark Arrester

secured by a simple fastener which is locked by the use of a single cotter key in a $\frac{3}{8}$ -in. hole. This fastener, which is shown in detail in the drawing, consists of two parts, one of which is riveted to the bottom of the door. A movable piece is pivoted to the fixed piece in such a way that when it is latched under the door frame it lies under the fixed piece, to which it is immovably secured by the use of a cotter key. To unlock the door the key is removed and the movable piece turned parallel to the face of the netting, when the door may be raised and removed from the frame.

This door has been in use on a large number of the locomotives of the Duluth, South Shore & Atlantic since 1917 and is also being applied to a number of locomotives on other railroads. In many localities where there is serious danger of fires from locomotive sparks during the dry season, inspection of the spark arrester is required as frequently as once in 24 hrs. Under such conditions the convenience of a quick opening netting door of large area is apparent.

Sibley Stationary Head Drilling Machine

A NEW stationary head drilling machine built in 24 in., 26 in. and 28 in. sizes has been placed on the market recently by the Sibley Machine Company, South Bend, Ind. This machine is provided with positive geared feed, back gears and in general is modeled after the sliding head drilling machine described on page 173 of the March, 1920, *Railway Mechanical Engineer*.

Designed to meet modern production requirements, the machine is strongly made with a base which is well ribbed and braced, with tee slots provided for clamping work.

Increased length of bearings on the head and arm and a substantial table support give additional strength and accuracy. The speeds and feeds are selective and have a wide range. The spindle is balanced by a weight supported inside the column with a Diamond chain operating over large diameter sheaves. The safety of the operator is assured by enclosing the gears.

A positive geared tapping attachment, geared or belted motor drive, round or square table, with oil pump or a quarter-turn countershaft can be furnished as special equipment.

Staybolt Cutter Adapted for Riveting

THE staybolt cutter, manufactured by the Baird Pneumatic Tool Company, Kansas City, has been adapted for riveting purposes by certain alterations shown in the illustration. This makes a double purpose tool and one which has another distinct advantage, namely: adaptability for close corner work. The tool is constructed along the same principles as the regular line produced by the Baird Company, but special arms and dies enable work to be performed in extremely close corners. Fifty tons pressure exerted on the dies enables 5/16 in. rivets to be driven cold. This tool can be used to good advantage in many places which would be practically inaccessible to a hand hammer and rivets can be more uniformly driven than by hand.

The machine is composed of a 15 in. air cylinder, the piston head of which connects directly through a powerful toggle movement with a pair of lever arms. The removable riveting dies are securely fastened in the lever arms. On account of light construction and conveniently placed control valves, the machine can be operated by one man.

Fifty Tons Pressure is Exerted on Riveting Dies

Safety Valve for Pneumatic Motors

A PNEUMATIC safety valve combining simplicity, strength and durability, has been placed on the market by the Pneumatic Safety Valve Company, Woonsocket, R. I. This valve is designed to prevent acci-

dent to machine operators, increase production and reduce the injury and breakage of cutting tools, such as drills, reamers, taps, etc. It is made in one size only for Nos. 1, 2, 3 and 4 non-reversible rotary machines and its use does not necessitate any extensions, alterations or change from present equipment.

In operation the valve is attached directly to the machine in place of the customary air control handle. The air hose is then attached to a specially constructed handle furnished with each valve, and the machine operated in the usual way. The valve consists of a body *A*, control valve *B* and cap nut *C* for regulating the pressure. If the air pressure is at 85 lb., the cap nut can be turned down, thereby tightening the spring tension of the valve until air passes freely to the machine. When the cutting tool jams or binds by reason of abnormal resistance, a back pressure is instantly created within the valve chamber which closes the valve, shutting off the air and preventing the kick of the machine, which usually causes injury or damage. When the valve closes it cannot open and the machine cannot resume action until the operator closes the air control valve, which operation releases the valve to its normal position and opens the air line to resume work.

Safety Valve Applied to Motor

dent to machine operators, increase production and reduce the injury and breakage of cutting tools, such as drills, reamers, taps, etc. It is made in one size only for Nos. 1,

The pneumatic safety valve is made of standard design, all parts being interchangeable and can be taken apart, cleaned, oiled and reassembled in approximately three minutes. It is stated that this valve has been used in summer or winter with dependable results and withstood severe tests under all working conditions. Many accidents should be obviated by its use.

Cutting Lubricant System for Boring Machine

AN efficient and complete cutting lubricant system has been applied to the horizontal boring machine manufactured by the Universal Boring Machine Company, Hudson, Mass. This addition is in line with the recent tendency of modern machine tool manufacturers to increase the production of their machines to the maximum by furnishing an abundant supply of cutting compounds or lubricant to the cutting tool. Heat must be carried away from the cutting edge of the tool where the work is being done and for this purpose it is better to supply too much rather than too little compound.

In order to supply an adequate amount of cooling compound, an impeller type pump *A* with a capacity of 12 gal. per min. is attached to the motor bracket and driven by a belt upon the motor shaft. The reservoir or tank *T* holds the excess compound which flows to the pump through an intake pipe *A*. It is stated that the impeller type pump cannot lose its prime and that chips cannot stick and clog the system because anything that enters *A* can pass through the pump and all pipes. This avoids the necessity for strainers. The impeller pump by centrifugal force sends the compound through the delivery pipe *B*, various fittings, pipes and flexible tubes *C* and *D* to the cutting edge of the tool. The flow of compound is controlled by a valve shown.

The table has oil pockets *E* and *F*, at each end connected by grooves and from oil pocket *F*, the cutting compound is delivered to tank *T* by a flexible tube *G* of ample diameter. The machine bed has oil troughs on the front and back sloping towards the center. The front trough is on a higher level than the rear and lubricant is carried from the front to the rear trough by means of a 1 3/4-in. pipe. The lubricant accumulates in the rear trough and passes to the tank through

overflow pipe *H*. The flexible tube *D* facilitates the flow of the compound in any direction desired. The cutting lubri-

Universal Boring Machine With New Cutting Lubricant System

cant system described is applied to universal boring machines only on special order.

K & N Automatic Cylinder Cock

THE automatic cylinder cock, illustrated, is simple in construction and operation, being actuated by the difference in specific gravity of steam and water, and is reported to have given satisfactory results in regular daily service for more than ten months. Cylinder cocks of this type are screwed into the cylinders in the same places previously occupied by the old style cocks. No change is required except the elimination of the train of connecting rods and levers from the cab to the cocks.

Referring to the illustration, the central valve is kept from its seat by a spring when not subjected to steam pressure. This permits unobstructed passage for water, from the cylinders to the atmosphere. When steam is turned into the pipes it forces any water which may be there ahead of it to the cylinder cocks, which remain open. The water, because of its greater weight, will not follow the same path as the steam but flows out over the valve seat in the direction *A* indicated by the arrows. When the water has drained and been blown out it leaves an unobstructed passageway for steam, which because of its greater speed and less weight follows the other path *B* shown by the arrow, bringing it in a jet against the upper face of the inclined ring mounted on the valve. The jet of steam closes the valve against the action of the spring and the interior chamber fills with dry steam which fills the cylinder where the piston travels and exerts a downward pressure on the piston. This makes the downward pressure greater than the upward pressure plus the force of the spring. The cock is kept closed as long as steam pressure is on it, but when condensation occurs, the accumulated water will shut off the admission of live steam; the valve opens due to decreased pressure, and the conden-

sation is blown out. The same process is repeated as steam is allowed to enter the valve chamber again.

The above action eliminates the necessity of blowing out

Cylinder Cock Which Operates Without Levers or Connecting Rods

the cylinder cocks when starting and making the disagreeable alternating hissing sound which is so familiar and

annoying. The valve remaining open precludes the possibility of freezing up in winter and the starting of engines due to leaking throttle valve. It has been proved by test

that the central valve does not hammer its seat. Patents for the K & N automatic cylinder cock have been applied for by W. F. Koon and C. R. Nordberg, Duncansville, Pa.

Utility Screw Press a Handy Device

ONE of the handiest tools in a shop is a screw press. The Utility screw press illustrated can be used to straighten shafts, bars, rails, beams, etc. It is also arranged to press in or out bushings; press gears or wheels on and off shafts; and form or bend metal in many shapes. It is made by Carl Pletz & Sons, Cincinnati, Ohio.

The bed is 4 ft. long, deep and heavily ribbed with a hole cored under the screw to permit work to drop through to the floor when pressed out. These cored holes permit the pressing of pieces on or off long shafts. The two upright posts are more than strong enough to withstand any load that can be applied with the screw. A pad fits on the end of the screw and the thrust is taken on a hardened steel and bronze washer which sets in oil. The hand wheel on the end of the screw is fitted with a handle so that the screw can be returned quickly. By using a 4-ft. bar in the hand wheel, a pressure of 20 to 25 tons can be secured.

This press is made in two sizes, No. 3 and No. 3½, each being provided with a 2 in. screw with ¼ in. pitch. The No. 3 press measures 12¾ in. between posts and 14 in. under the screw pad, the overall length being 4 ft. and the height from the screw down 42 in. The No. 3½ measures 17¼ in. between the posts and 20 in. under the screw pad. The overall length is 4 ft. and height from the screw down 48 in. The presses weigh 700 lb. and 800 lb. respectively.

Utility Screw Press for Shop Work

Safety Wrench for Opening Car Hoppers

IN releasing the drop doors of freight cars, there is often considerable danger of personal injury. When the latch holding the door is released, the load comes on the operating wrench and it may be torn from the grasp of

Pa. This device, which is known as the "Swaco" safety hopper car wrench, allows quick manipulation with assurance of safety.

The mechanism of the wrench is so arranged that the top pawl is automatically thrown to the safety position when the wrench is lowered. Referring to the drawing, the operations in releasing the shaft to open the door are as follows: The spring lever, *A*, is thrown up as shown in Fig. 1, to force the top pawl *1* out of engagement with the ratchet. The wrench is then placed on the hopper shaft. By placing a finger at *B*, the pawl *1* is pressed down to engage with the ratchet. The operator then pulls up on the wrench handle to take the load off the pawl on the door frame which is lifted out of engagement, leaving the load on the wrench. By quickly lowering the wrench handle, pawl *1* is freed from the ratchet, the load rotating the ratchet in the direction shown. Should the door stick, the shaft can be revolved by pushing down on the wrench. To close the door, the spring lever, *A*, is reversed as shown in Fig. 4 to throw pawl *2* out and pawl *1* into engagement.

The "Swaco" hopper car wrench has a ball bearing head and the entire wrench is made from electric steel castings of high tensile strength. The socket is designed for holding 2 in. square shafts and bushings or reducing sockets are used to fit smaller sizes. This device is being used by railroads and also by many industrial firms.

Ratchet Mechanism of the Swaco Wrench

the man using it. To avoid the possibility of accident from this cause, a special type of ratchet wrench is now being made by the Safety Wrench & Appliance Co., Philadelphia.

THE AMERICAN WELDING SOCIETY has authorized the organization of a new section of the society in Cleveland. Preliminary steps have been taken and a meeting will be held shortly to effect an organization.

The Southern Pacific is planning to enlarge and improve its car shops in Sacramento, Cal. New buildings will be provided for the foundries, rolling mills and general shops.

The Southern Railway has put in service 1,093 freight cars since March 1, when the railways were returned to their owners; and new cars are being completed at the rate of eight cars a day. This equipment consists of 555 new steel underframe box cars and 538 steel frame coal cars, rebuilt from bad-order cars which were totally unfit for service and past the stage for economical repair.

A technical adviser from the United States has just completed a tour of inspection in connection with a large scale electrification scheme for the Austrian State Railways, according to the Scientific American. He commends the policy of the Austrian government in developing water resources to provide the necessary power and the decision to commence the work of railway electrification by converting the mountainous route to electric traction. He makes the definite statement that the electrification of the lines from the Swiss frontier to Innsbruck will save 150,000 tons of coal a year.

Chief Interchange Inspectors' and Car Foremen's Convention

The Chief Interchange Car Inspectors' and Car Foremen's Association held its twentieth annual convention at the Windsor Hotel, Montreal, P. Q., September 14-16. At the session on Tuesday morning, the convention was opened with prayer and an address of welcome was delivered by Alderman J. P. Dixon representing Mayor Martin of Montreal. T. J. O'Donnell responded to Alderman Dixon's remarks on behalf of the association. In the presidential address which followed, J. J. Gainey emphasized the benefits derived from the activities of the association in advancing knowledge regarding car construction and maintenance and promoting a uniform understanding of the A. R. A. rules and interchange matters in general. At this session there was also presented a paper on Transfers and Adjustments of Lading under the A. R. A. rules for Mechanical Defects, by J. M. Gitzen.

The meeting on Tuesday afternoon was devoted to a discussion of the A. R. A. Rules of Interchange with particular attention to the changes adopted at the June convention. This discussion was continued on Wednesday morning and at the conclusion a paper on the Transportation of Explosives was read by J. E. Grant of the Bureau of Explosives. An address on the same subject was given by J. O. O'Donnell, also representing the bureau. The influence of the work of the car department on the elimination of loss and damage to

freight was discussed by E. Arnold, freight claim agent of the Grand Trunk.

Two papers were presented at the meeting on Wednesday afternoon, the first on the Lubrication of Freight and Passenger Equipment by M. J. O'Connor; the second on the Best Methods of Repairing Cars in Train Yards by O. E. Sitterly. An interesting feature of this session was the showing of moving pictures illustrating proper and improper practices in designing and maintaining brake beams and brake shoes, prepared by the Chicago Railway Equipment Company. The meeting on Thursday was devoted to the reports of committees, the election of officers and miscellaneous business.

The officers chosen for the year 1920-1921 are as follows: President, E. Pendleton, C. & A.; first vice-president, A. Armstrong, Atlanta, Ga.; second vice-president, W. F. Westall, N. Y. C.; secretary-treasurer, W. P. Elliott, T. R. R. A. of St. L. Members of the executive committee: W. H. Sherman, Grand Trunk, and A. Herbster, N. Y. C. A complete convention report will be published in the November issue.

The Railroad Administration Settling Claims

The Railroad Administration has reached a settlement in the cases of approximately 2,000 claims filed by railroad companies on account of items of additions and betterments made during the period of federal control which the companies claimed were made for war purposes or in connection with unification and, therefore, were properly chargeable to the government rather than to the companies. The greater part of the claims have been rejected, although payments were agreed upon by the Railroad Administration amounting to approximately \$217,000. The claims which it has rejected or which were withdrawn during the negotiations amounted to approximately \$2,000,000. The Railroad Administration has now received complete claims covering all items of account between the companies and the Railroad Administration from 43 companies.

Lehigh Valley Employee-Stockholders

More than 1,000 employees of the Lehigh Valley have purchased stock in the company and additional subscriptions are being received daily. Recently employees were advised that they might become part owners of the railroad for which they work through the purchase of stock which could be paid for on the installment plan through small monthly deductions from the payroll, as was done during the several Liberty Loan campaigns. The company buys the stock on orders from employees and they pay the price prevailing at the New York Stock Exchange on the day their orders are

received. No drive was made, President E. E. Loomis having ordered that employees were not to be urged to purchase stock, but the first 1,000 purchasers have taken an average of 4.4 shares apiece, representing an investment of approximately \$200,000 at the present value of the stock. All classes of employees are represented among the purchasers, many using a part of the back pay recently received.

ALL LOCOMOTIVES ON THE M. K. & T. TEXAS LINES TO BE OIL BURNERS

Estimates compiled by the Missouri, Kansas & Texas as to the cost of operating oil-burning locomotives showed that they are more economical than those using coal, to the extent that the road is spending more than \$700,000 to convert all of the 315 locomotives operating on its Texas lines to burn oil fuel. This is a statement of one of the officers of the road published in the daily press. It is expected that the transformation will be completed by January, 1921. About 160 oil-burning locomotives, both passenger and freight, are now in use on the Texas lines of the Missouri, Kansas & Texas. The cost of converting one locomotive from coal to oil burning is stated to be about \$1,600. The installation of oil stations and storage tanks to serve the locomotives has been practically completed, at a cost of approximately \$200,000, an oil station having been installed at practically every place where a coal filling station was located.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III—MECHANICAL.—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- SECTION III.—EQUIPMENT PAINTING DIVISION.—V. R. Hawthorne, Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.—J. P. Murphy, N. Y. C., Collinwood, Ohio.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.—C. B. Baker, Terminal Railroad, St. Louis, Mo.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.—R. D. Fletcher, 1145 E. Marquette Road, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN SOCIETY FOR STEEL TREATING.—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.—Joseph A. Andreucetti, C. & N. W., Room 411 C. & N. W. Station, Chicago.
- CANADIAN RAILWAY CLUB.—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting October 12, Paper on Inventions for Patents will be presented by W. P. McTeat, Patent Solicitor, 83 Craig St., West, Montreal.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.—Aaron Kline, 626 N. Pine Ave., Chicago. Meeting second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.—Thomas B. Koenke, secretary Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.—H. D. Vought, 95 Liberty St., New York. Meetings second Friday in January, March, May and September, and second Thursday in November, Hotel Statler, Buffalo, N. Y.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.—W. P. Elliott, T. R. R. A., St. Louis.
- CINCINNATI RAILWAY CLUB.—H. Boutet, 101 Carew Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November.
- DIXIE AIR BRAKE CLUB.—E. F. O'Connor, 10 West Grace St., Richmond, Va. Next meeting November 8-9, Atkin Hotel, Knoxville, Tenn.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.—W. J. Mayer, Michigan Central, Detroit, Mich.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.—J. G. Crawford, 702 East 51st St., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
- MASTER BOILERMAKERS' ASSOCIATION.—Harry D. Vought, 95 Liberty St., New York.
- NEW ENGLAND RAILROAD CLUB.—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting October 12. Paper on What the Recent Freight and Passenger Rate Increases Mean to the Public will be presented by Garritt Fort, B. & M.
- NEW YORK RAILROAD CLUB.—H. D. Vought, 95 Liberty St., New York. Next meeting October 15. Paper on The Human Element in Railroad-riding will be presented by W. S. Wollner.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.—W. S. Wollner, 64 Pine St., San Francisco, Cal. Next meeting October 7. Ten-minute talks on More Transportation by railroad men and shippers.
- RAILWAY CLUB OF PITTSBURGH.—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Friday in month, except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.—J. B. Frauenthal, Union Station, St. Louis, Mo. Next meeting October 8. Paper on Industrial Conditions will be presented by R. D. Sangster, Industrial Commissioner, St. Louis Chamber of Commerce.
- TRAVELING ENGINEERS' ASSOCIATION.—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y.
- WESTERN RAILWAY CLUB.—Bruce V. Crandall, Chicago. Next meeting October 18.

PERSONAL MENTION

GENERAL

R. M. BROWN has been appointed engineer of motive power of the New York Central, with headquarters at New York. The position of engineer of motive power and equipment has been abolished.

CHARLES H. HOGAN, who has been appointed manager, department of shop labor of the New York Central, with headquarters at Buffalo, N. Y., as noted in the August *Railway Mechanical Engineer*, served as assistant superintendent of motive power of the first district, with headquarters at Albany, N. Y., previous to this promotion. Mr. Hogan was born in Cleveland, Ohio, on January 9, 1850. He received a public school education and began railroad work as a track worker for the New York Central on April 1, 1865. From 1867 to 1871 he served the Union Pacific, first as fireman and later as engineer. He then returned to the New York Central as locomotive engineer and filled that position until 1893, when he was appointed traveling engineer. In 1900 he was promoted to master mechanic and in May, 1904, he became division superintendent of motive power, with headquarters at Depew, N. Y. On August 1, 1910, he was appointed assistant superintendent of motive power at Albany, as mentioned above.

C. H. Hogan

HENRY WANAMAKER, who has been appointed district superintendent of motive power of the New York Central, with headquarters at Albany, N. Y., as noted in the August *Railway Mechanical Engineer*, served as superintendent of shops previous to this promotion. Mr. Wanamaker was born on August 5, 1866, at Pottsville, Pa. He received a high school education and began railroad work on August 1, 1884, with the Philadelphia & Reading, as a machinist apprentice. He was promoted to machinist in 1888 and served in that capacity until 1896, when he was appointed gang foreman at Reading, Pa. He left the Philadelphia & Reading in 1900 to become a foreman in the erecting shops of the New York Central at West Albany, N. Y., where he remained until 1905, when he was transferred to Depew, N. Y., as general foreman. In December, 1911, he was appointed superintendent of shops, with the same headquarters, and was transferred to West Albany on May 20, 1912.

H. Wanamaker

G. E. DOKE, engineer of materials of the New York Central, with headquarters at Collinwood, Ohio, has been appointed engineer of tests, with headquarters in New York.

A. H. EAGER, mechanical superintendent of the Canadian National, with headquarters at Winnipeg, Man., has been given jurisdiction over the lines of the Grand Trunk Pacific, in addition to his former duties. He will retain his former headquarters.

F. S. GALLAGHER has been appointed engineer of rolling stock of the New York Central, with headquarters at New York.

R. D. HAWKINS, equipment engineer of the Great Northern, with headquarters at St. Paul, Minn., has been appointed general superintendent of motive power of the Atlantic Coast Line, with headquarters at Wilmington, N. C. WILLARD KELLS has been appointed superintendent of motive power, with the same headquarters.

LAIRD W. HENDRICKS has been appointed mechanical superintendent of the Bangor & Aroostook, with headquarters at Bangor, Me., succeeding H. SHOEMAKER.

F. A. LINDERMAN, district superintendent of motive power of the New York Central, with headquarters at Oswego, N. Y., has been made division superintendent of motive power.

S. J. LUPTON, chief boiler inspector of the Canadian National, with headquarters at Winnipeg, Man., has been given jurisdiction, also, over the lines of the Grand Trunk Pacific.

S. WATSON has been made division superintendent of motive power of the New York Central at Avis, Pa., the office of district superintendent of motive power having been abolished.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

C. L. BUNCH has been appointed master mechanic of the Southern Railway at Meridian, Miss., succeeding H. M. Little, who has resigned.

H. E. DYKE has been appointed master mechanic of the Southern Railway at Sheffield, Ala., succeeding C. L. Bunch.

ALBERT G. HENTZ, whose appointment as master mechanic of the Harlem and Putnam divisions of the New York Central, with headquarters at West Albany, N. Y., was announced in the

A. G. Hentz

August issue, was born on May 20, 1889, at West Medford, Mass. He received the degree of mechanical engineer at Harvard University in 1909 and entered the employ of the New York Central on July 16, 1909, as a special apprentice at Avis, Pa. From July 1, 1911, until October 1, 1911, he served as a special engineer. He then became assistant engine-house foreman and acted in that capacity until October 1, 1912, when he was made erecting shop foreman. On July 1, 1916, he was transferred to New York city as a

traveling inspector for the equipment engineering department and on July 8, 1918, was promoted to assistant master mechanic of the Mohawk division. He held that position until July 1, 1920, when his recent appointment became effective.

E. L. NOTLEY has been appointed division master mechanic of the Chicago, Milwaukee & St. Paul, with headquarters at Perry, Ia., succeeding C. L. Emerson.

JESSE E. STONE, whose appointment as assistant master mechanic of the Southern Pacific, with headquarters at Sparks, Nev., was announced in last month's issue, was born on June 19, 1885, at Shoshone, Idaho. He graduated from the grammar school at Pocatello, Idaho, in April, 1901, and entered the service of the Oregon Short Line on August 27, 1902, as a machinist apprentice at Pocatello. After completing his apprenticeship, on August 27, 1906, he was promoted to shop draftsman. On January 1, 1909, he was transferred to the office of the superintendent of motive power in Salt Lake City, Utah, as a mechanical draftsman. In

April, 1911, he left the employ of the Oregon Short Line and for about a year was employed as a mechanical draftsman by the Ray Consolidated Copper Company at Ray, Ariz., returning to the Oregon Short Line on May 16, 1912, as assistant machine shop foreman at Ogden, Utah. On November 15, 1913, he was promoted to general foreman. On July 1, 1914, the shops at Ogden were turned back to the Southern Pacific, and he continued as general foreman there until August 1, 1920, when his recent appointment became effective.

CAR DEPARTMENT

J. MATTHES has been appointed chief car inspector of the Wabash with headquarters at Decatur, Ill., succeeding J. C. Keene.

ANDREW McCOWAN, master car builder of the Canadian National, with headquarters at Winnipeg, Man., has had his jurisdiction extended to the lines of the Grand Trunk Pacific. The change was effective September 1.

E. HACKING, master car builder of the Grand Trunk Pacific, with headquarters at Transcona, Man., has been promoted to assistant master car builder of the Canadian National, with headquarters at Winnipeg, Man.

SHOP AND ENGINEHOUSE

C. G. HENDERSON has been appointed general foreman of the Southern Railway at Chattanooga, Tenn., succeeding H. E. Dyke.

V. B. STORY has been made general foreman of the Rock Island shops at Amarillo, Tex., succeeding S. C. Thomas, resigned.

PURCHASING AND STOREKEEPING

GEORGE W. GROSSNER has been appointed purchasing agent of the New Orleans Great Northern, with headquarters at New Orleans, La., succeeding William Grentzenberg, resigned.

HENRY HANSEN, chief clerk to the purchasing agent of the Northern Pacific, has been appointed assistant purchasing agent, with headquarters at St. Paul, Minn.

W. C. LIVINGSTONE has been appointed division storekeeper of the Pittsburgh division of the Pennsylvania, with headquarters at Derry, Pa.

OBITUARY

ISAAC B. THOMAS, purchasing agent of the northwestern region of the Pennsylvania with headquarters at Chicago, died on September 1 in that city. Mr. Thomas was born on June 26, 1872,

I. B. Thomas

at West Chester, Pa. He was graduated from Sheffield Scientific School, Yale University, in 1892. In that year he began railroad work as an apprentice at the Altoona shops of the Pennsylvania. On August 1, 1897, he was promoted to the position of inspector at the Altoona shops, and in April, 1899, was transferred as inspector to the office of the assistant engineer of motive power. On February 1, 1900, he was appointed assistant master mechanic at Renovo, Pa., returning to Altoona in 1901 as assistant engineer of motive power.

On August 1, 1903, he was appointed master mechanic of the Pittsburgh shop and was transferred to the Altoona machine shop in 1906. He was promoted to superintendent of motive power of the Erie division of the Pennsylvania and also of the Northern Central, with headquarters at Williamsport, Pa., in 1911, and was appointed assistant purchasing agent of the Pennsylvania lines east of Pittsburgh in 1916. Upon the return of the road to private control he was appointed to the position he held at the time of his death.

SUPPLY TRADE NOTES

George J. Lynch has resigned as sales manager of the Youngstown Steel Car Company, Niles, Ohio.

Joseph S. Ralston, president of the Ralston Steel Car Company, Columbus, Ohio, died in that city on September 11, at the age of 55.

J. C. Keene, chief car inspector of the Wabash at Decatur, Ill., has accepted a position with the Bradford Draft Gear Company, Chicago, Ill.

H. D. Elvidge, assistant to the advertising manager of the Reading Iron Company, Reading, Pa., has been appointed assistant advertising manager.

Agnew T. Dice, Jr., railroad sales manager of the Reading Iron Company, Reading, Pa., has been placed in charge of the cut nail business of the company.

D. M. Brown has been appointed manager for Ontario, with headquarters at 342 Adelaide street West, Toronto, of the Holden Company, Ltd., Montreal, Que., dealers in railway supplies.

The American Automatic Connector Company, Cleveland, Ohio, on October 1 opened offices and an exhibit room at 235 Railway Exchange building, Chicago, in charge of F. R. Bolles, vice-president and general manager.

The American Steam Conveyor Corporation of Chicago, Ill., announces that a change has been made in the corporate name to Conveyors Corporation of America. There is no change either in the personnel or policy of the company.

Benjamin M. McDade, formerly sales manager of the Detroit Red Lead Works, Detroit, Mich., has become associated with the railway sales department of the Sherwin-Williams Company, with headquarters at Detroit, Mich.

L. R. Day has succeeded W. E. Allison as representative in the railroad department of the Western Electric Company at Milwaukee, Wis. E. B. Dennison has been appointed manager of the new branch office at Nashville, Tenn.

C. E. Neubert, assistant district manager of the Chicago office of the Warner & Swasey Company, Cleveland, Ohio, has been promoted to district manager of the company's office in Buffalo, N. Y., to succeed W. E. Marshall, deceased.

S. W. Fries has been appointed district sales manager for Kansas City territory of the Economy Fuse & Manufacturing Company, Chicago, with offices at 1205 Commerce building, Kansas City, Mo. Mr. Fries succeeds R. P. Crawley, resigned.

John G. Talmage, president of the Talmage Manufacturing Company, Cleveland, Ohio, died suddenly in Washington, D. C., on August 25. Mr. Talmage founded the company bearing his name in 1896 and was the active head of the same up to the time of his death. Mr. Talmage contributed many appliances in the development of the locomotive.

A company is being organized to construct freight car repair plants at St. Paul, Minn., and Minneapolis which will have capacities to repair 6,000 cars annually and can later be enlarged to handle 15,000 cars per year. The company is now in the market for machine tools and appliances suitable for equipping a modern plant of this type. Claude H. Siems, Alan G. Siems and C. C. Semple are the promoters and the company's headquarters are in the Guardian Life building, St. Paul, Minn.

James T. Lee has been added recently to the sales engineering staff of the Southwark Foundry & Machine Company, Philadelphia, Pa. Mr. Lee for several years past was vice-president in charge of sales of the Hanna Engineering Works, Chicago. It is the purpose of the Southwark Foundry & Machine Company to greatly broaden its field of activity by adding to its present

complete line of hydraulic and power machinery a full line of pneumatic riveters and foundry molding machines.

Charles H. McCormick has been appointed western representative of the railroad department of the Standard Paint Company, New York, with headquarters in the Plymouth Building, Chicago. Mr. McCormick began railway work with the Michigan Central in the mechanical department at Bay City, Mich., and later was transferred to Jackson, Mich., and Detroit, at the latter place serving as chief clerk to the superintendent of motive power for six years. He later went to the Standard Heat and Ventilation Company, at New York and Chicago, for four years, and was with the Hegeman-Castle Corporation, at New York and Chicago, for four years previous to entering the service of the Standard Paint Company.

The East St. Louis Locomotive & Car Company, capitalized at about \$5,000,000 will establish a railroad car and locomotive building and repair plant at East St. Louis, Ill. The plant, it is stated, is ultimately to employ 3,000 men. R. W. Crawford, formerly head of a car building plant at Streator, Ill., is president of the company. Options have been obtained on three sites, according to J. N. Fining, secretary of the East St. Louis Chamber of Commerce, and it is planned to begin work at once on several buildings. The plant, with buildings and tracks, is expected to cover 150 acres and to have an output of 75 to 120 freight cars per day. The company expects to be in a position to begin repair work on cars this winter.

B. B. Milner, heretofore engineer of motive power and rolling stock of the New York Central, at New York, who has become associated with the Frazar importing and export-

ing interests, as was announced in the *Railway Mechanical Engineer* for August, was born on November 5, 1881, at Hartford, Kans. In 1899 and 1900 he worked in the Parsons shops of the Missouri, Kansas & Texas, and later entered the mechanical engineering school of Purdue University, from which he was graduated in 1904. He then entered the service of the Pennsylvania as a special apprentice at Altoona. In 1907 he was in charge of arranging a complete revision of the machine tool layout at the Altoona shops, and later visited the principal railroad terminal points in a study of operating and maintenance of equipment methods. In 1908 he served in the office of W. W. Atterbury, then general manager at Philadelphia, on various betterment studies and was engaged in the introduction of improved operating statistical information. In May, 1911, he was appointed assistant master mechanic of the Philadelphia, Baltimore & Washington (now the Southern division of the Pennsylvania), at Wilmington, Del. In October, 1913, he left the service of the Pennsylvania to go to the New York Central as special engineer on the staff of the senior vice-president, A. H. Smith, and was sent to the Cleveland, Cincinnati, Chicago & St. Louis to assist in re-establishing satisfactory operating conditions after the disorganization precipitated by the floods of that year. He continued as special engineer on the staff of Mr. Smith, who had been made president, and later was appointed engineer of motive power of the New York Central under Chief Mechanical Engineer R. B. Kendig. In addition to duties as engineer of motive power, he handled problems in connection with car department work and the organization and administration of the test department headed by the engineer of tests. On May 10, 1917, Mr. Kendig died and Mr. Milner took over his entire work through the war and United States Railroad Adminis-

B. B. Milner

toona shops, and later visited the principal railroad terminal points in a study of operating and maintenance of equipment methods. In 1908 he served in the office of W. W. Atterbury, then general manager at Philadelphia, on various betterment studies and was engaged in the introduction of improved operating statistical information. In May, 1911, he was appointed assistant master mechanic of the Philadelphia, Baltimore & Washington (now the Southern division of the Pennsylvania), at Wilmington, Del. In October, 1913, he left the service of the Pennsylvania to go to the New York Central as special engineer on the staff of the senior vice-president, A. H. Smith, and was sent to the Cleveland, Cincinnati, Chicago & St. Louis to assist in re-establishing satisfactory operating conditions after the disorganization precipitated by the floods of that year. He continued as special engineer on the staff of Mr. Smith, who had been made president, and later was appointed engineer of motive power of the New York Central under Chief Mechanical Engineer R. B. Kendig. In addition to duties as engineer of motive power, he handled problems in connection with car department work and the organization and administration of the test department headed by the engineer of tests. On May 10, 1917, Mr. Kendig died and Mr. Milner took over his entire work through the war and United States Railroad Adminis-

tration period. During the latter half of 1918, or until after the armistice was signed, he assisted H. A. Worcester, the Ohio-Indiana district director, with headquarters at Cincinnati. When the railroads were returned to their owners for operation on March 1, 1920, he became engineer of motive power and rolling stock, which position he held until he joined the staff of Sale & Frazar, Ltd.

W. H. S. Bateman, trading as W. H. S. Bateman & Co., Philadelphia, Pa., who for the past six years has been the eastern representative of the Canton Sheet Steel Company, has severed his connection with that company and has been appointed eastern sales agent of the Superior Sheet Steel Company, Canton, Ohio, with offices in the Commercial Trust building, Philadelphia, Pa., and 30 Church street, New York. Joseph R. Wetherald will continue as sales manager at the Philadelphia office and Richard J. Sheridan at the New York office. Mr. Bateman will continue as resident sales manager of the Parkesburg Iron Company and eastern and southern sales agent of the Champion Rivet Company, at Philadelphia.

Announcement is made of the consolidation of the Whiting Foundry Equipment Company of Harvey, Ill., and the American Foundry Equipment Company of New York. The new organization will be known as the Whiting Corporation and will maintain the same offices and manufacturing equipment. J. H. Whiting, former president of the Whiting Foundry Equipment Company, becomes chairman of the board and V. E. Minich, former president of the American Foundry Equipment Company, president. E. A. Rich, Jr., will be in charge of the plant at 2935 West Forty-seventh street, Chicago, and R. S. Buch in charge of the York, Pa., plant. The corporation plans to maintain and enlarge the former offices of the American Foundry Equipment Company at 366 Madison avenue, New York, as the eastern sales and export office.

William S. Noble, who has been appointed manager of the railroad department of the Standard Paint Company, with offices in New York and Chicago, as was announced in the September issue, was born at Danville, Ky. He began railway work in 1887 as secretary to the vice-president of the Lehigh Valley. He was later assistant in the president's office and from 1905 to 1909 was assistant to the president of the Seaboard Air Line, the Clinchfield Coal Corporation and the Carolina, Clinchfield & Ohio Railroad at New York. He then was appointed president's assistant with the Lehigh Coal & Navigation Company, Philadelphia, and in 1914 entered the service of the Standard Paint Company, New York, in its railroad department. He subsequently served as western representative, from which position he was recently promoted to manager of the railroad department of the same company.

The Titan Steel Corporation has been organized with headquarters at Newark, N. J. It has acquired the plant of the Hewitt Steel Corporation and will enlarge and re-equip the plant for maximum production, with an initial payroll of 1,500 men. The plant in question was conducted during the war for the manufacture of steel shells. Before the war it was owned by the Titan Steel Castings Company, but at the outbreak of hostilities was acquired by the Hewitt Steel Corporation for the making of steel shell castings. It is now being re-equipped for the economical production of railroad specialties. The new company has also acquired by purchase approximately two-thirds of the capital stock of the Crown Castings Company, a holding company for patent rights and privileges for the manufacture of a truck and body bolster for railroad cars. E. H. Benners, president of the holding company and patentee of the truck and bolster, is vice-president of the Titan Steel Corporation. The Titan thus obtains the use of these patents and also one for the Benners side frame, which Mr. Benners holds. H. H. Hewitt, president of the Hewitt Steel Corporation, is a director of the new company, which also has acquired the manufacturing rights of the Hewitt car trucks and journal boxes. The officers of the company are as follows: R. E. Jennings, Sr., chairman of the board; R. E. Jennings, 2nd, president; S. A. Benners, vice-president; E. H. Benners, vice-president in charge of sales; E. E. Ledogar, treasurer, and R. J. Gill, secretary.

TRADE PUBLICATIONS

PRICE LIST.—The Poole Engineering & Machine Company, Baltimore, Md., has issued a new price list covering their various machines and equipment.

MULTI-CUTTINGS.—The R. K. LeBlond Machine Tool Company, Cincinnati, Ohio, has issued a 34-page booklet descriptive of their new semi-automatic lathe.

MURRAY STEAM POWER PLANTS.—Various engines, boilers, compressors, etc., are described and illustrated in catalogue No. 85, issued by the Murray Iron Works Company, Burlington, Ia.

KELLER PNEUMATIC TOOLS.—A catalogue has been issued by the Keller Pneumatic Tool Company, Grand Haven, Mich., illustrating and describing their complete line of pneumatic tools.

PUNCHES AND SHEARS.—The Buffalo Forge Company, Buffalo, N. Y., has issued a 64-page catalogue illustrating and describing in detail their complete line of "Armor-Plate" punches and shears, bar, angle and tool cutters, etc.

MACHINE MOLDED GEARS.—The Poole Engineering & Machine Company, Baltimore, Md., has issued a new catalogue describing machine-molded gears which they have arranged according to pitch, the prime factor in determining the strength of all gears.

THE LOCOMOTIVE BOOSTER.—The Franklin Railway Supply Company, Inc., New York, has issued bulletin No. 975, describing the operation and control of the locomotive booster. Two charts show the relative increase in power by the application of the booster.

CANTON ALLIGATOR SHEARS.—The Canton Foundry & Machine Company, Canton, Ohio, has issued a 23-page catalogue illustrating and describing "Canton" semi-steel shears, built in various styles and sizes, for cutting from 1-in. square to 3-in. square, inclusive.

BOILERMAKERS' TOOLS.—The line of railway and boilermakers' supplies manufactured by the Lovejoy Tool Company, Chicago, is listed and briefly described in catalogue No. 10, containing 32 pages, illustrated. The line includes ratchets, drilling posts, punches and dies, expanders, flue cutters, pneumatic hammers, rivet forges and ball bearing jacks for railroad use.

CHAIN BLOCKS.—The Machine Shop issue of Hoisting Hints, published by the Yale & Towne Manufacturing Company, Stamford, Conn., contains a number of illustrations of Yale spur gear chain blocks handling heavy lifting operations in machine shops of many industries. These hoists are made in 17 sizes, with capacities ranging from $\frac{1}{4}$ to 40 tons, the booklet containing prices and specifications.

RADIAGRAPH CUTTING TORCH.—The Davis-Bournonville Company, Jersey City, N. J., has issued a bulletin describing the No. 1A Radiagraph. This is a portable, mechanically operated cutting torch for cutting and beveling plate and structural steel. It cuts to straight and circular lines and when the torch is set at an angle bevels the edges of boiler plates. The bulletin shows some characteristic cutting done with it.

FORGING PRESSES.—Bulletin No. 19, containing 24 pages, has been prepared for distribution by the Morgan Engineering Company, Alliance, Ohio, describing briefly the steam hydraulic forging presses built by this company, which consist of single frame types built in sizes from 150 to 500 tons capacity and four-column types up to 12,000 tons capacity. A general arrangement drawing of a typical modern forging shop is included in the bulletin.

LATERAL MOTION DRIVING BOX.—Means for increasing the capacity of narrow-gauge locomotives by the use of the Franklin lateral motion driving box and the Economy engine truck are described in bulletin 77, a four-page pamphlet issued by the Franklin Railway Supply Company, New York. These devices permit the use of an extra pair of driving wheels, with a corresponding increase in the tractive power of the locomotive. A line drawing shows the arrangement of the box and flexible side rods.

INSTRUCTION BOOK FOR WELDERS.—A new edition of the Eveready instruction book distributed by the Oxweld Acetylene Com-

pany, Chicago, is a comprehensive treatise on every-day oxy-acetylene welding and cutting. It is a compact reference book, containing 55 pages, 5 in. by 8 in., illustrated. Practical information on modern practices in welding and cutting is presented in a manner so that it can be easily grasped by the beginner, at the same time being valuable to the experienced welder and cutter.

HAMMERS.—A Captain of Industry is the title of a booklet published by the David Maydole Hammer Company, Norwich, N. Y. It contains a brief story of the life of David Maydole, the inventor of the adz-eye hammer, written by James Parton. In addition it includes a catalogue of the principal varieties of hammers made by the company and an amount of useful information for mechanics, which has been compiled mostly in tabular form, showing the weights and specific gravity of materials of various kinds, speeds of wheels and drills, rules for calculating measurements, etc.

CARBON DIOXIDE RECORDER.—Bulletin No. 111 describing the style "U" Uehling carbon dioxide recording equipment has been issued by the Uehling Instrument Company, New York. This new design is built in single and multiple unit forms. The bulletin shows the principle of operation involved and explains the speedy action resulting from a new form of aspirator. Absence of chemical solutions, simplicity, and an auxiliary boiler front CO₂ indicator to guide the firemen, are explained as additional advantages. The recorder itself installed in the chief engineer's office makes a continuous record of CO₂ in the flue gases.

BOLT, NUT AND RIVET MACHINERY.—A complete line of equipment for the manufacture of bolts and nuts is described in catalogue No. 20, issued by the Acme Machinery Company, Cleveland, Ohio. The machines include single and multiple bolt cutters with or without power feed and lead screws, special staybolt cutters, bolt pointers, nut tappers, nut burring machines, nut machines, bolt machines and upsetting and forging machines. The Acme die head manufactured by this company is also described and instructions are given for making or recutting dies. A set of tables of data pertaining to screw threads, bolts, nuts and rivets is included.

BEARINGS AND THEIR LUBRICATION.—The Vacuum Oil Company, New York, has published a 32-page pamphlet which contains an extended discussion of the lubrication of various forms of bearings. The subject is introduced by illustrating and describing the more common forms of bearings used on various types of machinery. This is followed by a brief description of the usual method of applying the lubrication either directly or through distributing systems. Space is also given to the general discussion of lubrication in relation to the quality of oil; and the latter part of the publication is devoted to considerations affecting the selection of oil for any given purpose.

WELDING TORCHES.—The Air Reduction Sales Company, New York, has issued a catalogue describing its new line of Airco "A" and "B" welding torches. The booklet has been made as complete as possible in order to give a clear understanding of the principles of torch operation involved in the construction of the Airco apparatus and their relation to good welding. The catalogue is well illustrated with half-tone reproductions of the full line of torches, angles of heads, tips, etc. Tables are given showing the thicknesses of metal that can be welded.

STEAM TABLES FOR CONDENSER WORK.—The Wheeler Condenser & Engineering Company, Carteret, N. J., has published the fifth edition of its handbook of steam tables. The booklet is of convenient size and is illustrated. It gives the properties of saturated steam from 29.8 in. vacuum to atmospheric pressure in increments of tenths of an inch, with pressures below atmosphere expressed in inches of mercury referred to a 30-in. barometer. A complete table is also given of the properties of saturated steam above atmospheric pressure, with constants and tables for correcting vacuum column and barometer readings, such as thermal expansion of mercury, relative expansion of mercury and brass scale, etc.

THERMIT PIPE WELDING.—The Metal & Thermit Corporation, New York, has issued the third edition of its thermit pipe welding pamphlet, No. 16. In the new edition the subject of thermit pipe welding has been revised and brought up to date. The making of thermit pipe welds is described in detail. The pamphlet also contains reports on successful tensile strength and vibration

tests of thermit welds conducted by Stevens Institute, and a chart showing the comparatively low cost of a thermit welded pipe as compared with the cost of installing compression flanges with bolts and gaskets. The new edition also contains an account of a 10-year pipe test during which 700 ft. of 4-in. thermit welded pipe was constantly subjected to a hydraulic pressure of 1,500 lb. per sq. in., without requiring any attention.

AUTOMATIC CONNECTORS.—A Performance Record of the American Automatic Connector, a booklet of 16 pages published by the American Automatic Connector Company, Cleveland, Ohio, presents the results that have been accomplished through the use of this equipment on 24 steel and 76 wooden hopper ore cars, 20 passenger cars and nine locomotives on the Copper Range Railroad. These connectors were installed more than a year ago and the trains were operated in what is possibly the worst snow region on this continent. An accurate record was kept by the railroad company of the cost of maintenance, the cause for each part renewed was determined and the results obtained through the use of the connectors were carefully analyzed. These have now been published in the booklet mentioned.

GREETINGS FROM THE TEXAS COMPANY.—A small booklet entitled "Howdy," was issued by the Texas Company, New York, to delegates attending the American Railroad Association convention, at Atlantic City. The booklet acquainted convention delegates with some interesting facts regarding the Texas Company. A discussion of railroad lubrication was given by George L. Noble, vice-president and general manager of the railroad sales department and conditions in the New York and Chicago fields were described by the respective department managers. Attention was called to the provision in some localities for spray ciling the rails in order to prevent corrosion and rust, using a specially designed car for this purpose. The last few pages of the booklet give a brief but interesting account of the activities of the Texas Company, outlining the fields covered by the different departments.

STATIONARY BOILERS.—An interesting and well-illustrated 86-page catalogue, entitled Boiler Logic, has been issued by the Heine Safety Boiler Company, St. Louis, Mo. It contains a large amount of valuable information regarding boiler design, such as proper mixture of the gases, heat transmission by radiation, by convection and by transmission through the tubes to the water. Practical methods of baffling water tube boilers are described, with emphasis laid on flexibility of design, prevention of leakage, active and inactive surfaces, and ease of cleaning. Illustrations and descriptions are given of Heine boilers arranged for hand firing with bituminous or anthracite coal. Various kinds of stokers, including chain grate, side feed and underfeed stokers, are described. The catalogue illustrates different arrangements for burning fuels, including oil, shavings, bagasse and gas. Several pages are devoted to the overloading of boilers and a chart shows the relation between boiler load and excess of flue gas temperature over steam temperature. The last part takes up the design, construction and methods of shipping of Heine boilers.

INSTRUCTION BOOK FOR GRINDING MACHINE.—The Heald Machine Company, Worcester, Mass., has issued a new instruction book explaining the operation and adjustment of the Heald No. 60 cylinder grinding machine, which contains a number of new features. It includes diagrams of floor plans, fan layouts, etc., making it unnecessary to use blueprints, and the instructions include not only those for adjusting the machine, but also for setting up. There is also a section on the selection of the proper grinding wheels. Wet and dry grinding is also taken up, as well as speeds and feeds and the various size arms which the company is in a position to furnish. At the back of the book is a section devoted to repair parts. In it, instead of the usual long list of names and numbers of the various parts and photographs of them, there are a number of line drawings, the first one being of the entire machine, which is termed the master chart. When a part is broken the operator, who has the machine in front of him and knows the location from which the part came, can turn to the chart designated on the master chart, which will show that particular section or unit of the machine and the part number he desires. This number, together with the serial number of the machine, will make it possible to furnish the exact piece required and guarantee interchangeability. The book contains 80 pages, 6 in. by 9 in., and is known as bulletin 501A.

Railway Mechanical Engineer

VOLUME 94, NUMBER 11

New York—NOVEMBER, 1920—Chicago

ESTABLISHED IN 1832

Published Monthly by Simmons-Boardman Publishing Co., Woolworth Building, New York, N. Y. Subscription price, United States, Canada and Mexico, \$4.00 a year; foreign countries, \$5.00 a year; single copies 35c. Entered as second-class matter, January 27, 1916, at the post office at New York, N. Y., under the act of March 3, 1879.

Ryerson-Conradson Railroad Lathes

U. S. and FOREIGN PATENTS

Accurate for the finest Railroad work. Convenient for production.
Strength and Power for output.

NEW LOCOMOTIVES ARE ALWAYS BIG ONES

Every lot of new engines adds to the shop maintenance duty.

Shop equipment has not kept pace with the number of new and big engines.

Roundhouse machinery, generally, is woefully inadequate and antiquated.

Shops and roundhouses need the best machinery in the world.

These lathes are especially built to meet the perpetual emergency of roundhouse work—for rugged work of large variety—for production, quantity with precision.

LATHES—RADIAL DRILLS—MILLING MACHINES—PLANERS

JOSEPH T. RYERSON & SON

Proof:

Write for the Ludlum Steel text book. Yours for the asking.

SEMINOLE

UNBREAKABLE HEAVY DUTY CHISEL STEEL

This is the steel that is baffling science. File hard yet can bend under tremendous pressure, not once but many times.

Its wide hardening range is a point of unusual merit.

Seminole will withstand any usage to which it may be subjected in actual service.

You wish to reduce your chipping cost.

Specify Seminole.

-------------------	---------

The systematic analysis of shop operations is a fairly recent development. It is an inevitable result of the increase in the size of individual plants which made it impossible for the supervisory officers to gain correct and definite information regarding the operation of the properties by personal observation.

Systematizing Management in Railroad Shops

In many manufacturing plants the operations are few in number. This has facilitated the keeping of detailed records and has led to the introduction of time studies of the individual operations. At present, time studies and detailed records are the most important features of investigations of production in industry. Due to the diversity of the work in railroad shops, the introduction of these same methods involves an enormous amount of clerical work and for that reason many railroad shop men have contended that so-called scientific management methods could not be successfully used.

The argument against systematized management in railroad shops is based on objections to the methods used and not to the object to be attained. The records are the means to an end and are only useful for the results secured. Railroad shop executives who are trying to get increased output should recognize that systematic management methods have proved a great aid to industrial plants and should likewise be beneficial in railroad shops. There is no necessity for adopting the identical system that is used in industries, but by instituting a series of records that will check the progress of the work and insure that the various departments operate as a unit, troublesome delays can be avoided. The foremen could be relieved of a mass of routine duties, thus enabling them to give more time to developing improved methods and increasing the efficiency of their departments. Where no follow-up system is used in the shop, it will generally be found that the foremen spend a large part of their time trying to expedite the individual jobs. They have no means of knowing where the parts for the next locomotive that is due

out have been delayed, why the storehouse has not delivered certain material, or any of the multitude of trivial matters that hold up production.

Most railroad shops are too large to function properly without some aids to management. Just how comprehensive a system is needed for a given shop depends on the size of the plant and the local conditions. At any rate, the time has come when railroad men should recognize that systematic management is needed and should attempt to apply the principles worked out in industry to the different conditions existing in railroad shops. Are you using a shop scheduling system?

The effect of the campaign of the Association of Railway Executives to secure improved operation of the railroads is quite evident in the records recently published by the American Railroad Association and the Interstate Commerce Commission. Statistics of the Car Service Division of the A. R. A.

show that in the week ending October 9, 1,009,787 freight cars were loaded, a record that has been exceeded but once. This is the first time this year that freight car loading has passed the million mark although for several weeks the figures have been in excess of the loadings for the corresponding weeks in 1919 and 1918.

Operating statistics for the month of July show that the railroads during that month handled 15.2 per cent more freight than in July, 1919. In the first seven months of 1920 the number of tons of freight hauled one mile was 248,999,000,000 in spite of the handicap of the outlaw strikes. This is an increase of 17.1 per cent as compared with the first seven months of 1919 and also represents a greater volume of traffic than has ever before been handled by the railroads in the first seven months of the year. In July of this year the average tons of freight per car was 29.7 as com-

pared with 28 in 1919. The average mileage per freight car per day was 26.2 as against 24.1 last year.

While operating statistics for the later months are not available, the records of car loading already mentioned indicate that the performance is steadily improving. This is further shown by the fact that the accumulation of loaded cars in terminals awaiting movement, which was almost 100,000 on March 1 when the roads were returned, was reduced to 41,135 on October 8. As nearly 18,000 of these cars were being held at ports for ships, it is no exaggeration to state that congestions have ceased to exist.

The general freight car situation is also improving as shown by the fact that the car shortage for the week ending October 1 shows a reduction of 9,000 cars as compared with the previous week. Cars are being returned to the owners and on October 1, 30 per cent of the cars were on home lines, a gain of 2 per cent over September 1 and of 8.1 per cent over March 1. To offset these circumstances, however, the percentage of bad-order cars shows a slight increase from 7.0 per cent in June, 1920 to 7.2 per cent in July. Conditions are better than in July, 1919, when the percentage of bad-order cars was 8.7, but this was almost a high record and there is urgent need for more attention to car repairs in order that the unserviceable equipment may be brought down to the normal value of four per cent.

This record is splendid, but it can be still further improved by enthusiastic and intelligent co-operation of all of the departments on the railroads and of every man in each department. Mechanical department forces in particular can be a big factor in improved operation.

The chief inspector of locomotive boilers has recently reported to the Interstate Commerce Commission a crown sheet failure on a passenger train which resulted in the death of the engineer and fireman. The circumstances are somewhat unusual in that the investigation disclosed several flagrant violations of the provisions of inspection rules. The accident occurred on a Pacific type locomotive drawing a passenger train and while running at a speed of about 45 miles an hour. The crown sheet failed, permitting steam and water to enter the cab and resulting in fatal injuries to both members of the crew. The locomotive was built in 1913 and had a straight top radial stayed boiler supported by $1\frac{1}{2}$ in. stays, spaced 4 in. by 4 in. The crown sheet pocketed to a depth of 4 in. on the right side. In the pocketed area there were 37 broken bolts, 12 which were not broken which the sheet pulled off. Numerous defective stays were found outside the pocketed area. No evidence of overheating or strain was found, but after the pocketed section of the plate was cut out, an examination of the broken bolts showed that the ends were coated with considerable scale. From the appearance of the rest of the boiler, it was believed that these stays were broken some time previous to the last monthly inspection, which was made 20 days prior to the accident.

Investigation disclosed that on the previous trip, the safety valves did not relieve the pressure and it went as high as 250 lb. Nevertheless the inspectors did not believe that this was a factor in causing the accident as the stresses on the crown stays would have been well within the allowable limit.

The inspector who certified to the condition of the boiler at the last monthly inspection admitted that he did not perform the work called for on the report and that the locomotive was not fired up although the report stated that the safety valves were set on that day. It was also brought out that in setting the safety valves on the day of the accident a second steam gage, as required by law, was not used.

In commenting on the accident, the chief inspector calls attention to the laxity of the mechanical department officers in assigning men to make inspections without knowing that

they were capable of performing such work and for not supervising the work to see that the requirements of the rules were complied with. Attention is directed to the fact that the fatalities might have been avoided had the locomotive been equipped with automatic firedoors, and the use of tell-tale holes in all crown stays and staybolts, regardless of their length, is recommended.

The railroads, spurred on by the necessity of moving an unprecedented amount of freight in order to prevent a heavy curtailment of production, have made a remarkable record during the past few months. The goals which were established by the Association of Railway Executives included an average movement of each loaded freight car of 30 miles per day, with an average loading of 30 tons. During July the roads averaged 26 miles per car per day. During that month 12 of the large roads exceeded the standard for car loading and 15 roads attained an average of over 30 miles per car day. The splendid service which has been done by the car service committees and the car service organization has made it possible to break up the congestions at different points and to secure a more normal freight car movement.

One thing is interfering greatly with getting a better movement, and that is that so many of the freight cars are in poor condition. Some of them are too light and should have been retired from service long ago, and a great many others, if they are to remain in service, must be rebuilt and be very considerably reinforced. It is poor policy to try to continue to operate cars which cannot stand up under service. It means that heavy trains are continually being delayed because of defective cars and in many cases these breakdowns have wrecked good cars and have damaged or destroyed considerable amounts of freight. The mechanical department should use every influence to get the cars into good operating condition, or to see that they are set aside if they are not fit.

So large a proportion of the injuries sustained as a result of the bomb explosion which occurred recently in Wall street were directly due to broken glass falling from the shattered windows, that there was much speculation as to the extent to which these injuries would have been lessened had the use of wire glass been more general. Every accident from a broken windshield resulting from even slight automobile mishaps invites similar consideration in favor of the use of safety glass. While broken glass does not figure prominently in railroad accidents, the menace is always present.

With the wide use of wire glass and the improvement that has more recently been effected in the construction of safety glass, there is no reason why the special properties possessed by both of these materials should not be more generally taken advantage of in car and locomotive use as well as in shops, stations and office buildings.

Safety glass consists of two layers of ordinary glass cemented together, so that when struck a sharp blow it will not shatter into many flying fragments, although it may be badly cracked. When first manufactured safety glass did not have altogether satisfactory visibility, but this has been remedied and its use for automobile windshields has become popular. The same arguments in favor of its use in an automobile windshield should apply to its use in a locomotive cab; if you are willing to pay the extra price for this form of protection in your automobile, would it not be consistent to place the same glass in the locomotive cab? The use of any material that promises additional protection to employees is something to which mechanical engineers should always give serious consideration.

Better Freight Cars Needed

Use of Wired and Safety Glass

DO YOU KNOW YOUR MEN?

WILLIAM S. WOLLNER, general safety, fire prevention and welfare agent of the Northwestern Pacific, in an address before the October meeting of the New York Railroad Club on The Human Element in Railroading, drew a sharp contrast between the critical attention which is given to the selection and use of materials on the railroads and the comparative indifference which is paid to the selection and use of a far more vital factor—the men. Is it not true that this lack of appreciation of the necessity for using special skill and scientific methods in directing the human element is at the bottom of most of the labor difficulties which beset us?

A large part of the leadership on the railroads, even outside of those departments which have to do with civil, mechanical and electrical engineering problems, is in the hands of technically educated men. Young men who enter engineering courses in our colleges look forward, most of them, to the time when they will be advanced to executive positions and will have considerable forces of men working under their direction, and yet, even today, how many of our engineering courses give any adequate amount of attention to problems affecting the utilization and direction of human energy? It is true that the technical graduate today is better favored in these respects than those of us who were graduated several years ago, but even at that, in most cases, he is little better fitted in this respect when he is graduated than he is of using good English and sound logic in making up an engineering report.

On the other hand, how much real coaching or training does a foreman receive in the supervising of men when he is promoted from the ranks? He may have the highest sort of ability in this respect lying dormant, but of what use is this unless he knows how to utilize it? A cutting tool may be made of the finest kind of steel, but if it is not properly sharpened for the work which it is to do, it is inefficient and oft-times useless.

A few industries have awakened to the vital necessity of educating their foremen and subordinate officers in the art of training men and directing their work and they are getting big returns from an almost insignificant expenditure. Ordinarily a foreman or boss in railroad service is taken from the ranks and is literally thrown at the job. In some cases he fails miserably when he could have made good under intelligent direction. In other cases he stumbles along and manages to get by, but like Topsy, he "just grows up" to the job and the limited education that he receives from bitter experience costs his company heavily. In a few cases the new foreman has a rare ability as a director of men and makes good from the start, but even these men would do better and go further if aided by a comprehensive and intensive course of study. An ordinary mechanic serves four years as an apprentice to perfect himself in handling a few tools and doing a limited number of mechanical jobs. On the other hand, a foreman who must direct men, the biggest and most complex factor in production, receives no special training. Is it not logical that when a man is selected for promotion he should at least receive a course of training in the art of handling men which will take as long a time as learning how to operate a typewriting or calculating machine, and yet, whoever heard of this being done on a railroad?

If the individual railroads cannot see their way clear to provide proper training courses for such men in the various departments, why not have the roads combine into groups? Or possibly the American Railway Association could arrange to provide the necessary courses and training schools. And why should the American Railway Association not do this? At present it is concentrating all its energies on securing the best use of the present facilities, and yet, what course

could the association take which would do so much in this direction as seeing that the supervising officers were all suitably instructed and equipped in the art of handling men?

In discussing Mr. Wollner's paper J. C. Clark, assistant to the general manager of the Oregon Short Line, directed attention to the great waste on the railroads because of the excessive labor turnover. The labor turnover is a symptom of a disease and in order to locate the cause and eliminate it a thorough and scientific analysis must be made of the reasons why men leave the service. Incidentally, if the railroads realized the great expense to which they are put in breaking in new men they would be inspired to locate the weak spots in the organization and strengthen them, even at a very considerable cost. Many industries have thoroughly analyzed the labor turnover with excellent results. Railroads are not very different from industries in general and they should take advantage of what has been done in other fields. But where are the men of vision in the railroad field who will take the initiative and not only make such studies, but follow them up and take advantage of them?

Labor Turnover

The railroads have made remarkable progress in speeding up transportation and in getting the maximum use out of the present limited facilities. They will, however, have to do even more if the prosperity of the country is to go forward. If the roads do not get more use from the present equipment some of our people will have to undergo much suffering. In the last analysis, however, all of the people will feel the effects. Inefficient workmen, or skilled workmen who deliberately restrict production, may feel that they are justified in their position and that they are taking it out of the bosses or the stockholders. Under modern industrial conditions, however, we have grown so interdependent that one part of our people cannot be hurt without the entire population being affected.

Master Workmen

The New York Tribune has just published a copyrighted series of articles by Marshall Olds on The High Cost of Strikes. The following paragraph is significant:

"American public sympathy has always been, naturally and openly, on the side of labor, because its struggles were so frequently against the same big industrial 'robber barons' which the public itself was fighting and because in general in its fight with capital, labor seemed to be the under dog. But labor's overconfident, often almost mad, insistence in flaunting its fundamental doctrine of class rights, its increasingly ruthless and open infringement of the most basic and important rights of all the people to be fed and warmed and clothed, in order that some small group of the labor class may be able to draw full pay for working three days a week or in order to put one group of men instead of another group into union power, is an open challenge as to whether America is to go back to the class and group government of the Middle Ages for the benefit of some of the people, or is to stay American for the benefit of all Americans."

Wise, intelligent supervision, patient effort and simple educational measures will do much to bring those elements that are abusing their power to their senses. Fortunately the American railway workers are above the average of industrial workers in this country. We will never get anywhere, however, if those who direct them are not big enough and sufficiently well trained to know how to deal with them properly, and wisely direct their energies. If we are to have master workmen we must have expert and master foremen and executives, and the higher executives especially must have a keen and broad appreciation of the importance of the human element in the organization.

COMMUNICATIONS

ASSIGNING LOCOMOTIVES

PHILADELPHIA, Pa.

TO THE EDITOR:

The proverbial man from Mars, if he were to observe our railroads, could not fail to wonder at the assignment of engines to trains. Often locomotives are distributed seemingly as though any engine would fit any train. When the project for standard engines was under way during the war, one of the chief arguments against them was that they would not fit any particular set of operating conditions. But could the assignment of these engines to any particular division be more out of place than the assignment of engines to some trains on which they are regularly placed? I have seen within a half hour on the same piece of track a heavy Pacific engine go by hauling a four car passenger train and a light Atlantic engine loaded down with a full tonnage freight train, about twenty box cars. The Atlantic engine could easily have handled the passenger train—it had in times gone by—and as a freight engine, the Pacific could have handled practically the same tonnage as the Consolidations and done it faster.

Not many hours before writing these lines, I saw one of the finest Pacific engines in the country hauling a little local train into the station, a train any eight-wheeler could have handled. I do not believe that this road is short of eight-wheelers, it always has plenty around the repair shop farm; but it hauls plenty of little local trains with Atlantic and Pacific engines. Frequently Mogul engines are used on the same service, and I have become hardened to the sight of a Consolidation engine on passenger trains. There is even one local passenger train that I can expect to see with a Mikado.

Why should a little engine go out hauling a big train and right behind it come a little train with a big engine? Why should freight train after freight train pass, all with about the same tonnage, but with all sizes of engines? Why should a thirty-five car train have one engine and a forty-car train be double-headed? Why should some divisions have all small engines when some large ones could be used, and others have all large engines when smaller ones could be used to advantage on some of the trains?

Why should not the responsibility for the assignment of engines be placed squarely on somebody's shoulders, he to look after the location of the present power and its general assignment to trains and to have the further duty of continually investigating operating conditions with a view to developing new sizes of power to meet the requirements? He should aim as far as possible to have the right engine on the right train, shifting the engines from roundhouse to roundhouse until the best results are obtained.

It is a difficult problem, and, in general, at present is nobody's business. The superintendent of motive power has too much to do. The master mechanics are glad to keep the engines in running order. The road foreman of engines is glad to keep them going after they are turned over to the operating department. He has his hands full to keep the engines in order and scrape up an engine now and then when they get real scarce. The roundhouse foreman often is satisfied if he has any engine at all for each train. I have seen a little eight-wheel engine weighing not over 100,000 lb. go out with a seven-car express train that would have taxed the capacity of an Atlantic of twice the size. Why? It was the only engine of that division that happened to be in the house. I have seen the roundhouse foreman wonder whether any passenger engine would come in that was fit to send out on the limited in the morning, or whether he would

in the end have to use the best freight engine in the house. As far as the operating department is concerned, any engine that is big enough to haul the train will do.

It is very bad policy not to distribute the motive power to the best advantage. It costs extra money to handle little trains with big engines; it may cost extra money to handle big trains with little engines, and it is certainly unsatisfactory to all of us who have been late because the engine could not handle the train. Here lies an opportunity for increased efficiency! Why should not the job be given to a particular officer, who would have to know the whole road, the weight of trains, profile, condition of track, the characteristics and condition of each engine on the road, the train schedule, and all the other things that affect the problem, and from these things plan the distribution of motive power, keeping an eye on the order in which the engines go into the shop so as not to get stuck at any time for a particular class of engine and, in general, see that the right engine is always available and used so that we will not be treated to the spectacle of 150,000 lb. Consolidations and 320,000 lb. Mikados hauling the same weight train over the same track.

GEO. N. CLOUSER.

SHOP LABOR CONDITIONS

NEW YORK, N. Y.

TO THE EDITOR:

Labor conditions generally are improving slowly. There is still much to be done before getting back to the conditions that existed before the war. The movement now on foot by the labor leaders to nationalize the railroads through National Agreements and National Boards of Adjustment is of vital importance to the public.

If this movement goes through the present indications of there being a betterment will be reversed. Much depends on just what is done in the next few months. The time is opportune for shaking off a big per cent of the things that hamper improving conditions.

Most shops have on their hands a lot of mechanics with little or no skill; men who were employed during the war period when good men were unobtainable. These partially skilled men who have not showed any aptitude for improvement must be weeded out and good men put in their places. This move cannot be made unless there is either a marked modification made in the National Agreement on seniority rights or an arbitrary stand taken to disregard entirely all the rules and working agreements that were put in force by the Railroad Administration during government control.

Certainly the spirit of the Transportation Act was to restore each individual road to an individual operating unit so that they might deal with their own men independently, without being hampered in any manner by political influence. National Boards of Adjustment will mean a continuation in a marked degree of the conditions that built up step by step the inefficient machine that must now be rebuilt in its entirety. The public has a right to an efficient transportation machine. The roads gave them one before the war period; they can do it again if unhampered and again placed in the position of individual units so that each one's labor problems may be worked out and solved by the local officials.

The right to re-establish either the piece work system, bonus or merit system is of paramount importance. The National Agreement method of paying all men alike regardless of their skill or production capacity is entirely wrong; it can only lead to one thing—inefficiency. This octopus must be shaken off. The good workmen in the railroad shops never favored this method of rate fixing and do not favor it now. There are now lots of men looking for employment. The time is ripe for something to be done; the start must eventually be made. Why postpone the inevitable?

F. OREMAN.

MOUNTAIN TYPE LOCOMOTIVES FOR THE NEW HAVEN

Equipment Includes Feed Water Heaters and Provision for Future Application of the Booster

THE New York, New Haven & Hartford has purchased 30 Mountain type locomotives from the American Locomotive Company following closely in design the U. S. R. A. standard light Mountain type locomotives delivered to that railroad by the same builders during federal control. The new locomotives were built at the Schenectady works of the American Locomotive Company. The selection of this type for freight service is particularly significant in view of the fact that the railroad has also had experience with Mikado and Santa Fe type locomotives of recent design.

The construction of a large, well-designed classification

tance of approximately 110 miles. As this portion of the railroad is a two track line over which moves a large portion of the fast passenger service between New York and Boston, the necessity for a locomotive that can handle these freight trains at sustained speed is apparent.

Performance Characteristics

The light Mountain type was the last of the standard designs to be prepared by the Railroad Administration but the first of these locomotives completed by the American Locomotive Company was consigned to the New Haven. The performance of these first Mountain type locomotives

Mountain Type Locomotive for Fast Freight Service

yard at Cedar Hill, near New Haven, Conn., which was described in the July 30, 1920, issue of the Railway Age has placed the New Haven in a better position to utilize heavy power in freight service. It has always been a difficult matter on the New Haven to assemble heavy tonnage trains regularly for through movement on account of the character of the territory served and it may be possible that the potential tonnage rating of the Santa Fe type locomotives would be in excess of the practical limitations on this section on the line. On the other hand, the Mountain type should be able to demonstrate sustained speed with full tonnage trains in excess of the Mikado type locomotives.

The new Mountain type locomotive will operate mainly in through service between New Haven and Providence, a dis-

has been generally satisfactory and the new locomotives do not differ from them in any marked degree except for the addition of several important specialties designed to increase the efficiency and capacity of the new locomotives.

The locomotives will exert a maximum tractive effort of 53,900 lb. The line over which these locomotives will operate is along the shore of Long Island Sound and is practically level except for a few short breaks with a maximum of 0.6 per cent for a short distance. As the tonnage handled by these locomotives will be approximately 3,000 tons, they should be able to handle a large volume of through freight in conjunction with the heavy passenger traffic.

Based on the performance of the earlier Mountain type locomotives it is anticipated that the new locomotives will be

Elevation and Sections of N. Y. N. H. and H. Mountain Type Locomotive

able to operate on an average monthly fuel consumption of not to exceed 135 lb. of coal per 1,000 ton-miles. The locomotives will, of course, make a very much better fuel performance between terminals and although these locomotives have been in service only a short time, they have already shown remarkable economy in the use of fuel. A close record is being kept of their performance and three of the locomotives recently effected an average record of 62 lb. of coal per 1,000 ton-miles between terminals with an average train load of 2,968 tons. One of these locomotives was equipped with a feedwater heater which is part of the regular equipment applied to five of these locomotives.

Changes in the Standard Design

The general dimensions of the new locomotives are practically identical with the U. S. R. A. standard light Mountain type locomotives described in the July, 1919, issue of the *Railway Mechanical Engineer*. The boiler and firebox are the same with the exception of a small increase in the number of staybolts applied and an increase in superheater heating surface from 966 sq. ft. to 1,009 sq. ft. The engine truck presents the first noticeable departure; this is of the constant resistance type with Commonwealth cast steel truck

ble effort must be made to obtain the maximum service from every pound of coal. Feedwater heaters of the exhaust steam type appear to offer possibilities for a very large fuel saving particularly on the long level pulls where the locomotives will be continuously exhausting steam.

Future Application of Booster

The application of a booster to the trailing truck of these locomotives should materially increase the maximum tractive effort available for starting trains and might eliminate the services of a pusher used in assisting the trains over Branford Hill, a short distance out of the Cedar Hill yard. The railroad has probably had this in mind in providing for the future application of the booster to the extent of equipping all of the locomotives with trailing truck axles so designed that booster gears can be applied without necessitating new axles. The trailing truck is of the Woodward-Commonwealth type and the trailing truck brake is also arranged for the possible future application of the booster.

The most interesting detail in this connection is the use of a single hopper ashpan. The base of the pan slopes forward to a single drop door in advance of the trailer truck axle. The purpose of this design was to facilitate the application

Single Dump Ash Pan Designed to Facilitate Booster Application

frame. Wheel dimensions are the same but the distribution of weight is changed as shown in the following table:

	Light Mountain type locomotive	
	New N. Y., N. H. & H.	U. S. R. A. standard
Total weight, lb.....	328,500	327,000
Weight on drivers, lb.....	229,000	224,500
Weight on engine truck, lb.....	47,000	49,500
Weight on trailing truck, lb.....	52,500	53,000

The important specialties applied to these locomotives include the following: Duplex stoker, Franklin firedoor, Franklin grate shaker, Radial buffer and Unit drawbar, Alco flexible staybolts (1773 applied), Chambers throttle valve (modified design), Lewis power reverse, and Southern valve gear.

The cylinders are cast with by-pass value chambers to permit the future application of the railroad company's standard by-pass valves.

Application of Feedwater Heater

The feedwater heater and feedwater pump is an important addition to these locomotives. The apparatus has been applied to five engines and the arrangement of the running board and air pumps on the left hand side of the remaining 25 locomotives is such as to facilitate the application of this device at a later date. The Locomotive Feedwater Heater Company's standard apparatus is used. This includes a type E-1 heater and a 6 1/2 in. pump having a capacity of approximately 7,500 gal. an hour.

The railroad has adopted an open-minded attitude toward the application of feedwater heaters. The fuel problem is acute on the New Haven and it is realized that every possi-

of the booster, although it appears that a further change would have to be effected in the design in order to provide sufficient clearance for the booster mechanism.

Principal Dimensions

The principal dimensions and data for these locomotives are as follows:

GENERAL DATA	
Construction number	62205—34
Gage	4 ft. 8 1/4 in.
Service	Freight
Fuel	Bituminous coal
Tractive effort	53,900 lb.
Weight in working order.....	328,500 lb.
Weight on drivers.....	229,000 lb.
Weight on leading truck.....	47,000 lb.
Weight on trailing truck.....	52,500 lb.
Weight of engine and tender in working order.....	511,000 lb.
Wheel base, driving	18 ft. 3 in.
Wheel base, total	40 ft. 0 in.
Wheel base, engine and tender.....	75 ft. 7 1/2 in.
RATIOS	
Weight on drivers ÷ tractive effort.....	4.25
Total weight ÷ tractive effort.....	6.1
Tractive effort × diam. drivers ÷ equivalent heating surface*.....	660
Equivalent heating surface* ÷ grate area.....	80.1
Firebox heating surface ÷ equivalent heating surface* per cent.....	6.2
Weight on drivers ÷ equivalent heating surface*.....	40.7
Total weight ÷ equivalent heating surface*.....	58.3
Volume both cylinders	19.9 cu. ft.
Equivalent heating surface* ÷ vol. cylinders.....	283.2
Grate area ÷ vol. cylinders.....	3.5
CYLINDERS	
Kind	Simple
Diameter and stroke.....	27 in. by 30 in.
VALVES	
Kind	Piston
Diameter	14 in.
Greatest travel	7 in.
Steam	1 1/4 in.
Exhaust clearance	3/16 in.
Lead	3/4 in.

WHEELS

Driving diameter over tires.....	69 in.
Driving journals, main, diameter and length.....	12 in. by 13 in.
Driving journals, others, diameter and length.....	10 in. by 13 in.
Engine truck wheels, diameter.....	33 in.
Engine truck, journals.....	6½ in. by 12 in.
Trailing truck wheels, diameter.....	43 in.
Trailing truck, journals.....	9 in. by 14 in.

BOILER

Style.....	Conical, connected
Working pressure.....	200 lb. per sq. in.
Outside diameter of first ring.....	78 in.
Tubes, number and outside diameter.....	216—2¼ in.
Firebox, length and width.....	120½ in. by 84¼ in.
Firebox plates, thickness.....	Tube and throat, ½ in.; others, ¾ in.
Firebox water space.....	Front, 6 in.; others, 5 in.
Flues, number and outside diameter.....	40—5½ in.
Tubes and flues, length.....	20 ft. 6 in.
Heating surface, tubes.....	2,597 sq. ft.
Heating surface, flues.....	1,176 sq. ft.
Heating surface, firebox, including arch tubes.....	348 sq. ft.
Heating surface, total.....	4,121 sq. ft.
Superheater heating surface.....	1,009 sq. ft.
Equivalent heating surface*.....	5,635 sq. ft.
Grate area.....	70.3

TENDER

Tank.....	Water leg
Frame.....	Cast steel
Weight.....	182,500 lb.
Wheels, diameter.....	33 in.
Journals, diameter and length.....	6 in. by 11 in.
Water capacity.....	10,000 gal.
Coal capacity.....	16 tons

*Equivalent heating surface = total evaporative heating surface + 1.5 times the superheating surface.

COMMITTEE APPOINTMENTS OF MECHANICAL DIVISION, A. R. A.

The American Railway Association has recently issued a list of the standing and special committees appointed by the General Committee to serve until June, 1921. The committees have been given alphabetical designations as well as names. Those committees having a number after the designating letter are considered a part of the committee whose letter they bear and the chairmen of such committees are expected to attend meetings of the main committee. A list of the committees and the chairmen is given below.

Standing Committees

- A—Arbitration. T. H. Goodnow (Chairman), superintendent car department, Chicago & North Western, Chicago.
- A-1—Prices for Labor and Material. A. E. Calkins (Chairman), superintendent rolling stock, New York Central, New York.
- B—Arrangements. W. J. Tollerton (Chairman), general mechanical superintendent, Chicago, Rock Island & Pacific, Chicago.
- C—Autogenous and Electric Welding. J. T. Wallis (Chairman), chief of motive power, Pennsylvania System, Philadelphia.
- D—Car Construction. W. F. Kiesel, Jr. (Chairman), mechanical engineer, Pennsylvania System, Altoona, Pa.
- D-1—Brake Shoe and Brake Beam Equipment. W. J. Bohan (Chairman), assistant general mechanical superintendent, Northern Pacific, St. Paul, Minn.
- D-2—Couplers and Draft Gears. R. L. Kleine (Chairman), assistant chief of motive power, Pennsylvania System, Philadelphia.
- D-3—Train Brake and Signal Equipment. T. L. Burton (Chairman), consulting air brake engineer, New York Central, New York.
- E—Car Wheels. W. C. A. Henry (Chairman), general superintendent motive power, Pennsylvania System, St. Louis, Mo.
- F—Committees. T. H. Goodnow (Chairman), superintendent car department, Chicago & North Western, Chicago.
- G—Locomotive Construction. H. T. Bentley (Chairman), superintendent motive power and machinery, Chicago & North Western, Chicago.

- G-1—Design and Maintenance of Locomotive Boilers. G. H. Emerson (Chairman), chief of motive power and equipment, Baltimore & Ohio, Baltimore, Md.
- G-2—Feed Water Heaters for Locomotives. F. M. Waring (Chairman), engineer tests, Pennsylvania System, Altoona, Pa.
- G-3—Fuel Economy and Smoke Prevention. William Schlafge (Chairman), mechanical manager, Erie, New York, N. Y.
- G-4—Mechanical Stokers. M. A. Kinney (Chairman), superintendent motive power, Hocking Valley, Columbus, Ohio.
- H—Loading Rules. R. L. Kleine (Chairman), assistant chief of motive power, Pennsylvania System, Philadelphia, Pa.
- I—Manual. W. E. Dunham (Chairman), assistant superintendent motive power and machinery, Chicago & North Western, Chicago.
- J—Nominating. F. W. Brazier (Chairman), assistant to general superintendent rolling stock, New York Central, New York.
- K—Safety Appliances. C. E. Chambers (Chairman), superintendent motive power and equipment, Central Railroad of New Jersey, Jersey City, N. J.
- L—Specifications and Tests for Materials. F. M. Waring (Chairman), engineer tests, Pennsylvania System, Altoona, Pa.
- M—Subjects. Willard Kells (Chairman), general superintendent motive power, Atlantic Coast Line, Wilmington, N. C.
- N—Tank Cars. A. W. Gibbs (Chairman), chief mechanical engineer, Pennsylvania System, Philadelphia, Pa.

Special Committees

- O—Amalgamation of Other Mechanical Organizations with Section III-Mechanical, of the American Railroad Association. W. O. Thompson (Chairman), general superintendent rolling stock, New York Central, Buffalo, N. Y.
- P—Car Repair Shop Layouts. I. S. Downing (Chairman), general master car builder, Cleveland, Cincinnati, Chicago & St. Louis, Indianapolis, Ind.
- Q—Design, Maintenance and Operation of Electric Rolling Stock. G. C. Bishop (Chairman), superintendent motive power, Long Island railroad, Richmond Hill, N. Y.
- R—Engine Terminals, Design and Operation. C. E. Fuller (Chairman), superintendent motive power and machinery, Union Pacific, Omaha, Neb.
- S—Lateral Motion on Locomotives. Willard Kells (Chairman), general superintendent motive power, Atlantic Coast Line, Wilmington, N. C.
- T—Locomotive Headlights and Classification Lamps. W. H. Flynn (Chairman), superintendent motive power, Michigan Central, Detroit, Mich.
- U—Modernization of Stationary Boiler Plants. L. A. Richardson (Chairman), mechanical superintendent, Chicago, Rock Island & Pacific, Des Moines, Iowa.
- V—Scheduling of Equipment Through Repair Shops. Henry Gardner (Chairman), corporate mechanical engineer, Baltimore & Ohio, Baltimore, Md.
- W—Standard Blocking for Cradles of Car Dumping Machines. J. McMullen (Chairman), superintendent car department, Erie, New York, N. Y.
- X—Standard Method of Packing Journal Boxes. C. J. Bodemer (Chairman), assistant superintendent machinery, Louisville & Nashville, Louisville, Ky.
- Y—Train Lighting and Equipment. J. R. Sloan (Chairman), chief electrician, Pennsylvania System, Pittsburgh, Pa.
- Z—Train Resistance and Tonnage Rating. O. P. Reese (Chairman), superintendent motive power, Pennsylvania System, Toledo, Ohio.

THE PROBLEMS OF THE SUPERVISING OFFICERS*

Their Duties and Responsibilities Under Private Railroad Management; Organization of Foremen

BY SAMUEL O. DUNN

Editor, *Railway Age* and Vice-President Simmons-Boardman Publishing Co.

THE invitation of your president to talk to you made me anxious to avail myself of the opportunity to come here and meet you. I was much gratified when, in our conversation your president, Mr. O'Neill indicated he was familiar with the editorial policy which always has been followed by the *Railway Age*, the *Railway Mechanical Engineer*, and the other railway papers of which I am editor-in-chief, in the discussion of the problems of the railway supervising officer. It has been our uniform policy to urge upon the managements of the railways the wisdom of employing an adequate number of supervising officers in all departments, and of paying them salaries commensurate with their duties and responsibilities. As you know, the struggles between the railroad labor organizations and the railway companies have in the past frequently resulted in some conductors, locomotive engineers and other employees being paid wages exceeding the salaries of shop foremen, trainmasters, yardmasters and other officers having supervision over their work. In the editorial columns of our papers, we have contended that only in very exceptional cases could there be any justification for any employee in the ranks being paid higher wages than the supervising officers—that the efficiency of operation and justice to the supervising officers demanded that in almost every case the supervising officer's compensation should exceed, and substantially exceed, the wage of any of his subordinates. We took this position when the railways were under private operation. We took it when they were under government control. We have taken it since they have been returned to private operation.

In view of these facts, it has been a source of some gratification to me that immediately after the recent large advance in wages to employees was granted by the Railroad Labor Board the Association of Railway Executives voluntarily took up the general question of the salaries of supervising officers and urged the managements of the individual lines promptly to revise them on a basis which would make them reasonable and fair as compared with the new wages to be paid to the employees. I do not know how many railway managements have followed this advice, but I have no hesitation in saying that it is advice which every railway management ought to follow.

The Position of Supervising Officers

The supervising officers of all classes, and in the mechanical, maintenance of way and transportation departments especially, are the points of contact between the railway managements, on the one hand, and the employees, on the other. It is, under private ownership, the function of the management to determine the policies adopted in the development, maintenance and operation of the railways. It is the function of the supervising officers to see that the employees work in such a manner as efficiently to carry out these policies.

The position of supervising officers, under present conditions, is one of difficulty and delicacy. There is more or less uncertainty in the minds of many supervising officers in regard to their proper relations to the owners and man-

agers, on the one side, and the employees, on the other. Naturally it is the desire of all supervising officers to make their own situation as favorable as practicable with respect both to conditions of employment and compensation. There is, unfortunately, a large amount of antagonism between the managements, on the one side, and the labor unions, on the other. Placed as they are between these two elements, many supervising officers question whether it is their duty and to their interest to identify themselves principally with the managements, on the one side, or the organized employees, on the other.

Should Supervisors Be Identified with the Unions?

I think we can agree that the fundamental need of all of us—the railway managements, supervising officers, employees and the public—is that the railways shall be adequately developed and shall be operated as efficiently as possible. I mean by adequately developed, that their facilities shall be sufficiently increased to enable them satisfactorily to handle all the traffic that the American people and American industries can produce and offer to them. By efficiently operated I mean, so operated that the very greatest practicable service will be obtained from every ton of material and fuel used, from every mile of track, every locomotive and every car, and that every officer and employee shall do the most and the best work he can consistent with having reasonable hours of work and maintaining himself in good health. The railways are one of the most important parts of our national machinery of production. The efficient operation of all our machinery of production is essential to increasing our production of the necessities, comforts and luxuries of life. An increased production of the necessities, comforts and luxuries of life is essential for the promotion of the welfare of all of us, and especially of the working classes themselves. The second point upon which I think we can agree is that we should adopt on our railways, and in our other industries, not only that system which will secure the greatest practicable production, but also that system which will secure the most equitable division of what is produced among all who participate in producing it.

But under what system of ownership and management of the railways and other industries will we secure the greatest efficiency in production, and the greatest equity in the division of what is produced? Upon this question there are the widest differences of opinion. With respect to the railways there are, on the one side, those who advocate private ownership and management, while, on the other side, there are those who advocate the Plumb plan. Whether supervising officers will decide that they ought to identify themselves with the managements of the railways as they have in the past, or associate themselves more or less with the employees in the disputes arising between the managements and the employees, doubtless will be determined largely by which system of railroad ownership and management they favor. It is not necessary for me to tell you that the railroad brotherhoods have made, and still are making, efforts to get supervising officers of all classes to align themselves with the brotherhoods and adopt the ordinary union methods of dealing with the managements regarding their conditions

* From an address delivered at a meeting of the International Association of Railroad Supervisors of Mechanics, Milwaukee, Wis., September 22, 1920.

of employment and wages, and to support the Plumb plan of railroad ownership and management.

Importance of the Attitude of the Foremen

It is of great importance to the railway companies, and also to the supervising officers, that the supervising officers should decide wisely regarding the stand that they are going to take concerning the differences which arise between the railway managements and the employees. The managements of the railways cannot operate them efficiently under private ownership unless they can rely upon the supervising officers to carry out the policies of the managements thoroughly and to so direct the employees as to get the best practicable service from them. Let me ask you, therefore, to consider for a moment some of the arguments for the Plumb plan, and some of the arguments for a continuance of private ownership and management.

Under the Plumb plan, the public would buy the railways and guarantee their operating expenses and the interest on the money invested in them. Thus the public would assume all the risks of losses being incurred. The managing board of the railways would be composed one-third of representatives of the public, one-third of representatives of the officers, and one-third of representatives of the employees. This means that it would be composed two-thirds of employees, since under this system there would be practically no difference between officers and employees. A board composed entirely of officers and employees would fix all salaries and wages. If any surplus over interest on the investment in the railways were earned, the employees would get one-half of it. It is claimed that the adoption of this plan would establish industrial democracy on the railways, and would be beneficial to those employed by them and to the public.

Defects of the Plumb Plan

To my mind, the plan has one fatal defect. No business is ever well managed unless it is managed either by its owners or by persons selected and removable by them. The reason is, that in order that a business may be well managed it must be managed by or on behalf of persons who will not only gain if it is well managed, but lose if it is badly managed. Under this plan, all the risks of loss would be taken by the public and not by the employees, who would be in control of the management, while if any profits were made the public would get only one-half of them and the employees the other half.

But, the advocates of the Plumb plan answer, the employees are now opposed to private ownership and management because if any profits are made they go to the rich capitalists, who are alleged to own the railways, and the employees cannot any longer be expected to work efficiently to produce profits for the capitalists. As a matter of fact, this allegation that the owners of the railways get the bulk of the benefits of their operation under private ownership is not true. In 1917, the last full year of private operation, the employees received in wages about \$1,750,000,000, while the net operating income of the railways, out of which all interest and dividends had to be paid, was about \$1,000,000,000. Since then the wages of the employees have been advanced to \$3,600,000,000, or over 100 per cent. Of this advance in their wages \$625,000,000 has been given by the Railroad Wage Board since the railways were returned to private operation, thus showing that under private ownership and management the employees can get large advances in wages if they are entitled to them. If the advances in freight and passenger rates recently granted yield as large earnings as they are expected to, the net operating income of the railway companies will be made only a very little more than it was in 1917. In other words, although the employees have been granted increases in wages exceeding 100 per cent, the owners of the railways have been granted

practically no increases at all in the net operating income from which their interest and dividends must be paid.

How Employees Could Control the Railroads

Furthermore, it is not necessary to adopt the Plumb plan, nor any other plan of government ownership, to enable the railway employees to come into control of the management of the railways. They could acquire control of the management by acquiring the ownership of a majority of the stock of the railroads. Now, it may occur to you that this would be a difficult thing for them to do, but, let us see. The total outstanding stock of the railways amounts to \$6,580,000,000. The recent advances in the wages of the employees was \$625,000,000 a year. By a very simple calculation you will find that by merely saving their recent advance in their wages and investing it in railway stocks, and also investing in stocks the dividends they would receive from them, the railway employees could buy a majority of the stock of every railroad in the United States at par in five years. But at the present time the stocks of the railways are not selling at par, or for \$100 a share, but for an average of less than \$60 a share. On the basis of the prices at which railway stocks are selling now, if the railway employees would save merely their recent advance in wages and invest it in railway stocks they would, in three years, own a majority of the stock of all the railways in the United States, which would give them absolute control of the management.

But it may be said that the employees will never do this, that they will not make the sacrifices necessary to save the money, and that while they are capable of forming powerful labor unions they are not capable of so organizing themselves as to use their financial power. But to make such arguments is equivalent to contending that the employees are not capable of managing the railways, because men who have not enough self-control to save a comparatively small part of their incomes, or enough brains to invest it wisely, have not the ability to manage the railways of the United States. If they have not the ability to manage the railways of the United States, then of course the adoption of the Plumb plan would be disastrous to the public and, in the long run, to the employees themselves.

Duties of the Railroad Officers

On the whole, it seems to me that the arguments against adopting the Plumb plan and continuing the present system of private ownership and management are overwhelmingly conclusive, since under the present system of private ownership and management the employees already have the power to acquire control of the ownership, and through it the management of the railways, if they have the character and brains to do it. But if the system of private ownership should be continued, then it seems to me the duty of every railway officer, high and low, and the duty of every employee is obvious. Their duty is, first, to put forth their best efforts to promote the most efficient possible operation of the railways, and, secondly, having done this also to exert themselves to get for themselves the working conditions and the compensation to which they are justly entitled. As to the supervising officers specifically, it seems to me their plain duty is, acting for the management, to treat the employees fairly but at the same time to spare no effort to cause every employee to give a fair day's work for a fair day's wage. What is a fair day's work? I have never opposed or criticised the establishment of the eight-hour day in industry, although I believe there are conditions under which it is desirable that a man should work more than eight hours. I began my working life as a printer and spent ten hours each day in work and my evenings in study, and I have had to work and study considerably more than an average of ten hours a day all my life because I had to educate myself. As for eight hours' work, it is as little as any man ought to do in a day, and if a man works only

eight hours he ought throughout the day to do the best and the most work of which he is capable. If all of us are to be supplied with the necessities, the comforts and the luxuries which are essential for human existence and happiness, the world's production must be increased and it cannot be increased sufficiently, at least under present conditions, to provide the necessities, comforts and luxuries for all of us unless we all work hard and well.

The Present Problems of the Railroads

At the present time, as you know, the railways are unable to transport all the commodities that this country can produce, and their inability to do so is limiting the amount of commodities that are being produced. Failure to increase the facilities and capacity of the railways would mean that there could not be any further increase of the production of coal for our industries or homes, grain from which to make our bread, and of lumber and other materials from which to construct additional business buildings and houses in which to live. Therefore, no matter how you view it, failure to maintain and increase the efficiency with which the railways are operated is bound to result in a national calamity from which we shall all be sufferers.

The immediate problem confronting the railways is that of handling all the traffic that is physically possible with the facilities they have at the least practicable expense, consistent with the present wages of labor and the present prices of material. Another problem none the less pressing which is confronting them is that of increasing the facilities so they may be able to handle more business than possibly can be handled with existing facilities.

I have no criticism whatever to make upon men having common interests who organize as you have to promote those interests, but such organizations should be made not obstacles but aids to furthering not only the interests of their members, but also the interests of the industries in which those composing them are employed, and also the interests of the public. It seems to me very plain, and I am sure it is plain to you, that it is to the interest of the railways, to the interest of the public and your own interest that you shall use all your influence and all your ability to increase in every way you can the efficiency of the operation of the railroads of the United States.

SEVENTY-THREE-YEAR-OLD LOCOMOTIVE IN SERVICE IN ENGLAND

BY E. C. POULTNEY,
M. Am. Soc. M. E., A. M. Inst. M. E.

Much interest has been caused recently by the reappearance of the famous London & North Western locomotive "Cornwall" in main line service. The photograph accompanying this article shows the engine "Cornwall," now 73 years old, assisting the "Patriot,"* one of the latest London & North Western 4-cylinder superheaters express locomotives of the "Claughton" class on the 1:15 P. M. Scotch Express from London. A description of the "Claughton" class express locomotives will be found in the *Railway Mechanical Engineer* for November, 1915. The following particulars and brief historical sketch of the locomotive "Cornwall" may be of interest:

The "Cornwall" was built during that period of English railway history known as "the Battle of the Gages," occasioned by the policy of the then Great Western directors, acting on the advice of their engineer Brunel, in adopting the 7-ft. gage as against the 4 ft. 8½-in. gage inaugurated by Stephenson and used on all other lines. Excellent records for speed having been claimed for the Great Western 8-ft. single driver express engines, Francis H. Trevithick, then the locomotive engineer of the London & North Western at Crewe, and a strong advocate of the narrow or 4 ft. 8½ in.

gage, built, in 1847, the engine "Cornwall" having single driving wheels 8 ft. 6 in. in diameter, with the idea of showing that whatever could be done in the way of speed on the broad gage could be equally well done on the narrow. The engine was completed in November, 1847, and when first built the boiler was placed below the driving axle in order to obtain a low centre of gravity. Two steam domes were fitted to the original boiler, each joined together by an internal steam pipe taking steam to the "outside" cylinders, which were 17½ in. by 24 in. A safety valve was fitted to each dome.

It does not seem to be quite clear as to how many wheels the engine had when first built; some say eight were used—four in a group at the leading end, but not in the form of a "Truck" or "bogie," then the drivers and a single pair at the trailing end. Drawings of the engine thus equipped have several times appeared, but it is thought that such an arrange-

English Locomotive "Cornwall"

ment was only proposed prompted by the fact that several Great Western engines of the period were so designed, and that in reality the engine always ran on six wheels as shown in the photograph. In 1858 the engine was rebuilt with a new boiler placed above the axle. Before being rebuilt the engine was shown at the London Exhibition of 1851. It is also reported to have attained a speed of 117 m.p.h. down a grade between Madeley and Stafford on the North Western main line. After being rebuilt a second time by the late F. W. Webb, the engine was stationed at Edgehill, near Liverpool, in 1890, and was principally used in running the 45-minute express trains between Liverpool and Manchester. The "Cornwall" was taken off the Liverpool and Manchester trains in 1902, and finally was taken out of service in August, 1905, being considered amongst those whose work is done. The engine was actually in work 58 years, and from the time it was rebuilt in November, 1858, to August, 1905, it ran 928,838 miles. No record of her mileage prior to 1858 is available.

After being taken out of service the engine was used for the Chief Mechanical Engineer's private coach; the coach, which runs on six wheels, being arranged with a coal bunker at one end, was coupled direct to the engine, a tender being dispensed with.

The following are the leading dimensions of this interesting locomotive:

Heating surfaces:	
Tubes	981.0 sq. ft.
Firebox	87.3 sq. ft.
Total	1,068.3 sq. ft.
Grate area	15.0 sq. ft.
Weights in working order:	
Leading wheels	21,952 lb.
Driving wheels	28,000 lb.
Trailing wheels	13,440 lb.
Total	63,392 lb.

Diameter of driving wheels	8 ft. 6 in.
Size of cylinders	17½ in. by 24 in.
Steam pressure	140 lb.

*This locomotive was named "Patriot" in memory of the L. & N. W. employees who were killed in the war.

London and Northwestern Locomotive Equipped for Burning Oil

ENGLISH RAILWAYS EXPERIMENT WITH FUEL OIL

Description of the Scarab Fuel Oil Burning Apparatus Tested on the London and Northwestern

SEVERAL months ago the London and Northwestern equipped one of its locomotives for burning fuel oil in place of coal. The locomotive has since been operating successfully in various classes of service and if the object of this test is to determine whether the use of fuel oil would be successful from a service standpoint, the re-

sults have so far been eminently successful. The extension of fuel oil use to additional locomotives will, it is presumed, depend very largely upon the availability of this fuel in comparison with coal. The experiments were undertaken on the initiative of the London and Northwestern but the results, particularly from an economic standpoint, will be of importance to all English railways.

under oil, and, after carrying out a series of preliminary runs and assisting main line trains, it was put into passenger service, first on a slow train to Bletchley, then on a medium fast train to Rugby, and finally on the London and Birmingham service.

The firebox of the locomotive is of the narrow deep type and presented considerable difficulties in the way of fitting a satisfactory oil burning system. The minimum permissible clearance between the bottom of the ashpan and the rails is such that no little ingenuity was necessary in order to fit a suitable oil burning ashpan with its necessary air ducts. To secure the maximum efficiency with liquid fuel, in a furnace, and obtain complete combustion without excess of air or the production of smoke it is necessary to provide a burner capable of thoroughly atomizing the oil

Details of Scarab Burner

sults have so far been eminently successful. The extension of fuel oil use to additional locomotives will, it is presumed, depend very largely upon the availability of this fuel in comparison with coal. The experiments were undertaken on the initiative of the London and Northwestern but the results, particularly from an economic standpoint, will be of importance to all English railways.

Application of Oil Burning Equipment

The work of conversion to oil burning was carried out at the Bow Works of the London and North Western Railway Co. Certain of the parts were manufactured at the Crewe Works, while others were supplied by the Scarab Oil Burning Company of London. Immediately upon the completion of the work at Bow, the locomotive was steamed out

Top View of Scarab Burner

without liability to stoppage on any account, and of performing this atomization with equal efficiency over a wide range of consumption. The interior of the furnace should be so fitted with firebrick that the atomized oil is completely consumed, and the flame so directed that the heat generated is applied most efficiently to the heating surface of the boiler. It is necessary, further, that the air supply and its

control be so arranged that only the requisite amount of air necessary to complete the combustion is admitted at such points that complete combustion is at once formed.

Description of Apparatus

The Scarab burner does not differ in principle or mode of operation from the type of oil burner ordinarily used in locomotive service in this country. The fuel oil is led by means of a pipe under control of a needle valve to the upper side of what may be termed an open-ended tray. The oil falls on to this tray and immediately spreads over the whole surface, eventually finding its way over the open end in the form a fine stream or ribbon. A number of small fins are arranged along the open edge, in order to ensure that the ribbon of oil passing over the edge is of even thickness from side to side. Immediately under the tray previously referred to, is a space to which the steam or air forming the atomizing agent is led by pipes under the control of a valve. The atomizing agent is supplied at a pressure up to 15 lb.

gallons per hour capacity, and are used as "pilot" burners for maintaining steam while the engine is standing.

Elaborate Brick Arch Arrangement

A low arch is provided immediately over the burners, in order that the heat of the first ignition of the oil spray may be concentrated, and complete combustion effected as soon as possible. A small arch before the coal fire door serves to deflect the rush of flame from this door and the arch across the center of the firebox directs the flame all over the fire box surfaces and obviates a short circuit to the boiler tubes. A certain quantity of air is admitted through the burner casings themselves. This air is not under control, and simply provides the oxygen necessary for the initial combustion of the oil spray. Additional air enters through a damper placed below the firebox, and it is heated by its contact with the hot surfaces of the ashpan exposed to the flame. A considerable proportion of air travels to the burner by a passage provided immediately underneath the nozzle:

Arrangement of Oil Burning Apparatus Applied to English Locomotive

per sq. inch for the maximum rate of burning, and is controlled down to about 5 lb. per sq. inch for the lowest rate of burning.

By reference to the general arrangement drawing herewith, it will be seen that the burners are placed in the smoke-box end of a special ashpan below the foundation ring of the firebox. The flame is projected towards the rear end of the firebox, and thence deflected towards the tubeplate; in conformity with the almost universal practice in this country, three burners are installed, and they are so connected to the oil and steam supply that the center burner, the two outside burners, or all three burners can be used. However, after some preliminary runs were made, it was found that the best results were obtained with the center burner operating only, and this burner was accordingly provided with a nozzle capable of dealing with 160 gallons of oil per hour. The outside burners are now provided with nozzles of about 20

a further portion enters the furnace through a number of small holes in the firebrick false bottom of the ashpan, a few feet in front of the burner nozzle. The remainder of this air supply is allowed to pass into the furnace close to the back plate of the firebox, and, having been highly heated on its way, it is admitted to the furnace so as to provide the necessary oxygen to complete the combustion of the already ignited oil spray.

The steam for atomization is taken from the top of the boiler to a reducing valve set to deliver steam at 15 lb. pressure, which is conveyed to a receiver placed longitudinally in a space provided at the back of the ashpan. A safety valve is provided on the low pressure side of the pipe line. From the receiver, steam is conveyed by pipe lines to the burners through regulating valves operated from the cab. A connection for starting up the engine from cold by means of an auxiliary supply of air or steam is fitted in the

cab. This connection is also fitted with a pipe leading from the blower ring in the smoke-box for creating a draught when starting up. Low pressure steam is taken from the receiver back to the oil heater on the tender, also to the oil pipe line leading to the engine, suitable valves being fitted so that all oil in the pipe line may be blown out into the ashpan at the end of the day's run. This ensures that the oil pipes will be clear for starting up when required. From the main oil tank the oil flows by gravity through a specially designed heater. A thermometer is provided on the oil pipe line immediately after the heater to register the temperature of the oil. To prevent waste of steam through the heater, a steam trap is provided.

Results of Tests

Test runs which have been made with this locomotive indicate an average oil consumption of under 30 lb. per mile as compared with the coal consumption of 70 lb. per mile of this locomotive when it formerly used coal as fuel. The oil which has generally been used was of a very dark brown color and asphaltic in odor. The specific gravity at 60 deg. F. is 0.907, the flashing point is 180 deg. F., the viscosity at 70 deg. F. is 290 secs. The distillate is free from tar acids, and the calorific power is equivalent to 19,366 B.t.u.

The following table shows in detail the results that have been secured on this locomotive with oil fuel.

RESULTS WITH OIL FIRED LOCOMOTIVES ON LONDON AND NORTHWESTERN

CAST IRON FOR LOCOMOTIVE CYLINDER PARTS

Frequent renewal of cylinder parts of locomotives results in greatly increased cost of maintenance to the railroads, and consequently the quality of the cast iron entering into their construction is a matter of paramount importance, particularly from the standpoint of wear. These parts include piston-valve bushings, piston-valve packing rings, piston-valve bull rings, cylinder bushings, piston packing rings, and piston-head or bull rings. It was found that ordinary high-silicon cast iron gave unsatisfactory wear, particularly in modern superheater locomotives, and the tendency has been toward a harder and stronger iron.

At the request of the U. S. Railroad Administration the Bureau of Standards has investigated the mechanical, chemical and microscopical properties of a number of packing rings furnished with service-mileage records, as well as arbitration-test bars, chill-test specimens, and miscellaneous samples from different manufacturers. All of this material was cast iron such as is used for the various cylinder parts. At the same time a review was made of the previous work and specifications on this subject, to ascertain as far as possible the practices of the different foundries and to suggest such revision of existing specifications as would be warranted by the results of the present and of earlier investigations.

The results of the tests are to be published in Technologic Paper No. 172 of the Bureau of Standards, by C. H. Strand, associate physicist.

Conclusions are drawn and recommendations made as follows:

1. On the basis of tests made by inspectors of the U. S. Railroad Administration and this bureau, which were substantially in agreement, it is concluded that air furnace or so-called "gun iron" is more uniform in character and on the average of somewhat better mechanical properties than cupola

iron. The latter, however, often equals or even excels in mechanical properties the specimens of air-furnace iron tested in this investigation. The sulphur content of the air-furnace irons examined seldom exceed 0.06 per cent, while the cupola irons varied in sulphur content from 0.10 to 0.17 per cent.

2. The findings of the American Railway Master Mechanics' Association with respect to correlation of laboratory and service tests are confirmed in the present investigation. It was impossible, except in a very general way, to find any correlation between the quality of the iron as developed by laboratory tests and the mileage obtained in service. This is explained by the fact that many other factors besides the quality of the iron enter into consideration in the service results, namely, design, lubrication, method of handling the locomotive, topography of the country, character of water used in locomotive, etc. The ring from foundry B, which gave the exceptionally good service of 93,000 miles, showed no unusual properties in laboratory tests. It is for the reasons cited above that the conclusions and recommendations of this paper are based essentially upon laboratory tests.

3. The present specifications of the American Railway Master Mechanics' Association are somewhat lax in the requirements for mechanical properties. It is recommended that the transverse strength requirements of the 1¼-inch

arbitration bar be increased from 3,200 to 3,500 lb. for castings one-half of an inch or less in thickness, and from 3,500 to 3,800 lb. for castings over one-half of an inch in thickness. It is further recommended that the minimum deflection requirements for both cases be increased from 0.09 to 0.11 inch. The division line of the casting thickness is changed from five-eighths of an inch of the American Railway Master Mechanics' Association, to one-half of an inch in order to conform to the recognized standards of the American Society for Testing Materials.

4. It is preferable to leave the chemical composition and the melting process used to the manufacturer, depending for the most part on the mechanical tests, and of these primarily upon the transverse test. The existing specifications allow a maximum of 0.70 per cent phosphorus and 0.12 per cent sulphur; there are no developments in this investigation which would warrant a revision of the maximum permissible amounts of these elements.

Acknowledgment is given to Capt. S. N. Petrenko and T. W. Greene for the mechanical tests and also to S. Epstein for the metallographic work. The co-operation of the chemistry division of the Bureau of Standards in making the chemical analyses is likewise acknowledged.

The paper also includes a proposed specification for cast iron cylinder parts.

EQUIPMENT ORDERS IN THE FIRST NINE MONTHS OF 1920.—The Class I railroads of the United States ordered in the first nine months of 1920, 1,403 locomotives, 40,254 freight cars and 814 passenger cars. Canadian roads ordered 154 locomotives, 10,773 freight cars and 174 passenger cars. The total orders for freight cars placed in the United States amounted to 57,172; in addition to the 40,254 placed by Class I roads, there were also 256 cars ordered by other roads and 16,662 by private car lines and industrials.

URANIUM AS A STRUCTURAL STEEL ALLOY

Characteristics Apparently Suitable for a Wide Range of Application to Locomotive Parts

BY HUGH S. FOOTE

Metallurgist, Standard Chemical Company, Pittsburgh, Pa.

DURING the past decade the volume of alloy steel production has been quadrupled and the automotive and aircraft industries have made wonderful strides in development. The progress of these industries is very intimately connected with the betterment of alloy steels. With the development of alloy steels of greater strength, of improved capacity to sustain sudden loads, and with a greater resistance to vibration and wear, more weight may be eliminated, thus contributing to greater commercial economy in many ways. A steel possessing such capabilities should also have the following qualifications: A competitive cost price; simplicity in heat treating processes, and simple composition. The greater the number of alloys present in the steel, the more independent variables there are to influence its properties; while the fewer the alloys, the more simplified is the steel practice, the greater the purchasing efficiency, and the less inspection and routine chemical analysis.

The development of uranium steel has produced a type which promises to fulfill these requirements. In addition, uranium steels are not embrittled by high temperatures, nor do they show a tendency to crack under severe quenching; and because of the depth hardening effect of uranium, they are less liable to warp in heat treatment. This means economy through less regulation and fewer rejections of the steel.

The Influence of Uranium

To date, the industrial application of uranium has been confined to high speed tool steel. The evidence would seem to indicate that uranium promotes the formation of a complex carbide which is more readily soluble in gamma iron than the usual carbide of high speed tool steel. Since the cutting property of this type of steel is dependent upon the dissolved carbides, the function of uranium is in part to increase the cutting qualities. Inasmuch as uranium also belongs to the same group or family as tungsten, it may be assumed logically that uranium also tends to increase the red-hardness.

The experimental work on the application of uranium to carbon and simple alloy steels has been carried on for four years. Uranium is one of the most powerful elements yet discovered for alloying with steel, and the most active in making steel respond to heat treatment. Microscopic examination shows that the uranium in structural steel probably combines with the cementite to form a double carbide of iron and uranium. It emphasizes the characteristics of the cementite to a greater degree than other carbide forming alloys and is effective with a lesser loss of ductility and in a wider range of temperature limits in its heat treatment than other alloys.

Dr. George K. Burgess, of the Bureau of Standards, states that unlike zirconium and titanium, uranium appears to enter into solution in steel, that is, it is a true alloying addition. In the normalized specimens a distinct martensitic and troostitic pattern is present, which is undoubtedly due to the presence of the uranium in solid solution, as otherwise the structure would be found to consist of granular pearlite and ferrite.

The introduction of uranium into steel in amounts over .60 per cent imparts no properties which are not obtainable

with a lower percentage contents. This is illustrated by the following analyses:

Chemical composition, per cent,		Elastic limit, lb.	Tensile strength, lb.	El. in 2 in., per cent	Red. area, per cent	Brinell
Carbon	Uranium	85,700	125,200	18	41.6	241
.46	3.02	81,900	116,700	21.5	54.2	231
.45	1.40	97,600	144,030	17.0	61.8	293
.44	.19					

Heat treatment in each case: 1,500 deg. F., quenched in oil and drawn to 570 deg. F.

Uranium is not limited by carbon content for its effects. This is illustrated by an example in which the addition of .56 per cent uranium to a .19 per cent carbon steel gave an elastic limit of 110,000 lb., a tensile strength of 140,700 lb., with an elongation in two inches of 11.5 per cent, a reduction of area of 52 per cent and a Brinell hardness of 235, when quenched in water from 1,560 deg. F., and drawn back to 480 deg. F. Furthermore, uranium does not need the effect of an intensifier, such as is produced by chromium when used with nickel or vanadium to bring out its full influence. This point is illustrated by the comparison shown in the accompanying table.

COMPARISON OF CHROME-VANADIUM, CHROME-NICKEL AND CARBON-URANIUM STEELS OF MEDIUM CARBON CONTENTS

Chemical Composition

"A"—C, .54 per cent; U, .27 per cent; Mn, .61 per cent.
 "B"—C, .50 per cent; Cr, 1.06 per cent; V, .20 per cent.
 "C"—C, .50 per cent; Cr, 1.10 per cent; Ni, 1.75 per cent; Mn, .45 per cent.

Physical Properties

	Elastic limit, lb.	Tensile strength, lb.	El. in 2 in., per cent	Red. area, per cent	Brinell	Merit number
"A".....	226,000	248,800	10.0	35.4	477	2,488,000
"B".....	217,300	227,000	10.0	35.5	402	2,270,000
"C".....	200,000	215,000	8.0	35.0	400	1,720,000

Comparative static and dynamic tests were made between the usual bearing steel and uranium steel. The bearing steel contained 1.01 per cent carbon, 1.68 per cent chromium, .18 per cent vanadium and .34 manganese, while the uranium steel had a carbon content of .63 per cent, .40 per cent

STATIC AND DYNAMIC TESTS OF URANIUM AND CHROME-VANADIUM STEELS

Uranium Steel

163,500	172,840	11.5	30.8	364	
Charpy impact = 53 ft. per sq. in.					
Alternating impact = 498 and 412 blows.					750 deg. F.

uranium and .50 per cent manganese. Comparisons of dynamic and static tests of these steels after being hardened and drawn back through a considerable range of temperatures are shown in one of the tables. Comparing the tension tests

either on the basis of Brinell hardness or on that of static strength, it is seen that the superiority lies with uranium steel. The ductility of the uranium steel, particularly at the lower drawing temperatures, is remarkable. This property is utilized in obtaining the merit number by multiplying the tensile strength of the material by its elongation, thus giving a relative idea of the amount of work that must be expended upon the material to break it. In other words, its strength must be overcome through a distance represented by its ductility before it may be broken. The dynamic tests show that the uranium steel possesses a greater resistance to shock and vibratory stresses conducive to fatigue than does the high carbon chrome steel.

Heat Treatment

The heat treatment of steel is one of the most important operations to which it is subjected, and to obtain the highest physical properties by this means, it is necessary to have accurate knowledge of the critical or transformation points. Although the changes due to heat treatment are governed by definite laws, the same treatment cannot be applied to all steels with satisfactory results, for each type of steel responds best to its own characteristic temperature.

Up to a content of two per cent, uranium has no marked influence on the critical or transformation temperatures. The majority of determinations place the Ac_1 (decalescent) point in the interval of 1,365 deg. F. to 1,380 deg. F. and in steels with a uranium content under two per cent the beginning of the Ar_1 (recalescent) point is between 1,255 deg. F. and 1,275 deg. F. Leeds & Northrup, in carbon steels (carbon .20 per cent to .60 per cent) place the Ac_1 point at 1,367 deg. F. and the Ar_1 point between 1,275 deg. F. and 1,259 deg. F.

The quenching temperatures of uranium steels do not differ radically from those of carbon steels. In general, the heating for hardening should be slow, uniform, thorough and to the lowest temperature which will give the desired results. Contrary to the characteristics of most alloy steels of a carbide nature, those containing uranium are not inherently sensitive to prolonged heating or severe quenching.

In order to obtain the superior dynamic qualities and at the same time avoid the large grain size caused by the high temperature annealing it has been our practice to normalize uranium steels. The forged or rolled material is slowly and thoroughly heated from 1,650 deg. F. to 1,700 deg. F., cooled in the air until black, then annealed at a temperature which will give the desired softness or physical properties. The normalizing accomplishes the following purposes: First, the high temperature overcomes any sluggishness on the part of the uranium toward going into solid solution. Second, all strains caused by previous operations are eradicated while the crystalline structure is refined, and third, the steel is in the best possible condition for heat treatment.

The function of the quenching medium is to remove the heat from properly heated steel with sufficient rapidity to enable it to retain the martensitic constituent. In this connection it may be said of uranium steels that they do not give a tendency to crack when quenched in water as do steels alloyed with chromium.

FOURTEEN POINTS OF INDUSTRIAL RELATIONS

In a recent article in the Iron Trade Review, Robert E. Newcomb, of the Worthington Pump & Machinery Corporation, set forth the disadvantages of employee representation in the management of industry. Mr. Newcomb stated that the soviet form of control would probably not be a permanent success and offered as a solution of the industrial problem the following basis for relations between employer and employee:

1. The policy of directors and managers must be one of

human interest in the welfare of the employee for the good it does the man.

2. Educate present foremen to the policy of the management by frequent individual conferences, as well as group conferences with the foremen. This is frequently neglected but of great importance, as the foreman is the key to the industrial situation and frequently unintentionally throws sand into the wheels of industrial harmony.

3. Use greater care in the selection of executives, especially the foremen, taking only those of high moral character and of broad human interest and train them to share responsibilities with employee and management.

4. Train an employee thoroughly with respect to his trade and in an unselfish way, thus fitting him for promotion and inspiring him with an intent to rise above his existing condition by his conscientious efforts and industry.

5. Scientifically organize and control the management of the establishment. Rule it with a firm, efficient, economic and just power, and human love.

6. Establish a wage system which will appeal to the individual and inspire him to his best efforts.

7. Encourage executives, and especially foremen, to have a friendly interest in the personal affairs of the employees.

8. Be prepared to advise an employee with reference to legal matters, medical attention, how and when to borrow money for building purposes, how and where to invest money in safe conservative investments.

9. Where the corporation is large enough, legal and medical advice and investments and loans should be handled by experts. In other cases the employment officer and the superintendent should know to what lawyers and doctors and banks to direct their employees to get the necessary advice.

10. Help the employee to acquire a home by making such arrangements with the bank as will enable him to procure funds. The company can usually take out a second mortgage which the bank will carry with the company's endorsement at no expense and small risk to the company. The home owner acquires a proprietary interest in his property and naturally acquires the instinct of a property owner.

11. For those single men and others who do not wish to acquire a home, provide means for investing surplus funds, such as conveniences for making deposits in the savings bank at the rate of so much per week, a method corresponding to the deductions for the Liberty loan.

12. Also provide some scheme whereby the employee can purchase stock in the corporation, weekly payments being taken from his wages.

13. Encourage sick and accident insurance, and if possible provide old age pensions. These should be provided by state legislation, but may be advantageously handled through private companies until such legislation is passed. These advantages should not be provided entirely free of cost to the employee, but may be provided in part by the corporation for the purpose of encouraging the employee to look out for the future.

14. Avoid anything and everything which has an indication of paternalism or charity. Executives should be democratic and take pains to recognize employees on the street and in all public places. Do not have or permit the executives to have too much official dignity; insist, however, that they maintain natural dignity.

FUEL SAVING IN FRANCE.—Following a vote of the Paris Municipality, the Prefect of the Seine Department has opened a competition, for which 100,000 francs have been set apart for distribution in prizes, with a view to arriving at practical means for attenuating the fuel crisis. The competition is to bear on the apparatus, products, or processes which can come into use either from the commencement of next winter or at a later date. When the competitors have been classified by the deciding jury, an exhibition is to be held of the schemes which are likely to give immediate results.—*L'Electricien*.

THE MECHANICAL STOKER AND FUEL ECONOMY

Analysis of Some Conditions Obtaining in the Locomotive Firebox Provided with Stoker Operation

BY F. P. ROESCH
Standard Stoker Company

THERE is no question that the ever rising cost of coal, together with the presumably increased amount necessary to produce a gross ton mile, when comparing hand with stoker firing, has a material influence on stoker applications, not only on new, but to existing power on which the application might be warranted, in order to obtain the full potential power output from the locomotive in question.

Past experience, as well as repeated tests, have amply demonstrated that this opinion, apparently well founded, cannot be gainsaid. It is equally true, however, that the conditions surrounding the various experiences and tests have not been fully considered in all their phases.

It would appear that the mechanical stoker is not being applied through any intrinsic worth or capacity increasing possibilities essentially its own, but because either the new locomotives are becoming so large as to preclude the possibility of successful hand firing when worked to their capacity, or to the fact that the class of labor from which we formerly drew our enginemen is seeking occupation in fields where the work is less arduous.

In discussing stoker possibilities, the following are the arguments generally used against their application:

First—The engines do not steam as well when stoker fired.

Second—Stokers increase the delay at cinder pits, owing to their tendency to clinker fires.

Third—They increase the cost of maintenance per locomotive mile.

Fourth—They burn more coal per 1,000 ton-miles than the same locomotive hand fired.

I believe an impartial analysis of the foregoing objections will prove that none present well founded objections or impose conditions that cannot be overcome.

Stokers Not Responsible for Non-Steamng or Clinkering

The function of the modern stoker is to prepare the coal, (i. e., crush it to firing size), convey it to the firebox and distribute it over the grate surface. As all stokers handling mine run coal perform the first and second operations automatically, the steaming of the locomotive can only be effected by that part of the operation depending upon the fireman, namely, the amount of coal supplied to the firebox and its distribution. As the amount can be varied to suit the requirements, and as the modern stoker has a flexibility of distribution equal to that possible with the most expert scoop manipulation, it follows that if given the same attention as to quantity of fuel supplied and distribution over the grates, the introduction of fuel manually or mechanically should in no manner affect the steam generation.

How then can we consistently attribute the non-steaming of any locomotive to the stoker? Any analysis of such a charge will invariably point to the human agent, the physical condition of the locomotive or the characteristics of the fuel. And yet the writer knows of many instances, notably some where the stacks of a recent consignment of locomotives were from 1 to 3½ inches out of line with the exhaust nozzle, and where the failure of the locomotives to steam freely was attributed solely to the mechanical stoker.

Clinkers are formed by the fusion of iron pyrites, sulphur, etc., at low temperatures. It follows, therefore, that clinkers are primarily a characteristic of the fuel, aided in their formation, of course, by the manner in which it is handled. The

charge has been made that clinker formation is aggravated by the introduction of steam jets over the fire. On the contrary, it has been proven that the moderate use of small steam jets are beneficial, as they are a material aid in the thorough mixing of the gases distilled from the fuel, a prime essential in perfect combustion.

Stoker Maintenance and Fuel Consumption

There is no question but that the application of any auxiliary appliance to any locomotive will increase the cost of maintenance. This applies with equal force to the air brake, the lubricator or any other adjunct, if the cost is simply based on the cost per locomotive mile; however, if the cost is based on the true barometer of locomotive operation, viz., *cost per ton mile per hour*, not only the stoker, but practically many other appliances can show a clean bill of health. The inconsistency of present methods of compiling statistics relating to locomotive performance was very forcibly brought out by Robert Quayle, of the C. & N. W., at the recent convention of the International Railway Fuel Association.

The fuel consumption of any locomotive depends altogether on the following factors: *First*, the characteristics of the fuel (i. e., the proportion of combustible to non-combustible or ash). *Second*, the condition of the boiler and its capacity to transfer heat. *Third*, the condition of the locomotive engine, insofar as economical steam utilization is concerned. *Fourth*, the service in which the locomotive is engaged, and last, but not least, the men in charge, or the manner in which the locomotive is handled and fired.

With all of the above factors equal, the only added increase in fuel consumption that can be attributed to the stoker is the additional weight to be hauled—each extra pound of weight requires a proportionate power output, regardless of whether the added weight is on or behind the locomotive—the steam necessary to crush, convey and distribute the fuel, the increase in spark losses and the losses due to improper combustion. The amount of fuel required to haul the stoker can be readily determined from the daily performance sheets, as, for instance, if this data shows a consumption of, say, 210 lbs. of coal per 1,000 ton-miles, then the weight of the stoker, multiplied by the coal consumption per mile, will give the coal chargeable to this item.

The fuel required to operate the stoker must, of course, be determined from the steam consumption. This by test for the engine and calculation for the distributor consumption, has been found to vary from 0.5 per cent to 2 per cent of the steam generated by the boiler, the difference depending on the type of stoker used. (See report of Pennsylvania Railway tests in the *Railway Mechanical Engineer* of April, 1920, page 199.) This factor holds good under practically all conditions, as where a greater demand is made on the boiler, a correspondingly increased demand is made on the stoker, and vice versa.

Spark Losses Due to Mechanical Stokers

That under some conditions there should be an increased spark loss with stoker fired locomotives is clearly evident when we consider the fact that spark losses are almost directly proportionate to the amount of slack contained in the coal and the height at which it is introduced into the furnace. As with the modern stoker, the coal is all passed through a crusher

before it enters the firebox, it follows that the slack must necessarily be increased over that obtaining with hand firing when the large lumps are simply cracked with the coal pick, if they are broken at all. While the slack content is a vital factor, yet the height at which the fuel is introduced is even more so, tests having shown that with the older type of stoker having a distributor located above the fire-door, the spark losses were reduced 30 per cent by cutting out or blanking this opening.

The spark loss, however, can be materially reduced, and with some types of stoker, practically eliminated, by simply increasing the length of the brick arch. Such an increase will not only reduce the spark loss, but improve the combustion, increase the firebox temperature, reduce the tendency toward stopped up tubes, increase the superheat, etc. True, there have been objections urged against the long arch, but principally by the firemen, on the ground that a long arch made the engines too hot at the door. However, with the application of the stoker, this objection loses its weight, as the fireman is no longer exposed to the furnace heat, and it might be well to note that as a long arch increases the heat at the door, it must follow that it increases the heat at the door sheet, thereby increasing the furnace efficiency.

Combustion in the locomotive firebox depends first upon the presence of the correct amount of air, and second on the thorough mixture of the air with the distilled gases. In the locomotive firebox the air is usually admitted through the grates and the fuel bed. Given a coal running high in non-combustibles, or an imperfect distribution of fuel, the admission of air becomes a very uncertain and in a measure uncontrollable quantity.

As a matter of fact, we know but little of what actually takes place in the locomotive firebox under the varying conditions of service. Our draft gages can only be inserted to a limited distance, hence can only register a local condition (i. e., the vacuum obtaining in the immediate vicinity of the opening). On the data so obtained we base our theories as to what is going on in other parts of the firebox. Aviators have found what they term "air pockets" or strata of air of lesser density than the surrounding atmosphere. Is it not reasonable, therefore, to assume that if such differences in pressure can occur in a practically undisturbed medium as compared with firebox conditions, that we have disturbances, air pockets and high and low pressures in the firebox likewise? And further, granting this hypothesis, does it not follow that these conditions vitally affect the efficiency of combustion?

Air Supply a Vital Factor

Tests conducted by the Bureau of Standards clearly demonstrate that where the air was introduced through the fuel bed alone, there was practically no free oxygen at a point three inches above the incandescent coals, indicating beyond the question of a doubt that the amount of air so admitted was insufficient. Again, many can bear witness to the fact that it is frequently necessary to hold the fire-door partly open, and with some coals, entirely so, to make up for the deficiency. With a locomotive hand fired, the needed amount is passed in through the opened door, not very efficiently, perhaps, but introduced nevertheless. In stoker firing the door is only opened when the fireman wants to observe the condition of the fire; consequently, practically all air must be introduced elsewhere. Where no other provision is made, the only point of entrance is through the grates and fuel bed; therefore, if the distribution is not uniform or the fuel bed is too thick, imperfect combustion and the attendant fuel loss is bound to ensue.

The necessity for an increased supply of air was fully recognized by F. F. Gaines and others years ago, when efforts were made to introduce the hollow arch on hand fired locomotives. If that was the case at that time and with that

type of power, surely the necessity is doubly emphasized with modern power stoker fired. Therefore, is this not a vital point to be considered both by stoker manufacturers and railway mechanical men? Prof. Endsley echoed the thought at the 1920 convention of A. R. A., Section III, Mechanical, when he recommended the introduction of additional air in finely divided streamlets. His argument is too sound to warrant any effort at contradiction.

In the discussion of a report on mechanical locomotive stokers, the consensus of opinions expressed, as well as the results obtained at the Altoona testing plant, indicated that under moderate rates of combustion, hand firing was more economical than stoker firing, but at higher rates the stoker gradually approached expert hand firing in efficiency. The answer can be found in the preceding paragraphs, but to save repetition, we can say, at moderate rates the fireman has ample time to so scatter the coal as to maintain a practically level fuel bed, and, as the time between fires is more infrequent, a lesser amount of air is introduced through the fire-door; while at the higher rates the continued opening of the door admits too much cold air, thereby retarding combustion, and the haste at which it is necessary to introduce the coal precludes effective scattering. If, however, with the stoker the same uniform spreading of the coal had been possible as with hand firing, and some provision had been made to introduce the additional air required above the fire, there is no question but that at the lowest rate the fuel consumption would be practically the same in both instances with no showing in favor of hand firing.

The entire subject is worth the careful study of all who are concerned in reducing the cost of locomotive operation, as with the ever increasing cost of fuel, no item that will in any way reduce the amount required per 1,000 ton-miles per hour is negligible. The stoker is here to stay, and its use will gradually be extended. Locomotives will continue to be operated from light to maximum capacity. The same amount of coal can be made to produce the same unit of work under proper conditions, regardless of whether it is placed in the firebox manually or mechanically.

FREIGHT CAR PRODUCTION—EIGHT MONTHS' FIGURES.—Figures of production reported by 23 leading car building companies associated with the Railway Car Manufacturers' Association show that the car building industry in August was working at a slightly higher percentage of capacity than in July. The number of new freight cars delivered in August totaled 3,056 for domestic service and 1,184 for export, as compared with 2,583 and 380, respectively, in July. The deliveries of passenger cars totaled 21 for domestic service and 13 for export. Car repairs totaled 2,818, as against 2,491 in July. At the end of August there were 49,442 freight cars for domestic service on order and undelivered, 861 passenger cars and 27,031 heavy repairs.

COST OF RAILROAD FUEL.—The increase in the cost of coal purchased by railways, in July, 1920, as compared with the cost in July, 1919, is shown in a compilation made by the Interstate Commerce Commission from reports received from 159 railroads. In July, 1920, these railroads purchased 9,627,491 net tons of bituminous contract coal at an average price at the mines of \$3.24 per net ton, as compared with 8,880,021 net tons in July, 1919, at an average cost of \$2.47. They also purchased 1,518,444 tons of spot coal at an average price of \$6.01, as compared with 476,758 tons last July at an average of \$2.40, an average of \$3.58 for contract coal, as compared with \$2.42 last year, and \$8.36 for spot coal as compared with \$2.51, while industries paid \$4.40 for contract coal and \$8.44 for spot coal, as compared with \$2.13 and \$2.04 last year. For anthracite coal the railroads paid an average of \$4.23 for contract coal and \$4.50 for spot coal, as compared with \$3.45 and \$3.04 last year. In the New England district the average was \$7.14 for contract coal and \$10.54 for spot coal as compared with \$5.46 and \$5.33 last year. The utilities paid \$4.61 and \$6.28 as compared with \$3.19 and \$5.15 last year, and the industries \$2.48 and \$4.85 as compared with \$2.76 and \$3.25.

BEST METHOD OF HANDLING FREIGHT TRAINS*

In order to handle freight trains efficiently and economically, it will be necessary to take into consideration the locomotive which hauls the train, as well as all other equipment used in doing the work; the locomotive must be put in the best possible condition before leaving the shop, so that it can handle the train efficiently and economically. With the eight-hour day and time and half time for overtime, the locomotive must haul the allotted tonnage over the division in as short a time as possible. This cannot be done with a 50 per cent engine.

CONDITION OF CARS

Cars should be in good condition before being sent out in a train to avoid delays due to accidents on the road. In order to do this, cars should be properly inspected and repairs made, or the cars switched out. It is necessary to have receiving yards laid out so that the work can be done quickly, and facilities should be provided to take care of all the details of inspection at one time.

All trains when stopped in receiving yards should have couplers stretched from engine to caboose; this can be done by having some hand brakes set on the rear of the train and have the engine pull the slack out. It is better to delay a train in the yard for inspection and repairs than it is to have it delayed out on the road. While in the yard only one track is blocked and other trains can pass on some other track, but on the road, when stopped by an accident, other following and opposing trains, in charge of crews making overtime, are blocked. When a train is delayed in the yard there is no crew time to be considered.

The same can be said of hot boxes. With the long and heavy trains that are being handled today, when you have to set out a hot box about 75 or 90 cars from the engine, it takes time and very often results in damage to other cars in the train.

All trains when stopped in the yards before the engine is cut loose should have the air brakes applied with a full service application, so that the air inspectors can go over the train and mark up the piston travel and defective brakes or brakes that are cut out, so that cars can be given the proper attention before being sent out of the dispatching yard. If the defect is such that the car must be shopped, it can be switched out while switching the train and then it will not have to be done after the train is made up, which very often delays the crew at the start of the trip and causes overtime.

All despatching yards should be provided with a yard air brake testing plant, and as soon as the train is switched the air should be coupled up from the yard plant and brake pipe leakage taken up, piston travel adjusted and retaining valves tested.

When the train and engine crews arrive, all that they will have to do is to couple the engine to the train and charge the brake pipe to the maximum pressure carried and test to comply with the rules in effect on the road. It has been found when trains have been worked properly by air men, all that is necessary for the crew to do is to know that the brakes will apply and release at the front and rear end of the train before leaving the yard.

HANDLING FREIGHT TRAINS ON LEVEL DIVISIONS

The trains on level divisions should consist of all through loads as much as possible, and the train should consist of as much tonnage as the locomotive can handle and make an average speed of at least 14 miles an hour. If it is necessary to fill out a train with cars for intermediate points or

to give the train local cars, they should be switched on the front part of the train in station order, so that only the cars to be set off will have to be handled.

With the long heavy trains that are being handled at the present time, after a train has started out of the yard it should be kept moving, for the stopping and starting is what causes delays and damage to equipment.

The train should not be stopped for coal over the division and should be stopped for water as few times as is possible. In making stops for coal and water, the engineer should be very careful not to make spot stops with a heavy freight train.

All long and heavy freight trains should be stopped with one application of the air brakes and the engineer should endeavor to keep the slack bunched from the front end. This can best be done by making the initial reduction just sufficiently heavy to run the slack in and follow up with light reductions until the train is stopped. In order to keep the front end from running out, the engineer should make a reduction of about eight or ten pounds about 60 ft. before coming to a full stop. This is to keep the air brakes applying stronger on the front end to hold the slack in and leave the brake applied on the train when the engine is cut off. Engines so equipped give splendid performances both from capacity and fuel economy standpoints.

In starting a train with one engine, the engineer must be very careful until he has pulled all of the slack out of the draw-bars before fully opening the throttle. There is about 9 to 12 in. of slack between the cars, and this will increase on the front end in starting, due to the compression of the draw-bar springs and the dead weight of the cars that have not been started. The engine will move about 60 to 70 ft. on a 70 to 75-car train before the rear end moves on the level and more on an ascending grade.

In starting a two-engine train on level roads, the lead engine only should start to pull and take up all the slack that it can. Then the second engine should start to pull by opening the throttle gradually until the entire train is started, then increase the throttle opening as may be required. The train should be moved at a slow rate of speed for a distance of just one train length, so that the trainmen can look over the train and in case any brakes are sticking they can be released. Very often it is possible to locate a defective coupler in the train when it would not be noticed at any other time, except when the train is stretched out so far. This will occur at times when couplers are badly worn and the draft spring broken or worn.

DESPATCHING TRAINS FROM YARDS

Where the yard is equipped with an air-brake testing plant, see that the brake pipe leakage is below standard allowance and all other work done before the train is ordered to leave the yard, so that when the road engine arrives in the yard it can be coupled onto the train at once and make the road test.

The success of the trip greatly depends on the start out of the yard. The importance of having the train ready to move by the time it is called is readily seen, for one hour delay at the start means overtime on the eight-hour day and 12½ mile an hour basis.

The train despatcher must not stop trains unnecessarily, for an avoidable stop made by a heavy freight train means a loss of time in stopping, then getting the flagman in and starting, and very often the train is parted in trying to start, due to a broken coupler or coupler slipping by which might not have occurred if the train had not been stopped. There is also an excessive amount of fuel consumed by the extra stops and in trying to make up some of the time lost by the stops.

There is no economy in loading a freight train so that it

* From a paper presented at the convention of the Traveling Engineers' Association.

is unable to get over the division without making overtime.

HANDLING FREIGHT TRAINS ON MOUNTAIN DIVISIONS

On divisions where the grades are heavy and it is the practice of using one or more helpers on the ascending grades, it is important that no weak cars be used in heavy tonnage freight trains, if possible to avoid it. With the Mallet and Santa Fe type locomotives having tractive efforts of from 70,000 lb. to 105,000 lb. cars with weak end and center sills or weak couplers are very dangerous to handle in trains of this kind. There should be instructions given to all yard masters and car inspectors that cars that appear to be old or of weak construction should be switched out of heavy trains where helpers are used and placed in a train to be run without a helper or a train hauling light tonnage.

It has been demonstrated from time to time that it is not necessary to use hand brakes on freight trains on descending grades any more than it is on passenger trains, when the equipment is properly maintained. With the ordinary air brake, if properly maintained and manipulated, it is possible to handle freight trains on heavy descending grades with the air brakes with a greater degree of safety than with the use of hand brakes, because it is possible to do the braking more uniformly throughout the train and to maintain a more uniform rate of speed.

According to the information obtained from the different roads, the permissible brake pipe leakage on trains of 30 to 100 cars varies from five to eight pounds per minute, which is about all the air feed valve will take care of and about the limit of leakage with which an engineer can do a good job of braking. It has been found by actual tests on heavy mountain grades that it is very difficult to release the brakes on the rear end of 75 to 90 cars with a brake pipe leakage of over seven pounds, and if the brakes are not released on the rear end after each application the tendency for jerking the train and excessive wheel heating is greater.

Some roads are handling trains on level tracks as well as on heavy mountain grades with electric power, and some other roads are figuring very strongly on electrification. While this method of operation applies only to a few roads, we are of the opinion that more roads will take up the matter of electrification in the near future from the fact that with the electric locomotive the terminal delays can be reduced considerably, as well as delays in stopping for water and coal, and it has been demonstrated that an electric locomotive can be run over three divisions of over 100 miles each, by changing crews, without any delays to the locomotive. This would indicate a high point of efficiency from the fact that it could be a no-stop operation from one end of the division to the other. This would eliminate the pulling out of draw-bars and damage to equipment due to starting and stopping. It would also reduce the cost of brake shoes and other brake equipment.

On heavy grades the speed of the train is controlled while descending, by regeneration, but it must be understood that by regeneration the speed of the train is only held under control and it will be necessary to use the air brakes to stop.

The report was signed by Frederick Kerby (B. & O.), chairman; M. O. Davis (A., T. & S. F.), M. A. Daly (Nor. Pac.), P. G. Leonard (G. H. & S. A.) and Malon Laquay (Grand Trunk).

Discussion

The greater part of the discussion was devoted to the best methods of making water stops with long freight trains. The practice of stopping short of the water crane, then moving the train up slowly to the final stop, was commented on favorably by a number of the members. Where the more common practice of cutting off the engine is followed, it requires from 20 minutes to 1½ hours to release and recharge the brakes after the engine has been recoupled to the train,

the time depending on the amount of brake pipe leakage. Furthermore, some of the members have found that an actual reduction in the amount of damage to draft gears has been effected by the practice of moving the whole train slowly to the final stop. The reason given for this was that stuck brakes often follow the recharging of the train. It was evident that the roads where this practice has been adopted are comparatively level and handle trains ranging from 3,000 tons to 4,000 tons. The opinion was that where unusually heavy trains are handled or where grade conditions prevail the only safe rule to follow is to stop and cut the engine off before moving to the water tank.

The incoming test and the yard charging plant were favorably commented on. The yard charging plant saves from 1 to 1½ hours' crew time in getting away from terminals.

The effect of slack action has been found of more importance on electrified districts than it was when steam power was used. Where regenerative braking is used no trouble is experienced in making emergency applications of the air brakes on descending grades. But when ascending great care must be used to prevent pulling out drawbars. The practice which has been developed is to first apply the brakes, then shut off the power gradually to prevent the heavy run in of slack due to the higher braking power immediately developed at the front end of the train.

Referring to the statement in the report that freight trains can be handled on mountain grades with power brakes only, it was stated that in order to do this retainers must be put in good condition before descending the grades, and the greatest success cannot be attained unless all railroads maintain the brake equipment as the laws require. Otherwise, the mountain roads will be required to do an excessive amount of work to put the equipment in safe condition.

THE EFFECT OF SLACK WEDGES

A discussion on this topic was presented in a paper on the general subject of locomotive upkeep, prepared by a committee of which J. C. Brennan (N. Y. C.) was chairman. In the discussion which followed the reading of the paper several of the members dwelt on the fact that, aside from loose binders or thimble bolts, the cause for practically all failures of frames over the driving boxes is slack wedges. Some difficulty has been experienced in getting wedges properly adjusted in the roundhouse. Unless the locomotive is properly spotted the machinist is very likely to find it standing so that the wedges appear to be tight and he frequently reaches that conclusion when the wedges have been reported by the engineman to be set up. The Franklin self-adjusting wedge was favorably commented on by representatives of the railroads on which it has been applied, some of the members reporting a decided decrease in the number of broken frames on classes of locomotives now equipped with this device. These wedges have been run for six months without touching the adjustment but all of those who have had experience with them emphasize the necessity of keeping them lubricated. In some cases it is the practice for the inspector to oil the wedge a little before each trip.

The difficulty of securing proper attention to the usual type of wedges on engines in pooled service was mentioned. In pooled service the Canadian Pacific has developed the practice of giving each engineman a copy of the work report turned in by the man who last had the locomotive, as a means of developing a more intelligent interest in the condition of locomotives on the part of the crew. It was also suggested that excellent results might be obtained if each engine man were given a copy of his work report, showing the conditions actually found in the roundhouse. This would tend to correct habitually wrong diagnoses on the part of the enginemen.

General View of the East Buffalo Car Shop

N. Y. C. STEEL CAR SHOP AT EAST BUFFALO

**Capacity of Building with Latest Additions 236 Cars;
Overhead Cranes Eliminate Need for Material Tracks**

THE New York Central maintains at East Buffalo, New York, the largest freight car shop on the system and probably one of the largest in this country devoted primarily to the repairing of freight cars. The original shop erected in 1865 has been greatly enlarged, extensive additions having been built in 1910 and in 1919. At present the buildings have a capacity of 218 freight and 18 passenger cars while the adjoining repair tracks provide space for 170

in 1910, both of which are used for repairing wooden cars, and the new shop for steel car work built in 1919. The wooden car department covers an area of 275 ft. by 600 ft. while the steel shop is 275 ft. wide and 400 ft. long. Adjoining the erecting shop on the east side is a brick building 605 ft. long and 85 and 110 ft. wide in which are located the planing mill, machine shop, blacksmith shop and power house. The blacksmith shop is 85 ft. by 200 ft.; the ma-

Layout of Yards and Buildings at East Buffalo

freight and 12 passenger cars. The force employed under normal conditions comprises about 900 men in productive labor and 75 in the supervisory positions.

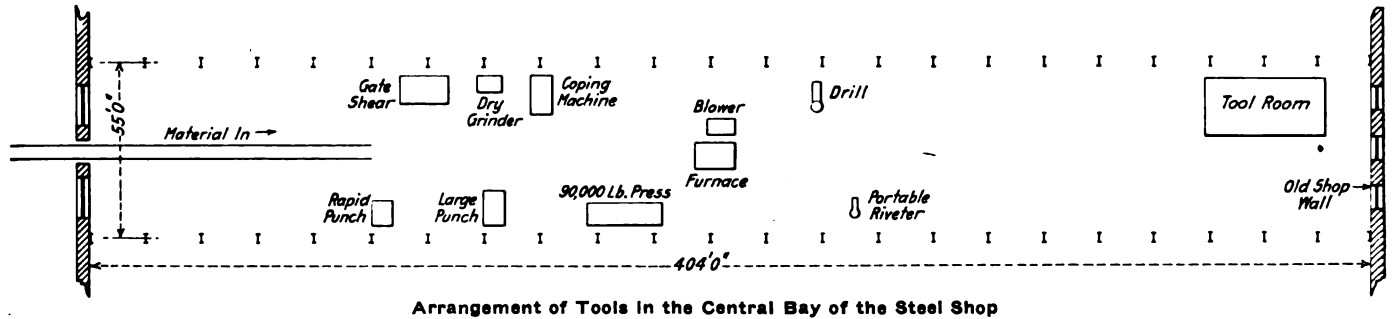

The East Buffalo car shop is located south of the main line of the New York Central and extends for more than a half mile alongside the freight yard. The layout centers around the erecting shop, which is 275 ft. wide and 1,000 ft. long, this building alone covering an area of 6.3 acres. The drawing below shows the three portions of the shop—the original erecting shop at the center with the addition built

chinese shop 85 ft. by 160 ft.; and the planing mill 110 ft. by 200 ft.

With this arrangement, an excellent routing of material is secured. The storehouses for castings, bar iron and finished material are at the south end of the shop, where they are most accessible to the blacksmith shop, while the lumber storage is easily reached from the north side of the planing mill. The machines are so arranged that the material is brought in at the ends of the shops and passes along without back movement for the successive operations and leaves the

last machine adjacent to the tracks leading to the erecting shop. At first thought it might seem that the location of the machine shop between the blacksmith shop and the planing mill would be a serious disadvantage but the amount of material handled in the machine shop is comparatively small with the exception of wheels and axles and tracks leading directly from the erecting shop are provided for handling these.

The power house occupies a space 45 ft. by 85 ft. between

the planing mill and the machine shop. The electric power used in the shop is purchased from outside sources and this small area is ample for the boilers, pumps and compressors. A separate building opposite the machine shop houses the transformers and the switchboards for the main circuits. The combined rating of the machines used in the shops is 2,378 h.p. Steam power which is used for the steam hammers, for heating and for the fire pumps is supplied by one 100 h.p. and two 200 h.p. locomotive type boilers. Two air compressors each of 1,500 cu. ft. capacity and driven by synchronous motors furnish compressed air for the shops.

The auxiliary buildings have been placed in convenient

transverse square monitors, is built with wood purlins laid on the steel trusses and covered with wood planks and plastic roofing.

The building is divided into five longitudinal bays which accommodate 13 tracks. The two west bays each have three tracks, the center or machine bay has a stub track, and east of this is another bay with three tracks. Each of these bays has a 10-ton traveling crane of 51 ft. 4-in. span with a two-ton auxiliary hoist. The extreme east bay has three tracks

but is not supplied with a crane. The lavatories and lockers are located on a balcony in the north end of this bay. The tracks are spaced 12 ft. 6 in. from the walls and 17 ft. 2 in. and 18 ft. between centers without any intermediate

One of the Erecting Bays

locations with respect to the main shop. A separate building is provided outside the planing mill for the resawing of second hand sills and other large timbers which can be worked over into smaller sizes. A paint shop 60 ft. wide by 360 ft. long with a paint mixing room adjacent is located at the south end of the shops. Owing to lack of space, this is used temporarily as a storehouse. The air brake department, electrical department and oil house are housed in separate buildings west of the main shop.

As the new steel car erecting shop represents the latest practice in construction and equipment, a more detailed description will be of interest. The shop is of brick and steel construction with concrete footings extending to a height of about six feet around the walls. Both the side and end walls have a large window area, ribbed glass and pivoted steel sash being used throughout. The roof, which has six

South End of New Steel Shop

tracks for handling material or working on trucks. The truck work is done while the trucks are rolled clear of the end of the car and material is transferred by the overhead cranes. This arrangement eliminates waste space in the

Looking Down Central Machine Bay

shop and increases the car capacity. A transfer track extends across the north end of the steel shop and provides a convenient means for transporting material from the machine shop or blacksmith shop to any of the tracks in the five bays.

The arrangement of the equipment in the steel car shop

is shown in one of the illustrations. Comparatively little equipment has been installed, as prior to the erection of the shop the standard material for system equipment was made at other points and this practice is still followed to some extent. The machine facilities are ample to take care of the cutting and shaping of any parts that the shop is called on to replace. One piece of equipment that is worthy of special mention is a 90,000 lb. geared power press which has a capacity for bending $\frac{3}{8}$ in. plates 10 ft. long.

While an extended description would be required to pre-

North End of the Erecting Shop, Planing Mill at the Left

sent a detailed account of the handling of work in the various departments, the list of machines shown herewith will serve to give an idea of the equipment needed for a shop of this size and the work that can be handled.

| Two band saws | One trimmer |
| Two horizontal boring machines | One saw sharpener |
| One horizontal angle boring machine | Two band saw filers |
| One vertical hollow chisel mortiser | One band saw setter |
| One horizontal mortiser | One band resaw stretcher |
| Two vertical sill tenoners | One band resaw lap grinder |
| One door and sash tenon machine | One planer knife grinder |
| Two moulding machines | One exhaust fan |
| One shaper | One band saw |
| One 4-side planer | One combination machine |
| One dimension planer | Electric motors, total 447½ hp. |

THE UPKEEP OF FREIGHT CAR EQUIPMENT*

BY J. W. SENER

Superintendent of Rolling Stock, New York Central Lines West

Those who are directly connected with and responsible for upkeep, care and maintenance can best appreciate the difficulties experienced in passing through the period of the war. At the present time during the reconstruction period, due to the shortage of labor and material and the increased traffic that is moving and the scarcity of freight equipment, we are facing perhaps a bigger problem than the one with which we had to contend during the great conflict for the period mentioned. During the past three or four years a limited amount of freight equipment having been purchased, it is necessary to maintain equipment that in normal times would have been retired. Therefore, in order to bring this subject before you the writer has confined himself to the most important parts and divided the subject as follows: Facilities, Material, Organization and Repairs.

FACILITIES

Facilities are the most important factor in car repairs next to labor. Up-to-date shops equipped with modern machinery and labor saving devices being limited to taking care of the equipment, it must be realized that a 100 per cent output cannot be had at all times; particularly is this true during the winter season. For obvious reasons the facilities for repairs have not kept pace with the increased equipment. This matter should be one of careful consideration with a view of increasing the facilities as quickly as possible.

ORGANIZATION

Shop organization is also a vital point and in order to produce the maximum output should consist of capable men. The most important of these are the shop superintendent or general foreman and his assistants. It is generally found that when the work is divided better results are obtained than to have the entire shop or shop yard covered by one man, as this practice makes the head of each division responsible. Junior supervisors should be educated to fill the position immediately ahead of them, so that in the absence of the foreman the work will proceed without loss of efficiency.

Men in supervisory capacities should be selected from the ranks when possible to do so. This practice is an incentive to others. They should be men of a good personality, broad minded in their dealings with men and thoroughly conversant with the details of the work.

Valuable results are obtained by holding monthly meetings of the supervisors, bringing them into closer touch with each other and the practice in vogue at their respective points. Meetings places should be changed from time to time giving to all an opportunity to observe the conditions at the different points. Much valuable information can thus be obtained that will result in saving and greater efficiency and due credit given to those who are responsible for same.

MATERIAL

The shortage of material is a handicap in production, often necessitating the substitution of one kind for another. Careful attention should be given to the use of material, that none is wasted and all is used to the best advantage. Full cooperation should be had between the mechanical and stores departments in the handling of material that no unnecessary delay be had in supplying material at hand. Advantage should be taken of the scrap dock, as much good material can be obtained. The necessary machinery and supervision to reclaim material should be furnished.

REPAIRS

Under this heading the writer has divided the subjects

*Abstracted from a paper presented before the Central Railway Club, September 10, 1920.

into three classes; viz: general repairs, light repairs and running repairs:

General Repairs: This refers to both wooden and steel equipment receiving heavy repairs or that are rebuilt, at which time due consideration should be given to the strengthening of all weak parts, the application of betterments, such as steel underframes, steel ends, improved doors and fixtures, etc., the thorough overhauling and modernizing of trucks, eliminating unnecessary parts and bolts, and providing safety irons to prevent brake beams falling down. After the completion of general repairs a final inspection should be made to know that all parts are in a serviceable condition before the car is released for service.

Under this heading, I want to call attention to the importance of a final inspection at the shops after cars receive heavy or general repairs. This should be done by very competent men who should go over each and every part carefully, see that all the movable parts of the brake equipment are in their place, especially cotter pins, which should be properly spread, and other small items likely to cause failures en route and which the car repairers overlook—in other words, when a car leaves the repair track it should be O. K. for service in every particular.

I also want to call attention to a lot of old and worn-out equipment now in service and which, in my opinion, ought to be retired. If you will look over some of this equipment when it is on your repair tracks you will find that a large percentage of the cars have been given temporary repairs to carry another load or two. It seems to me we are only wasting a lot of good money by trying to keep such equipment in service; besides, it is taking up a lot of valuable repair track room which could be utilized to better advantage.

Light Repairs: Under this caption the writer refers to cars repaired on the ordinary repair track and comprises such repairs as replacement of draft timbers, end sills, sill splices, parts of floors, parts of roof, doors and door fixtures, journal boxes, column castings, truck bolsters, side bearings, brake beams and connections, etc.

Cars on light repair tracks should be gone over carefully for defects which may send them to the heavy repair track and avoid making light repairs when the condition is such as to warrant general overhauling. In connection with the light repairs enumerated, attention should be given to the brake equipment doing all the necessary work to put the brake in first-class operative condition.

This is also an opportune time to inspect the car for worn parts, spreading of cotter keys, adjustments of the piston travel, seeing that proper connections and brake levers are applied and that the hand brake and uncoupling levers are efficient, and periodical packing of boxes. If this is done it would prevent the cutting out of cars when returned to service.

Running Repairs: This is generally understood as repairs made in the classification or train yards, either by inspectors or follow-up men. Right here I wish to impress upon everybody's mind the importance of having the little things taken care of which are at times neglected; that is, renewing short or broken knuckle pins, worn-out brake hangers and keys, bolts, the application and proper spreading of cotter keys, removal of worn brake shoe keys, application of missing parts and correction of Safety Appliance defects. At this time the hand brake should also receive a thorough inspection, journal boxes should be examined to see that brasses and keys are in place, that no sign of previous heating exists and that packing is in its proper place and that there is enough lubrication to run the car to its destination. By giving proper attention to cars in the classification yards which, of course, includes proper inspection, nearly all of our road delay and expense of setting out cars en route could be avoided.

Quite frequently we hear complaints from other depart-

ments on account of too much time being consumed in inspection and repairs in the classification yards. Inspection and light repairs are very necessary to insure the train going safely to its destination without delay. While the work should be done as quickly as possible we should insist upon proper time for inspection and repairs being allowed to accomplish this.

In conclusion the equipment department of the railroads is passing through and experiencing one of the most strenuous periods of its history. The demand that has been made upon it by the operating department of the railroad, due to the necessity for car equipment suitable for transportation purposes, has tended to make it necessary to use all classes of equipment to the maximum. We have been called upon to supply cars not for the commodities for which they were originally built, but for other classes of service for which they could be fitted by temporary repairs. As a consequence we now find ourselves with equipment on hand which will require some time to build up to its former usefulness, and this cannot be very well accomplished unless all railroads provide themselves with newly constructed equipment which can be placed in service to relieve equipment now running, to enable the cars to be brought into the shop and receive general repairs or overhauling which will fit them for the service for which they were originally built.

Discussion

F. W. Brazier (N. Y. C.) in a written discussion considered what could be done to reduce the cost of upkeep. He advocated more care in designing and getting comments from the foremen to do away with troublesome defects. More thought should be given to the type of equipment to avoid features that are expensive to maintain. As an example, he cited the elimination of unnecessary nuts and bolts and also mentioned improved door fastenings and key connected couplers as important improvements. Undue emphasis is often placed on reducing the first cost of equipment; but if the design of cars built years ago had received more attention, conditions would be better now.

C. H. Hogan (N. Y. C.) expressed the opinion that the most important matter at the present time is the question of organization. Handling labor is difficult and requires men of good judgment. The foremen should get close to their employees and study their character if they wish to secure a fair day's work.

F. C. Pickard (D. L. & W.) pointed out that the freight car situation is of extreme importance from the maintenance standpoint because 25 to 35 per cent more is spent for the maintenance of cars than for the upkeep of locomotives. He ascribed the present difficulty to the fact that during government control only 100,000 cars were purchased and practically none retired, while, normally, in this period the roads should have bought 550,000 cars and retired 600,000. While the bad-order cars on individual roads range from 6 to 15 per cent according to reports, Mr. Pickard expressed the opinion that a thorough inspection would show 30 to 40 per cent in bad order. Many cars now in service should be retired, particularly those with short draft timbers and with center sills cut to allow the bolster to pass through. He brought out that some roads have good facilities for repairing freight cars, while others are poorly equipped. To improve the bad-order situation, each road should contribute its share to maintaining the cars. He mentioned the damage to cars resulting from impact at excessive speeds as an important cause of damage to freight equipment.

J. E. Gordon (N. Y. C. & St. L.) mentioned the damage resulting from improper loading and G. J. Charlton (D. L. & W.) advocated the employment of inspectors at loading points to insure the observance of the loading rules. T. A. Ward (N. Y. C.) brought out the fact that 7 per cent of the loss and damage claims are due to defective equipment.

INTERCHANGE INSPECTORS AND CAR FOREMEN MEET

Discussion of Revision of Interchange Rules and Paper on Transfer and Adjustment of Lading

METHODS for increasing the efficiency of operation and expediting the movement of cars were the keynote subjects at the convention of the Chief Interchange Car Inspectors' and Car Foremen's Association of America which met at the Hotel Windsor, Montreal, P. Q., on September 14, 15, and 16, 1920. The attendance was probably the largest at any convention of the association; the two hundred railroad men who registered represented railroads and private care lines in all sections of the United States, Canada and Cuba.

The first session was opened on Tuesday morning by President J. J. Gainey, who called upon Captain A. Layman of the Salvation Army for the opening prayer. Alderman J. P. Dixon, representing the city of Montreal, then welcomed the convention. T. J. O'Donnell, replying to Alderman Dixon, expressed the thanks of the members for the cordial reception and the pleasure of meeting in the

TRANSFERS AND ADJUSTMENTS OF LADING FOR MECHANICAL DEFECTS

BY J. M. GETZEN
Ass't Chief Interchange Inspector, Buffalo, N. Y.

"Money expended for productive labor is an asset, but when used to correct omissions and errors is a debit against the railroad paying it and the country as a whole." Under this standard, I wish to open up the discussion on transferring bad order cars and adjusting loads.

Acknowledging the necessity for transferring cars, we have an even division between unavoidable failures and misjudgment of selection of equipment. Among the former we may class: 1. Failures of inherent defects. 2. Failures through accident. 3. Failures through switching. In this category we must allow for natural causes: parts of cars will break, accidents will happen and our friends, the switch-

Dominion of Canada, for which the people of the United States have such a kindly feeling. He also touched on the importance of the work of the association in caring for 2,500,000 freight cars and 60,000 passenger cars and creating uniform ideas in regard to interchange on all American railroads.

Address of President Gainey

Following Mr. O'Donnell's response, President Gainey spoke as follows: Mr. O'Donnell has expressed my wishes all the way through and has left very little for me to say. I am glad to see as many ladies and gentlemen present as we have here this morning. I really did not expect so many to come on account of the long distance to be traveled. You all know the object of our meeting. It is printed on our invitations, and the most important part of that is "National harmony and unity of action, everywhere by everyone." If all the members of the association live strictly up to that, it will make our work each day less laborious and more pleasant.

The report of the secretary-treasurer was read and sent to the Auditing Committee, after which the reading and discussion of the paper on Transfers and Adjustments of Lading for Mechanical Defects was taken up.

men, will break up their quota of cars no matter how well regulated the organization may be.

In the latter class are: 1. Cars loaded in defective condition. 2. Cars unfit for bulk or high loading. 3. Cars too large for road clearances. We might go on indefinitely with reasons but from my observations most failures are comprised in these three and involve the carman mostly.

The judicious selection of equipment for the load it is fit to carry, is today the most vital means to reduce transfer, repairs and kindred troubles of the carman. The shortage of freight cars in practically every line of trade and its ever increasing demand seem to incline toward skimping on the general repairs and for this reason we must take the car as it stands, and here it lies in our power to classify it properly and prolong its life and usefulness.

To illustrate this clearly—there is not a time when we go over the cars but we find some of them plenty good enough for coarse freight, loaded with grain, leaking through ends and sides, the door post held in with a brake lever bolted through the sill, and adjoining it a first-class box car carrying barrels of oil or tar that had sprung a leak and ruined it for future high-class loading.

Another example is a twisted and contorted 50 ft. furniture car loaded 4/5 full of lumber. It was never designed

Chief Interchange Car Inspectors and Car

for this purpose and will not carry such a load safely. Generally speaking such are our transfers for body defects and hand in hand with it, cars loaded in defective condition. I do not think it necessary to enumerate the specific defects on truck or body that embrace such cars as we hew close to the rules. I might say, go a little better in repair rather than take advantage of the rules. May I not inject a compliment here to our private car owners, especially the packers? Never in my experience have we operated better equipment carrying the highest class freight we know of than we are at this time and they deserve the compliment unstinted.

Next we shall consider the adjustment of loads, and may I not pronounce this the most aggravating byproduct of carelessness? The greatest number of failures occurs unquestionably on house cars—"bad load at side door and door out"—due to no doorway protection in violation of Rules 1700 to 2908 of the Loading Rules covering the loading of various commodities in house cars. Why this should continue year in and year out is a mystery only partly solved and I am leaving this as a question to see if your experiences correspond with ours in trying to overcome the difficulty.

Open loads have the greatest inclination toward distress and too much care cannot be exercised in properly staking, wiring or blocking such loads. Most prominent are stone, pipe, spars, lumber, machinery, etc. Long hauls, and terminal switching dislodge such loads with even the best of blocking and if our shippers could be educated along the lines to secure their loads for sway and motion, much of our trouble and their own complaints would be overcome.

Automobile shippers, working with a committee of the A. R. A. have solved their troubles by religiously following their recommendations and their bad loads are practically zero. Why cannot the other shippers follow their example? Perhaps they have not yet realized that a little initial expense expedites their freight, keeps the car out of the repair track, and reaches the customer quicker and he is more satisfied than if delayed and damaged en route.

Transfers and adjustments converted to dollars and cents mean in our association that we pay between ourselves approximately \$25,000 each month to correct these omissions and errors, and while this figure appears large, the number of transfers and adjustments is nominal for a large terminal, the percentage being 23 cars transferred out of every 10,000 handled and 6 adjustments out of every 1,000 cars handled. We are keeping this percentage low only through most extraordinary efforts of our car foremen repairing everything within their power under load.

In conclusion, I want to add the appeal of our operating departments in their efforts to bring the car mileage up to

30 miles per day and lend our efforts toward this end by correcting as far as possible such errors by education and observance of the rules as they are given us.

Discussion

F. W. Trapnell, (Kansas City, Mo.): Mr. Getzen stated that a majority of the foremen were bending every effort to repair everything possible under load, in place of demanding a transfer. We are working along the same line. Everything that can be repaired under load is repaired, thereby obviating transfer and delay of the load incident thereto, with the claims that will accrue from the transfer by the change in the number on the bill of lading; whether there is any change to the contents or not, it will come and the railroad company will have to pay it.

E. R. Campbell, (Minn. Transfer Ry. Co.): In Minneapolis we transfer between 400 and 500 cars a month and in the Twin Cities probably 150 or 200 more. Most of our transfers are due to defective draft rigging and sills on open cars. At the Minneapolis transfer we have the large dray cars and we transfer and adjust loads. We aim to repair everything we can under load, especially commodities like automobiles and pianos, or anything of that kind. We have spent as high as \$40 and \$50 to repair a car and avoid a claim, because if we transfer a car of automobiles there is always a claim. We have spliced sills and put in new sills and draft rigging in that class of cars.

On the adjustment of loads, especially merchandise, nobody seems to pay any attention to door protection. We get all kinds of cars out of Chicago and I never saw a car loaded with merchandise that had any door protection. A car will come from us and go to Chicago and then there is a claim for door protection. In the milling district, all cars loaded with flour or feed are well provided with door protection and taken care of, but notwithstanding that, when they get down east, sometimes there is a claim for no door protection.

J. E. Vittum, (Columbus, O.): Most of the roads at Columbus, Ohio, repair their cars. I think that since we have the run repair or transfer system, the roads have been educated to make repairs on a larger measure than before, and those who have shop equipment, are making repairs to most of the cars offered in interchange, where the load has to be either adjusted or transferred. However, some of the points in our interchange are limited in their equipment and are unable to make the repairs as easily. I believe in the past two years, half of the cars that were formerly transferred because of defects are now repaired, and we have few transfers on loads at the Columbus interchange.

T. J. O'Donnell, (Buffalo, N. Y.): The paper that Mr.

Foremen's Association of America at Montreal

Getzen presents, is from everyday life. If we can eliminate any part of the \$23,000 or \$25,000 a month and put it in the treasury of the different railroads, we are doing our duty. You would be surprised to see the number of bad loads that we force the yard department to switch into the repair tracks every morning. There are at least three or four hundred and with the shortage of labor and transfer help, we switch them in with the feeling that they ought to load right at the initial point. If you are going to start a house car with two tiers of oil or vinegar, put in three or four coopeage boards to protect the doorway, because the center of the load will be up against that door and you will have to do it. Three dollars at the point of loading will be better than \$5 or \$20, or a wreck and loss of a life on the way.

We have been hammering at this for 20 years. The shipper ought to be made to put it in, or the railroad ought to be told for its own benefit; we will allow you the money that costs. The Interstate Commerce Commission told us that it is the duty of the shipper to protect his load. We ought to get this before the proper officials so it will have the desired effect.

I am wondering if it is a better investment to repair cars under load where you have a standing force and transfer platform, than to transfer them. You cannot repair a car under load as well as you can one that is empty. Are we patching up a lot of these sills to get the load through at the expense of the car? It is an open question whether you should transfer a car and repair the empty right when it is convenient to do so.

A. J. Mitchener, (M. C.): When I came to this division in May, we were transferring from 50 to 80 cars a day at a small point, Victoria. The average for the last three months is down now to 48. The repairs that we make to cars embrace the splicing of the center sill, draft timber and end sill, etc. We do not agree on some of the repairs, but as I look at it, it is easy for the repair track foreman to walk down a string of cars and mark transfer on them, but if you put a car on the transfer track, it sometimes takes a week; while you can repair the car under load in 10 hours. The foreman at Windsor couldn't agree with me on repairing cars under load, so I took 22 cars to St. Thomas, and agreed that if I repaired all of those cars under load, he would repair all of those that came after, and he is living up to his word.

A. Berg, (N. Y. C.): We handle the business on the line that has been outlined by those who have spoken before. We avoid transfer as much as possible, though it is permitted at Erie under the same conditions as at other points. It is the desire to avoid claims, and it is neces-

sary to repair under load on account of the transportation department being unable to furnish men to transfer cars, but I do not believe it is a very good plan because we are not able to give the cars the attention that they should receive; especially is that true of the 60,000 lb. capacity cars. Another detrimental feature brought about by the new rules is, on account of the high rates that are paid, we studiously avoid making any more repairs than are absolutely necessary to keep within the expenditure. It is rather deplorable.

P. J. O'Dea, (Erie): During the past two years my activities have been directed almost exclusively to work in connection with valuation for governmental purposes. There seems to be a consensus of opinion that the number of transfers and adjustments are becoming less, and it would be interesting if we had some thing to base that on. Whether it would be worth the labor that it would entail is, of course, another question. In almost every field the number of transfers and adjustments in later years have been very much less than formerly, and that is due to the fact that the equipment, generally speaking, is better than it has ever been before, which is due largely to the activities of the interstate commerce inspectors.

Much stress has been laid on this question of getting cars home, and that is predicated, I think, on the assumption that if they get them home they will get everything that they should get to make them right. My own observation is that the cars usually receive at the hands of the other fellow just about as good quality of repairs and as extensive repairs as they receive on their own home road. Everybody will acknowledge that money spent for transferring and adjusting is not productive. It is a waste of money. The car is not made any better, conditions are not made any more favorable, and it affords the shipper an opportunity of setting up a claim that he might not otherwise make.

C. W. Maddox, (C. & O.): Several years ago we transferred and connecting lines transferred many against us, but we have noticed a decided improvement in the last two years. It has been our practice to educate our foremen and let them use their own judgment as to whether a car should be repaired under load or transferred. We can splice the sills, put in new draft timbers and end sills in dump cars, and make such repairs as can be done just as well with cars under load as empty. Cars in that condition, I think, should be repaired rather than transferred, especially of late years when labor is so scarce. But good judgment should be used. I think some will attempt to repair cars under load that cannot be given the necessary repairs to go to destination. It would be well for us all to watch the condition of cars very carefully when deciding to make repairs under load.

E. H. Mattingley, (B. & O.): I want to agree with the

remarks of Mr. Maddox in regard to making repairs under load. There are certain commodities loaded in box cars which oftentimes cause a car to be made bad order and the defects cannot be repaired under load as well as when the car is empty. For example, splicing of sills. Oftentimes where a sill has been spliced by the method employed while under load, you will find the holes for the bolts are made large enough to slip the sills, which in my mind only means that the car will carry the load to its destination and possibly result in elongated bolt holes, resulting in split sills, which is no remedy of the situation at all. If you can repair properly under load, do so; but if you cannot make a car safe and serviceable, transfer.

In my mind the solution of the whole matter is to get the load properly loaded at the initial point. To accomplish that result a good plan is to have some one familiar with the territory call upon the individual shippers. In some cases you will meet with the response that other roads will take the cars regardless of the loading. By having a chief joint inspector, representing all the roads, call on the shippers, we can get results. In the Youngstown district of the B. & O. with four or five roads, each road represented called at the various shippers pertaining to steel shipments and obtained fine results. By concentrating your efforts in that regard, I feel that you can better the situation.

W. F. Westall, (N. Y. C.): I believe if we follow the practice of the B. & O. and let shippers know that cars are being sent out of their plants which do not comply with the rules, it would be well. We often find that the shippers do not know that the cars are being delayed because of transfer or readjustment, on account of not having proper door protection. If that is taken up at originating points, I think it would better conditions. In regard to loaded freight cars and cars equipped for conveying oil, the only way that can be improved is to get the cooperation of the operating department as soon as the cars are parked.

M. W. Halbert, (St. Louis): We transfer 3,000 or 4,000 cars a month in the St. Louis district. I find a great many of them are transferred on account of not having proper facilities to make repairs. Every car should be repaired under load that can be put in proper condition. I also find that when the mechanical department has charge, there are a great many cars repaired and run that are going to be transferred when the transportation department has charge of it.

T. J. O'Donnell: Do you want to stand here and say that we are bluffing, we are crucifying our own jobs?

M. W. Halbert: When the car foreman has charge of the transfer of bad order cars in our district, he is responsible for the transfer. He gets busy and looks into the bad order situation; if he can repair a car he will do it. If it is set over on the transfer track and the transportation department has a gang of men transferring, he will transfer everything.

T. J. O'Donnell: Who is responsible for the transfers?

M. W. Halbert: The car inspector.

T. J. O'Donnell: Then isn't it our duty to see that we repair every car we can rather than disturb the load?

M. W. Halbert: Certainly it is.

T. J. O'Donnell: Then why do we say to our superior officers that we would have less transfers if they gave the work to us? One of our superintendents met me the other day in the yard and said: "We have turned our work over to the car foreman. We were getting congested with transfers; we will have about a third as many. I want you to give me a record at the end of 30 days how it works out." He had four less transfers and 80 more bad loads.

M. W. Halbert: When you put it up to the car foreman he is going to get busy. The inspector will mark a car for transfer, and the car foreman would not have a chance to look at all the transfers; perhaps they are 8 or 10 miles

away, but in our district, when the car foreman gets busy on the transfers he is repairing cars and running them. He is railroading them through.

F. W. Trapnell: In our territory on some lines the car department takes care of the transfer, and on other lines the agent contracts for the transfer. We find that where the car department absolutely has the transferring of cars under its own jurisdiction, there are less transfers than when the superintendent or the agent has the transferring. Some of our connections are a long way apart. An inspector inspects a car and gets it for transfer; that car may be five miles from the car foreman. It is marked in on the transfer track and the agent starts in to transfer. When the transfer is placed with the mechanical department we will have less transfers than we have got today.

T. J. O'Donnell: A general car foreman should work on a mutual basis with the chief interchange car inspector. When a car inspector in a terminal yard condemns a car, he is not through with it. That car passes in to the repair track. It is up to the chief interchange inspector to see that that car isn't tampered with if it can be repaired under load. If you are going to leave the transfer of cars to the car inspectors you would be congested all the time.

F. W. Trapnell: In our report of the country there is a long distance between the repair track and the transfer track and the interchange tracks, and the man at the interchange tracks makes disposition of the car to the best of his ability, and it goes to the transfer track for transfer, and it isn't within ten miles of the foreman, or the general foreman. If he has to make a special trip that ten miles every day of course that is a different proposition. You have got a rather good supervisory force that we would consider could be done away with in our part of the country.

President Gainey: I agree with Mr. O'Donnell absolutely. I claim that the mechanical department is wholly responsible for every car that is transferred, whether it transfers it with its own force, or the transportation department transfers it. In Cincinnati our terminals are about 22 to 25 miles apart. In each large terminal we have a chief inspector. We have an inspector who goes through the entire yard the first thing every morning to see what cars the interchange inspector marked during the night. He examines these cars, and if in his opinion a car can be repaired, or is safe to run, he sends it to the repair track. Only cars that have to be transferred are sent to the transfer track. I cannot see why it cannot be done in every terminal in the United States. We transfer less cars coming from connecting lines than any road in the United States. We have gone as low as 15 cars a month, and we get the same cars going and coming that the other fellow gets.

In the last three or four months our transfers on all roads in Cincinnati have run higher than they should have run, and we have arranged for all the general car foremen of Cincinnati to get together and go through the entire terminal yards, and inspect the work of the inspectors, not saying anything to the inspectors of the time they are coming, and see whether the chief inspector who passed last on these cars is living up to what he is preaching. There have been more cars transferred against the C. & O. and the L. & N. and the Southern than on cars coming from the north. That is not due to the cars.

As Mr. Maddox has said, we repair 50 per cent of the cars under load. If a car is loaded with any commodity that you can splice the sills and nail the floor, you can do it just as well as you can empty and save the cost of the transfer. Every one of you knows that the transfer of cars is a waste of money, both for your company and the company that has delivered the car to you. I do not know of anything in railroading that will save more money for the railroad company than the stopping of transfers.

W. J. Stoll: At the large interchange points where a

chief interchange inspector is located, I do not see why any argument could arise when the general foreman and the chief inspector and his force cooperate. At our point we do not issue any transfer orders against any road unless we either see the car before or after it is transferred and by doing that, if one side transfers more cars than the other side, and we allow it, we are the fellows who are to blame.

A Member: I would say that the transfer of cars is on the increase. The paper that was read brought out the conditions about as we have it, while we have no statistics to back it up. I do not think anybody would be guilty of allowing a transfer if it could be repaired under load.

W. P. Elliott (Ter. Ry. Assn. of St. Louis): The transfer of cars not only should be charged to the car department, but they should have the transferring of loads under their jurisdiction. I know positively that you can reduce transfers. I know that in the Buffalo district and in the Chicago district there are cars being transferred today that could be repaired. We find a lot of cars are being transferred for lack of facilities to make the repairs and a lot are being transferred because the car foremen are sending cars to the transfer track on account of bad order condition. The result was to place the transfer of cars in the hands of the car foremen who were confronted with the problem of getting these cars transferred, as well as getting cars for the transfer, and we find it offsets his desire to shift the responsibility. If the matter is followed up closely by the car foreman, or the general foreman, as the case may be, it will eliminate a lot of transfers. Don't forget that the human element enters into it. There isn't a man here who won't sweep his own dirt before he will his neighbor's.

A. J. Mitchener: On June 10 we had 49 cars. I know we moved the cars. There were 49 cars waiting for transfer. In four days we repaired 46 of them. I am keeping a record of cars transferred against us by connections and I would be ashamed to hand a car back to a man for transfer for the small defects that they transfer against us.

W. P. Elliott: I want to substantiate everything Mr. Halbert said and I want to express my thanks to Mr. Getzen for the paper.

Secretary Keene: I move you that we close the discussion and tender a vote of thanks to Mr. Getzen for the valuable paper.

The motion was seconded and carried.

Tuesday Afternoon Session

At the Tuesday afternoon session the secretary read communications from F. H. Hanson, F. W. Brazier, F. C. Schultz and A. Armstrong.

F. W. Trapnell: I move you that our secretary be instructed to acknowledge these letters and telegrams by telegraph.

T. J. O'Donnell: While we are checking up our old friends let us not forget Henry Boutet and Stephen Skidmore. Let us send them a telegram, for they were really the bulwark of this association. (The motion was unanimously carried.)

The convention then proceeded to discuss the changes in the A. R. A. rules.

Changes in Rules of Interchange

Rule 2, paragraph 3. Loaded cars offered in interchange must be accepted with the following exceptions:

Section (c). Cars improperly loaded (not complying with the loading rules) when transfer or rearrangement of lading is necessary.

Cars loaded in excess of the maximum of Column A table under Rule 86, which is the total weight of car and lading on rails for receptive dimensions of axles shown.

A Member: Our practice at the present time where cars are transferred going home, is that they are sent home by the receiving company, so that a car can move home without any heavy repairs, if the car will go back.

T. J. O'Donnell: If we transfer a Burlington car against the N. Y. C. have we a right to return that car to Chicago?

W. J. Stoll: If the car is safe to go, yes.

T. J. O'Donnell: We had a car in our district that was home 80 miles from where we transferred it. It happened to be on a road doing business for two lines jointly. They said they would not take that car home; that we should get the receiving line to bill it home. I appealed to the officers that it was a reciprocal arrangement, that we could return empty cars from 1 to 300 miles providing the road connected direct with the owning road.

W. J. Stoll: That can only be handled locally by the officials of the different roads. It is a good arrangement.

M. W. Halbert: If the car is to be transferred and it does not belong in the St. Louis district we hold the delivering line responsible. If the car belongs in that terminal, it doesn't make any difference what the condition is, we send it to the home line, but otherwise a foreign empty car after transfer is returned to the originating line.

T. J. O'Donnell: Suppose the car belonged home 100 miles away, in defense of the road that transferred it, wouldn't they deliver it?

M. W. Halbert: They would not. It would be fair if we could get the roads to handle it that way. Under our arrangement, the trunk line handling the car will have to pay five cents a mile also per diem to get the car home. The line that did not originate it, isn't going to haul it home for nothing. The originating line will have to make disposition of that car.

T. J. O'Donnell: Wouldn't you recommend that that be done?

M. W. Halbert: Some of the roads will take it but if a car is out of commission why should any direct line haul it home for nothing? They never get a load haul out of it. But if we can make arrangements with the owners or the handling line and bill the car and get five cents a mile, we can handle it.

A. Herbster: In Chicago a car, even though not belonging to a Chicago road, and held by a road not connected direct, can be delivered to a road that has direct connection in order to get the car home. That has worked out very nicely. The Chicago district has been relieved of a great many bad orders, and I think the thing to do, even though it isn't as the rule reads, is to recommend that it be done universally.

T. S. Cheadle (R. F. & P.): Suppose road A delivers to road B a car loaded with a commodity which can be handed on to road C. The car isn't fit for any other commodity. They didn't bad order the car but permitted it to move through to destination. Possibly two months after, the car comes back; should that car be received back by the delivering line? Suppose no record was made of the car at the time it was received, but inspection showed that the same condition does exist.

C. W. Maddox: If a car is delivered and has to be transferred, and it does not belong to the receiving line, it should be returned to the delivering line for transfer.

A. Herbster: At the large interchange points they are not handled that way. If this thing works out all right at the large points, it certainly ought to work at the smaller interchange points where they have a chief joint inspection bureau. I believe it is good policy to get a car home and get it fixed up rather than holding it a year or two.

M. W. Halbert: During the war we handled the bad order situation as we had a mind to, and in St. Louis we had no congestion because any car was home wherever it was. We could start a bad order over some line and get rid of it, but today it is different. If the transportation department would leave it to us, we could handle the proposition very nicely; we could give and take, but some roads say "We won't haul that car 500 miles unless you pay us five cents a mile, or repair the car." If you get a car in that condition and can put it in condition to be loaded for

any kind of freight, it is a serviceable car, according to the rules. If you can get a load for the car and make it fit to go over the other fellow's line, you can start it, but an empty car, you cannot pass along unless you pay the road for hauling it.

Valentine Blatz (Wheeling): I fail to find anything in the A. R. A. rules stating that the smaller interchange points are governed by the action of the large interchange points. If we interchange a car and it is transferred for certain defects, there is no other way except to return it.

F. W. Trapnell: I move you that it is the sense of this meeting that the proper interpretation of that rule is, where a car is received by a road in bad order necessitating transfer of the load, that the car when empty be returned to the delivering line. (Motion seconded.)

M. W. Halbert: I think there ought to be a little added to it: A car home in the terminals will be sent to the owner.

F. W. Trapnell: I did not mean it that way. The car service association does not intend it that way. If I have a New York Central car and am connected with the Erie, in lieu of turning it back to the Erie, I give it direct to the N. Y. C. to save switching.

The motion made by Mr. Trapnell was carried.

T. S. Cheadle: Suppose the car was received and was not marked bad order. We get stock cars with pig iron delivered to another road. It is defective for a stock car. No record was made of it. Do the rules require that a record be made of it? Suppose it is loaded with watermelons and unfit for anything else.

T. J. O'Donnell: Then the car is traveling on its right. The physical condition showed that the car was such that it would carry the load.

T. S. Cheadle: It was fit for the load going up but it would not be fit on another line.

A Member: The car might not be fit for grain, but you could utilize it for something else.

Mr. Elliott: The reverse might happen tomorrow. These things are reciprocal, as I see them.

President Gainey: If I delivered to you a car to which you took no exception and you had it two months and returned it to me in bad order I would tell you to take care of it.

A Member: Under Rule 2, the car must be accepted back if in the same condition. We had a car loaded with coal with the dump door boarded over, delivered back with the boards gone. They put the boards back on and delivered it back to us in the same condition.

J. M. Getzen: The gentleman bringing up this question has failed to protect himself, in accordance with paragraph J. He admits it was defective when he got it. It was a trap door missing and boarded over. If he had put on "Bad order. Return when empty," it would have come back without any trouble.

C. W. Wolfe (Southern): Reduce the two months to two days. Could you tell him to keep it?

President Gainey: Not for two days. I will agree with you.

C. W. Wolfe: You cannot give it back unless you put a card on there, or make a record.

President Gainey: But he says he has no record of any defect when the car was delivered. He takes it and keeps it for two months and then brings it back and gives it to the delivering line.

C. W. Wolfe: I followed that for a long time but I made up my mind I would make a notation of it.

T. S. Cheadle: I confined myself entirely to the second paragraph of Rule 2. I am trying to see what the application of the rule is where the movement of one class of lading is through your line over to another line, and the car is moving back. The condition is the same, and if loaded with the same commodity it would be all right. The car isn't

fit for anything but that class of loading. If you had to make a report of it you would write the initials and numbers of the entire train of 80 cars and would delay the shipment. It seems to me that this rule can be applied as written in the second paragraph when it is on its home route, and that it should be received regardless of whether any record was made of it.

W. A. Rogers (P. & L. E.): As I understand it, it is a question of a car received in interchange, without any records taken as to its defective condition; that car, if moving backwards in home routing, must be accepted if in the same physical condition as when forwarded under load, whether empty or loaded. If I accept a car under load without any objection, the car is mine. The only way you can get rid of that car is, having a direct connection with the owner, or the car being in the same physical condition that you took it under load. You cannot deliver that car back in defective condition simply because you failed to protect yourself, providing it isn't moving on home route. If you get a car under load, you can deliver that car back empty if in proper home route, providing the record shows that your first receipt of the car is also your home route record.

T. J. O'Donnell: Isn't it a fact that we must have 30 or 40 per cent empty mileage? We cannot get loads all the time. We get 50 cars of watermelons. They are loaded on light cars without doors. We cannot load them over the road that gave them to us. We deliver them and I never hear about it. The car service department is utilizing these cars to take steel and coal. We have got to get our empties back to the mines. We are taking cars every day and if a car is delivered within a reasonable time the inspector never raises a question. The empty goes back the same as the load came up. We have got to stand by the handling of the car.

W. A. Rogers: In the Pittsburgh territory we have one road that is congested with bad order cars. They have taken it upon themselves to procure home route record, starting that car on a 2, 4 or 8 months' record. I say that the receiving road accepting that car under load, hauled that car to its destination, and if they find that car at the end of its destination is not fit to carry another load, I don't care whether it is chip baskets or steel, it is up to them to take care of the car. That is A. R. A. rule No. 1 which states what repairs you are to make on the foreign car while on your road. Why return it?

W. J. Stoll: A few years ago you all remember the Master Car Builders put their foot down on running cars under defects. If a defect exists on a car that the delivering line is responsible for, put on a defect card. Rule 2 clearly says that when a car is received by a receiving road with damages and takes its load to its destination, the delivering line must receive the car back.

W. A. Rogers: If in the same physical condition.

G. Lynch (Cleveland, O.): I am puzzled to know what the talk is about. If it is a loaded car offered in bad order in Cleveland, if the owner of the car is in Cleveland we return it to the owner. If it is a foreign car, we return it to the delivering line. If it is a car of melons off any of the southern lines and it is in bad order, we return it to the delivering line when empty. There is no trouble about this thing and I don't know what all the talk is about. It is a case of living up to the rule, as I see it.

W. A. Rogers: We are not talking about a car in the immediate vicinity of interchange. We understand that you can turn a car over to the delivering line or owner, if you have direct connection. We are talking about a car that goes forward without any exceptions being taken, and at the end of perhaps 400 miles it is found with defects. The railroad says it will start it back on a home route record. Are you going to take it with a couple of center sills split? If it was fit to haul a load to its destination, it is fit to

haul a load back. I do not believe in hauling defective cars all over the country; I believe in repairing them.

G. Lynch: The question is not the application of the rule as it is being discussed. If a car moves through interchange O. K., as far as the receiving line's records show, and it returns in a defective condition, after traveling for a week or a month, the delivering line has no right to accept the car. At least they can refuse it. The original receiving line is obliged to take the car back.

M. W. Halbert: The A. R. A. rules are plain enough. I cannot concur in the resolution passed. The rules say you must accept the car under load under certain conditions. It says you must return the car back to the delivering line in its same general condition. Here is the car that Mr. Stoll had reference to with the side posts rotted, the line that delivered the car was duty bound to run the car. Why penalize them simply because they forwarded the car with a load in it? If you try to pin down the delivering line on the bad order equipment you won't get any where. If you take a bad order car under load, with owner's defects, I do not mean defects that originated after the car was received, and when you get one of those old boats that will carry a load to its destination, why penalize the handling line, when you bring it right back; give it to the delivering line and say "Take care of that car." We have a lot of old cars in the St. Louis territory that belong elsewhere and we are trying to get rid of them. We cannot get any railroad to move them unless we pay for the haul or repair. Some of them you cannot repair under A. R. A. prices and make a first class car out of them. The way I look at the resolution, it is going to tie us up. This gentleman says after you get your car it is yours to do what you want to with it, but you are penalizing the fellow who takes it under load with its defects, after he accommodates you by hauling the load to destination and getting rid of the load. Why penalize him because he did not have any record of the car?

W. A. Rogers: It is in the same physical condition.

T. S. Cheadle: I move you that it is the sense of this body that the condition of the car may be established by actual inspection at the time the car was offered back, to determine whether it is in the same condition as received.

F. A. Donahue: Who is the judge?

W. A. Rogers: The receiving road.

RULE 4

The committee recommends that the second paragraph of this rule be modified in accordance with the proposed form shown below:

PROPOSED FORM.—Rule 4, (second paragraph). Defect cards shall not be required for any damage so slight that no repairs are required, nor for raked or cornered sheathing, roof boards, fascia, or bent or cornered end sills, not necessitating the shopping of the car before reloading.

A Member: If you receive a car that is damaged and reload it, it is your damage.

T. J. O'Donnell: Suppose we get a Burlington car with 25 sheathing boards missing. The Burlington takes it and makes the delivering line card it; what are you going to do?

F. W. Trapnell: Come back to you.

T. J. O'Donnell: I don't want the delivering road penalized.

F. W. Trapnell: If the Burlington repairs it, the delivering line is responsible.

T. J. O'Donnell: How are we to know what they are going to do? We can simply pass it along if we see it is not cardable without any thought of the afterclap. The refrigerator cars have to be carded.

F. W. Trapnell: And when they get home they always find defects we couldn't see and we always take it up and get the proper protection.

T. J. O'Donnell: Cut out carding unless you feel that the repairs are necessary at the time you card it.

T. S. Cheadle (R. F. & P.): Are the H 1 and H the only convertible freight car valves?

President Gainey: Those are the only ones. Suppose a foreign car when delivered had an H triple in place of a K triple; what would you do with it?

G. Lynch: We wouldn't do anything; let it run.

F. W. Trapnell: Where a non-standard valve is applied to a car that carries a standard valve, should a defect card be issued on the interchange track at the time of the delivery of the car, or, in accordance with our former practice, should it be on the basis of the joint evidence of improper repairs penalizing the party that put the wrong valve on, and not the delivering line? I think that might be on the basis of joint evidence of improper repairs.

G. Lynch: It isn't a cardable defect in interchange. It is a matter for the repair track, the same as wrong repairs; a defect card should be issued and attached to the car at the time the party made the repairs. If the car is coming home to the owner, then I would furnish joint evidence. If it is a foreign car to the receiving line, I would not.

P. J. O'Dea: Isn't it the intention to protect the owners on this high-priced valve, the same as on steel wheels?

G. Lynch: Rule 4 covers wheels, hose, and brake beams. Some lay great stress on the fact that the car is stenciled. We find a similar question in regard to substitution of the 5 by 7 with a 5 by 5 coupler. No one would issue a defect card in interchange. It is the same with the question we are now discussing. It is a cardable defect at the time the repairs are made. On interchange it is not.

President Gainey: I think you are absolutely right. I do not think it is a cardable defect in interchange. If it is a car coming home, it is a joint evidence card you want. If it is a foreign car you do not pay any attention to it.

RULE 32

The committee recommends that Section (d) of Rule 32, be modified in accordance with the form shown below:

PROPOSED FORM.—Rule 32, section (d). Collision, or impact other than that occurring in regular switching, such as:

- (1) *Misplaced switches.*
- (2) *Wrong or misinterpreted signals or failure to observe signals.*
- (3) *Letting cars get away on incline.*
- (4) *No rider protection when necessary.*
- (5) *Coupling on with locomotive at speed exceeding limits of safety.*

The committee recommends that the last paragraph of Rule 32 be modified in accordance with the proposed form shown below:

PROPOSED FORM.—Rule 32 (last paragraph). Defect cards shall not be required for any damage so slight that no repairs are required, nor for raked or cornered sheathing, roofing, fascia, or bent or cornered end sills, not necessitating the shopping of the car before reloading, the receiving line to be the judge.

T. J. O'Donnell: In discussing this rule Mr. Goodnow said that the committee had given it much thought and this was the best rule they could give. I cannot see any reason why we should not accept this and let it work itself out for a year or so. If you get a car with the sills broken and end all gone, you do your duty when you ask the man on paper how the damage occurred. If he tells you that it occurred in ordinary train service, take this literally.

F. W. Trapnell: Mr. Goodnow, chairman of the Arbitration Committee, gave us to understand that this rule would require more clerical work on the large interchange lines; and you would have to get after the superintendent and trainmaster to give you this information, but we find that the switchman and engineer get into a little trouble and they cover it up. They break a car in two and the switchmen make the statement that it was done in ordinary handling, and the engineer corroborates it. In investigating some of the cases we went to a car foreman and he gave us his side of the story; the trainmaster had no record of damage to the car. It looked peculiar that so much damage would occur to a car in fair usage, so we went up to the engineer and told him what we knew about the case and asked him what he was doing. It developed the fact that the road handling the car was responsible instead of the owner of the car. We have got to get to the bottom of each case and find out that we are not placing repairs on the car owner that should be assumed by the handling line.

G. Lynch: Rule 32 is perhaps impossible of enforcement

on the repair track or interchange track. While I agree with Mr. O'Donnell that it makes it easier for him or me, or any other joint inspector, we could get no information by investigation. We have tried that and the only proof we get is that they don't know. It is a loss of time and impractical to investigate such cases. There are all steel, modern cars that are all shot to pieces. They have not been derailed; consequently the owner is responsible. I have in mind certain private line cars, some have 15-in. center channels with a top and bottom plate, all broken. There is no redress because there is no proof of the car being derailed. The rule, in my opinion, should be rewritten; we might even go back to a combination or limit the damage beyond which the owner would be responsible just so long as we have this go-as-you-please handling of cars that the war brought on with liberal rules, or no rules at all.

T. J. O'Donnell: I want to bring out to offset what Mr. Lynch said that out of 12 cases we had, 5 of them admitted that the delivering line damaged the cars through unfair usage. That is a fair percentage. I cannot help believing that they will be honest enough to admit it. We ought to try the rule out. I think the A. R. A. is going along in a liberal way. We have only had 12 cases in a year. Our officials are very plain. If they have a car in a wreck and send it home they say "We had this in a wreck. Give us a card."

W. J. Stoll: The fact that the handling line is not penalized may not reduce the bad order cars any. My understanding of Rule 32 is that there is supposed to be a more rigid investigation made as to how the damage occurred.

T. J. O'Donnell: You know when you wreck a car and when you don't. When you are in doubt, investigate the case. I do not think we will have any trouble with this rule.

A Member: I don't quite understand the rule. Is there any other damage that could occur in a collision or impact outside of those designated in Articles 1 to 5 inclusive? For instance, switching from both ends of the track or throwing a cut of cars down into another switch would be an impact or a collision, but it is not designated in the five items.

F. A. Donahue (C. & O.): Was not Rule 32 put in force for the express purpose of making the man who had a weak car strengthen it?

C. W. Maddox: The only thing we can do is to use good judgment. I think we can tell whether a car has been damaged in fair usage, and if we find a car looks suspicious we can ask the yard people what information they have. I do not see how we can make any improvement in it.

T. S. Cheadle: We discussed this rule for about three hours last year, and finally somebody said it would have to be left to the man on the job. I am very much of the opinion that we should do the same thing this year.

W. A. Rogers (P. & L. E.): I believe you will have to take a car and if there is any controversy about it the owner will have to take it up with the delivering line.

J. C. Burke (Mo. Pac.): If you get one of your own cars home, how are you going to decide that the damage is done in rough handling?

T. J. O'Donnell: Get it from the operating officials of the road that you delivered from.

J. C. Burke: The delivering line would say, "No rough handling on our line." I take it for granted it would be the same in all cases of this kind. If the evidence isn't there to show that the car has been roughly handled the chief interchange inspector won't be able to decide.

T. J. O'Donnell: He will decide there's no unfair damage and make you do the work.

cars with two steel longitudinal sills only, the company on whose line such damage occurred must furnish owner statement showing the circumstances under which the damage occurred, if it is claimed that the damage was the result of ordinary handling. This statement, in the case of cars reported under Rule 120, to accompany request for disposition of car, and in cases where it is not necessary to report car under Rule 120 to accompany the bill for repairs.

The committee recommends that, in view of the foregoing note, the first interpretation of Rule 43 shown at the top of page 54 of the 1919 Rules of Interchange, be eliminated.

G. Lynch: Rule 43 is a twin brother of Rule 32. If the Arbitration Committee had stopped at the word, "Only," the rule would be a good rule, but unfortunately they continued on, and spoke of ordinary handling. I take the stand that a steel underframe car of present day construction cannot be damaged to the extent of buckling the sills or breaking them in ordinary handling. I do not know what the definition of the term "Ordinary handling" is, as referred to in this rule. That is something we should get defined. As it is, we do not know what ordinary handling is, and we do not want to report half the damages and hold up the car for an indefinite period. I would recommend, at the proper time, that Rule 43 conclude at the word "Only."

President Gainey: Do you say steel sills cannot be bent under fair usage? You see many a car buckled under fair usage.

G. Lynch: It is the definition of the term that is perplexing. What do they mean by "Ordinary usage"? Or "Fair usage"? My interpretation of both of these sentences would be: Judging from the condition of the car, I would say it was something more than the ordinary that did that damage. That is the only way that I could get a definition of the term. I cannot refuse to accept my own car for repairs, regardless of its condition, but this rule would give me a line on just where the responsibility would be placed. As it is now, we do not know where it is.

W. J. Stoll: In my opinion the rule is all right. If you break five sills you make your report accordingly, and if you break three sills, you make another report. The man who damages the car is to furnish a statement.

W. P. Elliott: When four or five sills are broken and nobody knows it, what is to be done when the car gets to interchange?

W. J. Stoll: The fellow that handles it is supposed to give a statement.

W. P. Elliott: They don't know. These cars are damaged in the middle of the yard.

W. J. Stoll: Cars don't derail automatically.

W. P. Elliott: The damage happens, and the car comes in interchange; I have the car, and am going to repair it. How am I going to give a statement that I don't know is true?

T. J. O'Donnell: You had better call a conference with all of the officials in your district and put that up to them, and tell them that beginning September 1 this rule will be in effect. You must have these statements and closer supervision when damage is done. Appeal to those that you are working with. Show the switchmen the amount of money that it means to your railroad, and that is all that you can do.

J. M. Getzen (Buffalo, N. Y.): I think Mr. Elliott is working under adverse conditions, for the reason that he is obliged to take a foreign car in interchange. If in his own mind he is satisfied that the damage happened in ordinary service he can repair the car. If there is a doubt in his mind he has a right to demand protection from the delivering line.

T. S. Cheadle: The chief joint inspector represents the line that delivered the car, as well as the line that received it. He could, in my opinion, handle that by knowing the exact condition of the car, but where there is no chief joint inspector it seems to me that Mr. Herring is right. The joint man should be in a position to get a statement from the delivering line as to how that damage occurred, before he could put it on to that line.

RULE 43

The committee recommends that the following note be added to rule 43:
NOTE—In the case of damage to more than five longitudinal sills on wooden underframe cars, more than four longitudinal sills on composite wooden and steel underframe cars, more than three steel longitudinal sills on steel or steel underframe cars and both steel center members on tank

W. P. Elliott: We are taking a great many cars from other lines; he would have some job.

T. S. Cheadle: He has to handle them with a clerical force. We are not honest with the other fellow if we don't, because if the chief joint inspector passes them out to a place where they have no chief joint inspector he has got to pass it.

W. A. Rogers: Is it the consensus of opinion that a car with such defects as outlined in Rule 43, if offered to the owner, would be accepted as owner's defect, and so passed upon by the chief joint inspector?

A Member: Yes.

W. A. Rogers: If there are no reports coming to the owner he will have to get it. An owner would get the car home with six sills broken; the chief joint inspector is the boss and the owner must accept it. If he would investigate and find that the delivering line damaged the car in switching, without a written statement of some kind, then what?

W. J. Stoll: The only thing we can do is to ask the delivering company or the handling line if they had any wreck or derailment.

T. J. O'Donnell: We have 7 out of the 15 that we demanded.

President Gainey: I agree with Mr. Herring. For example; the Southern delivered a Big Four car home with five or more broken sills, and he cannot specify how the sills were broken, who is responsible?

T. J. O'Donnell: Have you refused to accept it as owner's defect?

President Gainey: It is a penalty put on the delivering line for not saying how that car was damaged. If he can show that that car had six sills broken by dropping it over the hump or shifting a cut of cars, he furnishes the desired information, but in the absence of furnishing any information he takes the responsibility.

W. A. Rogers: You're getting in deep water. There is no evidence of that car being in a derailment. There are six sills broken and that is an owner's defect.

President Gainey: If the B. & O. cannot furnish evidence how these sills were broken it is responsible for the six sills.

A Member: What are you going to do with the car?

Answer: We ask the B. & O. how it happened, and for a card for six broken sills.

W. A. Rogers: Is the chief joint inspector going to issue the defect card on the spot, or wait two months?

President Gainey: He will give you a chance the same as on a joint evidence.

A Member: Suppose the car was damaged between the terminal and the place where the chief joint inspector is located and nobody along the delivering line knows that the defect existed until the chief interchange inspector finds it at the terminal, when it is delivered home and he says it is owner's responsibility; who is responsible if all of the sills are broken?

President Gainey: The delivering line is responsible if there are five or more sills broken if it cannot show how the car was broken.

W. A. Rogers: Are you going to issue defect card?

Answer: Yes.

M. W. Halbert: I think we should live up to the instructions of the Arbitration Committee. There is one thing I don't like and that is the investigation. I think under the volume of business we do in St. Louis it will be difficult.

President Gainey: Suppose a wooden car was delivered from one railroad to another in your territory, with five or more broken sills. If the car was going home, in the absence of the man delivering saying how this damage occurred, what would you do?

M. W. Halbert: I would make a personal investigation, and show my common sense, and if I thought the delivering line was responsible, I would say so. If the car owner, I

would say, "Take your medicine." You have got to make a decision. There are no two of us going to interpret the rules the same way. We have got to interpret them according to the defect on the car. That is the only way I see that we can get by. We might make a mistake once in a while, but I think the majority of times you will do right.

President Gainey: If a car was delivered home by a connecting line with five or more broken sills and the delivering line could not furnish the evidence, who will be responsible?

G. Lynch: The owner.

President Gainey: Why do you say that? The rule says that the road breaking those five or more sills must furnish you the evidence.

G. Lynch: I would ship the car to the home line and if the delivering line that damaged the car failed to make a report to the owner, the owner would pay. I have no report to make of the car to the owner or to the delivering line.

President Gainey: You passed the car, who's going to be responsible?

G. Lynch: The car owner; there's no evidence of derailment or side-swiping. I don't see any other way out of it.

J. C. Burke: If the owner has received his car home, and the inspector called to make an inspection and there are six sills broken and he knows that it is damaged from one of the five causes, under Rule 32 would he issue a defect card?

G. Lynch: Yes, if I knew that that car was damaged by any of the five items, even if it had a broken coupler, if I knew personally how the damage occurred, no investigation is necessary.

Thereupon the meeting was adjourned until Wednesday morning.

Wednesday Morning Session

President Gainey: Is there any further discussion under Rule 43?

T. S. Cheadle: I think it is a question whether a defect card can be issued under Rule 43. Can the line receiving the car demand a defect card under the rule as written for more than three sills without any indication or cornering or side swiping? At interchange points where there is no chief inspector, if a car comes home with five or more broken sills, would a defect card have to be issued?

T. J. O'Donnell: The receiving line naturally would look for protection, and I think time could elapse to find out how the damage occurred. I think the handling line would protect the owners in their own way, or arrange with the receiving line to take it home.

W. R. McMunn (N. Y. C.): The idea with some chief inspectors at interchange is that it will delay the car seriously in taking the matter up where we have questions as to how the cars were damaged, although in our district we have very little trouble. It is either a case of giving a card, or taking it up with the delivering line, to find out how the car was damaged. Out of 15 cases we gave cards for about 7; the rest were all owner's defects.

T. J. O'Donnell: I do not think that our higher officials want to be drastic against any equipment of that nature. The idea is this: The managements of these railroads in the last 10 years have spent millions to put their equipment in such condition that it will stand the severe handling that the motive power causes at this time. Is it fair for you to pay \$3,500 for a good 40 or 50-ton car and then permit somebody in another section of the country to pay \$1,200 for a wooden underframe car to go all over the United States and Canada and protect him on the service that that car is obliged to take with a heavy steel underframe car? If his car does not stand the ordinary service it is his duty as owner to bear any expense unless the car is derailed. It is a just rule and I think we ought to sustain it in its entirety. The big trunk lines of this country have spent millions of dollars to keep the equipment up to standard. If some see fit to maintain

a lower class of car, they should be perfectly willing to maintain it by the roads billing them for any expense to handle it. When the sills are broken in ordinary handling I think the owner ought to stand for it.

For that reason I move you that it is the sense of this body that Rule 43 be interpreted on the following basis: The handling line, in breaking the number of sills mentioned, if they see fit to repair the car before delivery, must furnish a statement to the owner when they render a bill for the items mentioned, as to how the damage occurred. If they deliver a car in interchange it is their duty to apply a defect card for unfair handling under the rules, and if not unfair handling, they must issue a statement to the receiving line, if it sees fit to repair the car and bill the owner.

G. Lynch: The motion reads that the defect card shall be issued at interchange and then the statement afterwards. That is contrary to the rule. The statement must come first and then the responsibility afterwards. The motion is wrong to that extent as I see it. It is a rule that is impossible of proper interpretation.

The question was put upon the motion and was carried, with but one dissenting vote.

RULE 108

PROPOSED FORM.—Rule 108. No labor to be charged for the inspection of cars, testing or adjusting brakes, adjusting angle cocks, tightening unions, nuts or lag screws or spreading cotters; sill steps, ladder treads or handholds, tightening or straightening on car; brake shafts or uncoupling levers straightened when not removed from car.
No charge to be made for the material or labor of lubrication, except as provided in Rule 66.

T. S. Cheadle: In regard to nuts tightened, in case draft bolts are loose and timbers down, and the bolts are tightened, are you entitled to charge?

President Gainey: If you make the card read "tightening draft bolt" you are. I would like to ask Mr. Stone on that question which is proper.

C. C. Stone (Southern): A charge against the owner would not be proper for tightening draft bolts. Rule 107 starts off and says "Labor charge shown unless otherwise specified." Rule 108 specifies no labor charge for tightening nuts. You cannot tighten a bolt unless you tighten the nuts.

T. S. Cheadle: It is undoubtedly a just charge to tighten up draft timber. It often requires considerable work and it is a protection to the owner's car. The rule does not provide for a labor charge for it.

President Gainey: No, but it says "Tightening bolts."

T. S. Cheadle: It appeals to me that it would be a legitimate charge.

President Gainey: It says "Tightening bolts 3/10 of an hour." You cannot tighten a bolt without tightening the nut, and if you tighten 8 or 10 draft bolts on a car, I claim you are entitled to a charge according to Supplement 3.

Mr. Barton (B. & O.): It all depends on the manner in which you make out the repair card. If you put on the repair card that you tightened the draft timbers, I think you will get away with it without argument.

Restenciling G. E. T. Cars

W. M. Herring (Southern): I want to ask with reference to restenciling G. E. T. cars as to what charge has been made. Of course the instructions specify that the charge will be in accordance with the A. R. A. rule, but I wondered if anybody had kept account of the actual cost. I had the matter up with Mr. McManamy to see if we couldn't increase the present amount on account of it being inadequate.

Mr. Barton: We kept account but after taking it up we found they were going to stand strictly to the rule.

W. M. Herring: Mr. McManamy said if we could justify it, he was willing to make it right; that he had heard of several roads making the same request. There was only three or four out of a hundred that asked for an increase in price.

President Gainey: Are you all charging in accordance

with the rules and have any of you taken it up with the government to increase that charge?

W. M. Herring: It costs us around \$3.50 and I asked if it could be put on the basis of time for reweighing.

President Gainey: Where you get the car out in the yard, you have to send the painter out there or put the car in and you cannot do it for the price, unless you take it for reweighing and restenciling, and then you can get pretty close to it.

W. M. Herring: Mr. McManamy said they had to comply with A. R. A. rules and he couldn't see why we couldn't restencil a car within the limits allowed on Rule 160. I told him that the nature of the work was different from stenciling a car to preserve its identity. I promised to give him something more definite as a reason. Of course it is a bill against the owner of the car, and they in turn bill the administration.

Maintaining Equipment Standards on Cars

T. J. O'Donnell: I would like to ask if the members are having any trouble on carding for a non-steel wheel under a car stenciled "Steel wheels." We are issuing a large number of cards and we feel that it is an injustice. The cars go through different interchange points and we are careful on the Canadian lines. We have to watch cars closely to comply with the instructions of the Canadian line officials. We receive any number of cars with no card on them. We always take the reading of the cast wheels so we will have the data. We are daily carding cars for steel and steel tired wheels. We find that the defect cards apparently have been removed that have been on the car. We also find when we card these cars against the delivering line that the mechanical department has traced and found that the car was carded prior to coming to our territory. The cards are removed by some one. We have sometimes blamed our inspectors, thinking perhaps they do not know what they mean; they would sooner tear it off than take the reading of it.

G. Lynch: Our experience in regard to that matter is that the repairing line refuses to put the card on the car at the time the repairs are made. We seldom see a card on a car at the time of interchange, and we are obliged to issue a defect card. That is in keeping with just what Rule 112 will be. No man will put a defect card on for damage. He isn't putting on a card for wrong repairs that he knows positively he made. The time to put a defect card on is when the repairs are made, not when offered in interchange. We have returned to several of the roads defect cards that were issued in error. Sometimes there is no stencil on a car; originally the car may have been stenciled "Wrought steel wheels" but the owner fails to maintain the stencils. We will have cars offered in interchange with other wrong repairs such as triple valves and no defect card is applied. This is also where the motion in regard to Rule 43 failed. I would ask a man when he makes wrong repairs to put a defect card on the car; that is the cure for the wrong repairs.

President Gainey: The rules bear Mr. O'Donnell out in what he is doing. They say it is a cardable defect in interchange. If a car is stenciled "Steel wheels" and it has a cast wheel, it is his duty to issue a card.

W. J. Stoll: Under government control defect cards were not issued, and there were a good many cars equipped with cast wheels that are now coming to the front and we have to card them.

J. E. Vittum: We have a great deal of trouble because of cars which were stenciled and equipped with steel wheels, but due to rust and corrosion the stencil has been eliminated, and we cannot tell by the reading of the stencil whether steel wheels are standard. Some of the roads are refusing, without the stencil, to issue a defect card because the rule specifically says if the car is so stenciled. I would like to know what the roads are doing, whether they generally are refusing to issue defect cards, although well aware that steel wheels are standard to that equipment.

President Gainey: I think the rule is a good one the way it stands. If a railroad spends the money to put steel wheels under a car instead of cast wheels, it should be protected. We have inspectors on all interchange points, and of late years they have had very little carding to do, and that rule should be lived up to strictly. There is no good reason why an inspector should fail to see a cast wheel in place of steel.

A. Berg: Often cars are away so long that they lose their identity. The stencil and everything else is gone. The owner has no opportunity to maintain it. In view of the fact that this condition exists and we have been penalizing on account of the failure of the party that damaged the wheel to comply with the rules, it behooves the interchange inspector to afford protection.

J. M. Getzen: I want to go back to Rule 88. In our district we are receiving home a large number of cars bearing defect cards reading: "One pair of wood draft timbers in place of metal draft arms, labor only." It isn't my understanding that that rule is intended to deprive the owner of charging for labor and material on such repairs when he gets the car back. I would consider such repairs as temporary. The defect card is wrong, in having that item "Labor only."

F. W. Trapnell: If he considered that as temporary repairs and secured a defect card for labor only, he got more than he was entitled to, because it is my opinion that all he would be entitled to there would be the scrap value of the material that was lost. There is a case in the arbitration decisions between the St. Louis-San Francisco and C. B. & Q. When I offered to make settlement for temporary repairs to give them the scrap value of the material that was removed from the car and settle the case, they thought I was wrong. We took it to the Arbitration Committee and they said if it was temporary repairs, all that the Frisco would be entitled to would be the scrap value of the material, and that was draft arms and metal draft bolster.

J. M. Getzen: What I wanted to bring out was, when you place a defect card on a car it is natural to assume that you bill for those repairs. If you have done that you must be billed for the wood parts and expect to get paid only the labor of substituting.

T. J. O'Donnell: Suppose you bill out wooden draft timbers at a point where you have no metal in stock. My idea is that you should charge for your wood and labor. When the owner comes back he should simply charge for his metal draft arms and the changes. We have a right to put in the wood in place of metal, where we haven't the proper material.

A Member: In that case the defect card should read for material.

J. M. Getzen: It is wrong repairs if you are going to bill it. If we are taking away 500 or 600 lb. of steel, it is wrong repairs.

A Member: This rule protects you when these parts are missing and you issue a defect card for the material, but I do not think there is any defect card due you for labor.

President Gainey: Draft arms that extend 30 in. beyond the body bolster cost \$150 or \$200 a car. We put in wooden draft timbers and send the car home. The owner is undoubtedly entitled to pay for the draft arms that have cost him \$100. I should think the proper way would be to card the car "one set of wooden draft timbers in place of steel."

W. M. Herring: We have had a number of cars come in with wooden timbers and as yet I have been unable to find out in any case by whom they were applied. I have received no bill. I have traced the movement of the cars, and the roads say they have no record of having made the repairs. We have also had cars destroyed on foreign lines,

and when we sent a statement showing the depreciated value of the car we showed metal draft arms in accordance with our record. The line having the car in its possession at the time of destruction showed that the car was equipped with wooden draft timbers and wanted us to change our statement. We have had the same thing on metal body bolsters. I could find no arbitration decision to cover that. The only way out I can see is to submit it to the Arbitration Committee for a ruling, as to whether a line destroying a car could settle in accordance with the standard, or according to the condition at the time it was destroyed. It does not seem right to penalize the line destroying the car by charging for a metal arm or body bolster when the car was not so equipped; still the owner should get some protection. On all the cars destroyed during federal control, we have received no protection. We have not found a defect card on any of the cars that came home with wrong repairs, either for material or labor, and when we have traced the car back, we have been unable to find out by whom the repairs were made.

W. M. Herring: I think he should be protected on material. Rule 95 will give him that authority.

P. F. Spangler (St. L.-S. F.): The rules set forth the specific items of material which you are required to carry in stock. If you do not have the material in stock and substitute wrong material instead, you are responsible to the owner for the labor and material. If, to expedite repairs, you substitute wooden parts, all you are liable for is the labor and you should attach your card to the car. I often throw away a body bolster and substitute wood, attaching a defect card for the labor only, allowing scrap credit for the bolster removed and bill for the labor and material of the wooden bolster applied. Rule 122 is plain on that.

T. S. Cheadle: Rule 16 says that the original construction of the car must be maintained. If you replace a wrong draft arm in place of the right one, you would only be entitled to the labor. These parts that we have to carry in stock are regular A. R. A. material. I understand it has been done, but it was not the intention to permit you to put wood in place of metal and only pay for the labor.

(At this point the discussion on the Rules of Interchange was closed. The papers presented at the later sessions will be published in the next issue.)

CARS BUILT THIS YEAR.—Statistics regarding the number of freight and passenger cars delivered to the railways of the United States by 23 car building companies during the first seven months of 1920, show that these amounted to 21,000 freight cars and 49 passenger cars. This indicates that 1920 is likely to furnish a new low record for car production. The number of cars on order and undelivered increased steadily since the first of the year, until at the end of July the orders amounted to 50,275 freight cars and 811 passenger cars, the increase being obviously due to the fact that the builders were receiving orders faster than they were turning cars out.

NEW YORK CENTRAL MOTION PICTURE, "BULLETIN 70".—Marcus A. Dow, general safety agent of the New York Central, has brought out a fourth motion picture for use in giving safety lessons to the employees of the road. Unlike "The House That Jack Built" and other films heretofore produced for the New York Central, the present one deals mainly with the startling facts of the railroad accident records of the whole country.

The title of this film is "Bulletin 70," and the story is based on the annual statistical accident report of the Interstate Commerce Commission for the calendar year 1918, which was contained in the bulletin of that number. That record tells of 9,286 persons killed and 174,575 injured on the railroads of the United States in the twelve months, and the details and classifications of casualties fill 30 large pages—not to mention \$40,000,000 in money damages. Mr. Dow has been able, of course, only to touch a few of the "high spots" of the record.

A NEW METHOD OF CASE HARDENING STEEL*

Former Methods Are Compared With a New Process
of Case Hardening by Regenerated Cyanogen Gas

BY WM. J. MERTEN

Metallurgical Engineer, Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa.

IRON and low carbon steels absorb carbon from so-called carburizers very readily when in contact with these carbonaceous materials at temperatures above the upper critical point. The quantity of carbon absorbed depends upon several factors. One of these is the temperature or degree of heat above the critical point of the steel. In other words, the higher the temperature, the faster and deeper the penetration of the carbon.

The character of the carburizer is also an important factor in the successful conductance of case hardening including the depth of the case. Elementary carbon as such is only of secondary importance. Oxygen and nitrogen compounds which are added or are naturally present in the so-called energizers are necessary to generate nascent gaseous carburizing mixtures of carbon monoxide and cyanogen gas (CO and CN).

The percentage of carbon present in the steel used for case hardening has also a marked influence upon the affinity of the material for more carbon up to saturation; more specifically, a low carbon steel absorbs faster than high carbon steels.

The presence of chromium, tungsten, or manganese accelerates the absorption of carbon since they form double carbides with the iron. Nickel and silicon, however, retard the absorption. The fact that they form solid solutions with iron may be the cause for this retardation.

From statements made in the second paragraph it is readily conceivable that, if a properly heated piece of steel be brought into contact with pure nascent gas continuously generated in a separate unit or chamber and preferably under pressure, the conditions for case penetration would approach the ideal. A process of this type is the one presented in this paper, preceded by a survey of the processes now in vogue with their disadvantages and deficiencies.

Present-Day Methods of Case Hardening

The most general and commonly used method of case hardening is conducted by packing steel parts in a metal box filled with carburizing materials and firing the tightly closed box and contents at a sufficiently high temperature for an adequate length of time to give the desired depth of case. This process is quite simple and assures fair success if properly conducted in accordance with a prescribed proce-

dure, experimentally determined to give certain definite results under definite and specific conditions.

The disadvantages of the above process are as follows: (1) uncertainty of proper reaction within closed box; (2) difficulty in duplication of results as predetermined, because of non-uniformity of carburizers; (3) long time exposure of the steel to a heat not well controllable, producing a questionable structural condition; (4) high cost of operation because of inefficiency of the heating method; (5) cost of boxes due to rapid deterioration of same by oxidation.

The second method to be mentioned is case hardening by immersing the steel article in a cyanide bath heated to about 860 deg. C. (1580 deg. F.). This process is convenient and effective on small articles only and where the depth of the required case is not more than .005 in. to .015 in., or where mere surface hardening is wanted. This is a fast case-forming method and from 10 to 15 minutes gives the desired depth. The outstanding disadvantage of this process is that no uniform case can be produced. The parts deep in the melted bath do not get the same depth of penetration as the parts near the surface. The evolution of the cyanide gases at or near the surface favors the penetration and it is hardly feasible to have pots with a large enough surface area to take care of the case hardening of a plant.

The third method consists of dipping a cherry red piece of steel or tool into a container of powdered cyanide salt, such as potassium cyanide, sodium cyanide, ferro and ferri cyanides, or sprinkling the powdered salt of these cyanides on the red hot steel surface and putting the steel back into the fire again. The case hardening produced in this way is very superficial. In the fourth method the carburizing gases are passed over a piece of steel heated in a retort. This process is applicable to parts that are intricate in design.

The process to be discussed next, although still in the experimental stage, owing to radical changes in the principle employed, appears to present opportunities for efficiency, preservation of the product, simplicity of operation, uniformity of results, speed of operation, reasonable cost, and wide range of utility. This process may be called a regenerated cyanogen gas case hardening.

Cyanogen Gas Case Hardening

It has long been recognized that the most efficient carburizing gas is cyanogen (CN). The case is of a greater

*Paper read September 9, 1920, before the Pittsburgh Chapter of the Steel Treating Research Society.

uniformity, is more rapidly produced and penetrates deeper than one produced by carbon monoxide (CO), but the highly poisonous character of the substance has been a serious objection to its use. The tendency is to wastefully lead the gas to the stack and out of harm's way, instead of controlling it to get maximum efficiency.

To case harden steel and iron alloy articles in a stream of cyanogen gas evolved from a container filled with an alkali cyanide salt, heated by electrical energy or other means to accomplish vaporization or boiling of the salt, is the principle upon which this process is based.

The articles or materials to be processed are independently heated out of contact with the fused cyanide salt. The advantage of this will readily be appreciated on recalling the statements made regarding the fact that case hardening is produced by contact with gaseous and not with solid carbon

liquid as required, thereby retaining the original supply of cyanide salt intact.

To prevent the poisonous gases from escaping into the room, the suction fan indicated is shut down before the charging door is opened and a bell ventilating device for inducing draft is arranged so as to open the bell when the fan stops and prior to opening the door.

Parts of the pump or suction fan should be of non-ferrous metals such as copper, basic alloys or hard copper. Water cooling jackets or other protective methods are to be employed for the return flues for hot gases and the nozzle end of the flue must be of hard copper, monel metal or other non-ferrous alloy with a high melting point.

Sodium cyanide melts at 600 deg. C. (1112 deg. F.) and boils at 800 deg. C. (1472 deg. F.). The temperature of the pot must therefore be not less than 800 deg. C. and to effectively absorb this gas the steel is at a temperature above the critical point or about 900 deg. C. (1650 deg. F.).

The furnace illustrated in sketch is a design for the processing of shafts, etc., but a slight modification of the upper or steel heating chamber will adapt it to a variety of work. Grates of nichrome metal with knife edge supports are used.

The advantages of this process are the following: (1) temperature control is more perfect since the pyrometer is inserted directly in the heating chamber; (2) a finer, more uniform, and deeper case can be secured than by any other processes and less time is required; (3) the use and storage of carburizers and carburizing boxes is eliminated.

It should be noted that while some of the less important features of this process are still speculative in character, because of the experimental stage of the development, the method is based upon well known principles and the conclusions have been drawn from a careful study of general case hardening practice.

CARBON AND HIGH SPEED STEEL*

BY J. J. RYAN
Baltimore & Ohio

The forging of tool steel has received less attention than annealing or hardening. Nearly every smith has had more or less experience, but those who forge tool steel as it should be done are scarce. Most smiths think all that is necessary is to forge the article to proper shape and size. They pay little attention to the heat so long as the steel does not fly to pieces.

Occasionally tools are forged at too low a temperature, which is nearly as bad as overheating. Tools forged at too low a temperature will be very brittle, and internal strains are produced which are very liable to crack or spring the tool in hardening. I have seen many smiths who overheat the steel and then hammer it long after all traces of red heat have disappeared. Hammering steel at black heat should not be done under any circumstances.

To properly forge tool steel, have a clean fire deep enough so that the blast will not strike the steel. Keep the steel slightly covered, heat slowly and evenly and turn it over frequently. For a large tool or forging, several heats are required, but it should be finished at a dark red. When the red disappears it is time to stop hammering. When finishing a tool, several heavy blows are necessary to make the steel compact and fine grained.

Good cold chisels, like good steel workers, are scarce. They are the most abused tools in the world. Cold chisels should be made of steel containing from 70 to 80 points carbon. First cut off enough steel to make it the desired length. Heat it to a bright red back about three inches; then trim off the corners on two parallel sides so that the end will have a short, blunt point. This will keep the edges

and more especially with cyanogen gas. The depth of penetration is then only a function of the uniformity of the temperature of the article treated and the duration of treatment. Nascent cyanogen gas has a speed of penetration of four or five times that of carbon monoxide.

The furnace shown in the sketch embodies the regenerative principle since the excess gases not absorbed by the steel are forced under pressure into the fused cyanide (CN) bath, are reheated, causing a vigorous stirring of the bath, and a lively evolution of cyanogen gas, leaving with more energy and larger quantities, therefore more vigorously attacking the steel surface, causing accelerated and deeper penetration.

This regenerative type of furnace is a means to use the rather expensive salt economically, as the nitrogen gas on returning will combine with the sodium and a carbon supply in some cheap form such as charcoal can be added to the

*From a paper read before the International Railroad Master Blacksmiths' Association.

from lapping over in forging. Draw the chisel on the horn of the anvil the first heat and it will not require as much hammering on the edges to get it into the proper shape. The less a chisel is hammered on the edge the better it will be. When it has been hammered on the sides until it is a dark red never turn it up edgewise and strike it. If it must be hammered on the edge put it back in the fire and heat it again, do all the hammering on the edge that is necessary and then hammer it evenly and thoroughly on the sides, but do not strike the edges again. When you get the chisel nearly to size and shape, medium heavy blows are necessary to pack the steel. This should be done when the steel is a very dark red, but when the red disappears, stop hammering immediately. Put the chisel in the fire but do not turn on any blast. As soon as it is a dark red take it out and give it several good blows on each side, then heat again and hammer as before. Repeat the operation three or four times but remember to keep your hammer off the edges. If the chisel gets too wide or the edges get crooked, it can be filed or ground to shape.

In making a flat chisel out of 3/4-in. steel, draw it out so that it will be about 1/8 in. thick at the end, and about 1/4 in. thick three inches from the end. A chisel of this size should be about 7/8 in. or 3/4 in. wide and a trifle thicker in the center than it is at the edges.

When the chisel is forged, let it cool off and grind it. When it is ready to harden, heat it to an even dark red back as far as it has been drawn. Plunge it in the bath straight down as far as it is hot enough to harden; move it up and down slightly but not sideways. As soon as the chisel is cooled through take it out and rub one side bright and then hold it over the fire, and drawing it evenly to a regular cold chisel blue.

A chisel made in this way can be worn back three inches before it needs dressing and the edge will stand far better than the ordinary chisel made like a blunt wedge and hardened about 1/4 in. on the end, as it is generally done.

Two Types of Tire Steel Wheel Lathe Tools with Inserted Cutting Blades

This method of forging steel holds good on all flat tools and tools that can be finished on the flat sides, such as side tools, flat drills, cut-off tools, etc.

BY R. W. MILLER
Baltimore & Ohio

We are compelled to be specific in stating what each round, square or octagon bar of tool steel is to be used for. We have about three grades of carbon tool steel that vary from 90 points to 150 points carbon and one high speed steel. This is standardizing as far as it is possible and when we have a furnace for heat treatment of tools equipped with a pyrometer to gage the heat, the tool question is reduced to a science. One man should be placed in entire charge.

None of our car wheel and locomotive lathe tools are of solid high speed steel shanks, as they are forged from tire steel and tipped with high speed steel by electric welding. I have experimented very extensively in welding high speed tips to tire steel and find that the best way is to electric weld them. In using solid high speed steel, after the largest tool becomes too short it is drawn down to the next size that will make the tool long enough without any waste, and so on down until the last operation will produce a piece 3/8 in. by 3/8 in., 2 1/2 in or 3 in. long, to be used in one of our own make tool holders. We save all the cuttings and trimmings, which are reclaimed at the Mt. Clare shops, Balti-

Method of Applying High Speed Steel Tips to Tire Lathe Tools by Electric Welding

more, Md. I know of no other process with less waste. In one year's accumulation we have about 25 lbs. of high speed steel scrap, which is sent to the Mt. Clare shops.

All our large taps and reamers are also made from scrap pieces of high speed steel. The bodies of these reamers are made of soft steel, case hardened, and the cutting blades inserted.

All high speed steel is annealed by placing the steel so that the pieces will not come in contact with each other, in a filling of two-thirds iron borings and about one-third charcoal. This is placed in an oil furnace, brought up to a good heat and left in the furnace to cool as the furnace cools down, about 10 or 12 hours, after which the box is taken out of the furnace and kept in a dry place for about five hours before opening. The box for holding this material is a 12-in. or 14-in. pipe about 18 in. or more in length with a plug in each end and a 3/8-in. rod passing through the box from end to end to hold the plugs in position. The plugs are tapered to draw up tight.

In hardening high speed steel parts a furnace is used for large pieces and a forge, bricked up to retain the heat is used for small pieces. The parts are quenched in linseed oil, moved up and down, not in a circle. The 3/8-in. by 7/8-in. by 12-in. blades warp a little but are forced into their seats in the reamer and are peened with a hammer to make a good fit. A collar at the top end of the reamer keeps the blades from being forced upward in using the reamer.

Our large tire lathes are equipped with tire steel holders of the type shown in the drawing, with inserted high speed steel cutting parts. We have taken cuts 1/4 in. wide and 7/16 in. thick with these tools.

Discussion

The suitability of open hearth carbon steel for tools was discussed by a number of the members who have had experience with it, the consensus of opinion being that this material is not suitable for tools and that crucible steel should be used.

The methods of forging tools described in Mr. Ryan's paper were generally conceded to be excellent, but a number of the members took exception to them as being too slow to satisfy the demand for output which must be met in railroad shops. A number of instances were mentioned where chisels are dressed under small belt driven hammers which make it possible for one man to dress several hundred chisels in an eight-hour day.

LOCOMOTIVE WHEEL BALANCING MACHINE

Device Used in British Railroad Shops Tests Wheels
by Rotating Them in Spring Supported Bearings

IN American railroad shops little attention is generally given to accurate balancing of locomotive driving wheels. Improper balance increases the stress on the rail and on the machinery and causes bad riding qualities. For that reason it seems that the matter should receive more attention. The greater refinement in this respect that is prac-

each bearing being supported on four springs so arranged that the bearings may "float" and vibrate with the axle, should the wheels when spun be out of strict balance. As will be gathered from the accompanying illustrations, the bearings and their springs are supported from cast iron frames split horizontally to permit the wheels to be inserted and bolted to the foundations in a manner permitting the distance between the frames to be adjusted to suit wheels with inside or outside bearings. The spring bearings of the ma-

Balancing Machine Showing Driving Motor and Flexible Shaft

ticed on British railroads is exemplified by a machine for balancing locomotive driving wheels designed by G. J. Churchward, of the Great Western Railway, and described in *The Engineer*. This machine was first installed at the Swindon shops of the Great Western and since that time has been put in use at Crewe on the London & North Western, and Doncaster on the Great Northern. In commenting on the use of the machine *The Engineer* states that while the theory underlying the balancing of locomotive wheels is well developed, a locomotive wheel that has been balanced purely by calculation is seldom if ever completely free from the

Details of the Floating Bearing

chines are also split horizontally, and can accommodate brasses of different internal diameter to suit axle journals of various sizes. The brasses are bedded not directly against the cast iron external straps of the spring bearings, but against spherically backed brasses with which these straps are

Arrangement of Motor, Flexible Shaft and Bearings

action of unbalanced centrifugal forces when running. The results secured with this machine have demonstrated that all locomotive wheels, however carefully the balancing calculations have been conducted, should be subsequently examined experimentally and adjusted in accordance with the condition shown.

The machine consists of a pair of bearings for the axle,

lined. Thus any faulty alinement of the bearing brasses or any tendency for them to get out of alinement by a possible whipping of the axle or similar movement can be accommodated.

The upper and lower halves of the cast iron straps carrying the bearings are tied by bolts to the upper and lower halves respectively of the surrounding cast iron frames.

These ties, however, are quite loose and are intended merely to limit the extent of the vibrating action without interfering with the early stages of its development. The weight of the wheels and the unbalanced centrifugal forces, if such forces exist, are transmitted to the surrounding frames entirely through the springs.

The wheels are driven by a 35-hp. electric motor, the driving connection being established through an extensible shaft, having a Hooke's joint at each end. The final portion of the Hooke's joint next the wheel is bolted to a plate, which in turn is bolted to the spokes of the wheel. The center line of the driving shaft must, of course, at the outset be accurately collinear with the center line of the axle in order to avoid introducing an extraneous source of vibration. To facilitate the attainment of this condition when the wheels are being set up in the machine, the final portion of the Hooke's joint next the wheel is provided with a spring plunger in the form of a lathe center, and the driving plate is bolted to the wheel spokes with this plunger entered into the center mark on the axle end. A tachometer driven off the motor shaft permits the speed, in miles per hour at which vibration begins, to be noted.

Brake equipment, comprising two brake blocks per wheel, is provided in order that the wheels may be quickly brought to rest at the end of a run. The brakes may be applied either by means of a hand wheel or by admitting air at 90-lb. pressure to a standard 8-in. cylinder.

Before a test is made the small portions of the axle journals projecting clear of the spring bearing brasses are smeared with red lead, and the point of a spring plunger marker—clearly shown in one of the illustrations—is brought within a short distance of each smeared surface. These markers when vibration begins, scrape away the red lead lying

Balance Weights Applied to Wheels with Outside Cranks

towards the radius of the wheel along which the unbalanced centrifugal force is developed.

It is the common practice in Great Britain to take the revolving masses plus two-thirds of the reciprocating masses, and to regard the sum as the total revolving mass to be balanced. For each type of wheel the calculated amount of the revolving and reciprocating masses to be balanced is represented by a weight or weights attached to the crank pins, the weights in the case of an inside cylinder engine being split and held to the crank pins by means of straps. To secure correct results it is important that the weights representing the portion of the reciprocating masses to be balanced should revolve in the plane in which these masses reciprocate. In the case of coupled wheels, therefore, temporary extension pieces are attached to the crank pins,

so that the weights representing the reciprocating masses may be brought out into the plane of the connecting rod, crosshead, piston, etc.

In balancing wheels they are speeded up until they begin to vibrate and are then brought to rest, and a trial weight is bolted to the spokes at a point indicated by the mark on the axle. They are then again brought up to speed, corrections in the counterweight being made until they are in complete balance up to and at the maximum speed. When the correct weight has been found a draftsman determines from its magnitude and position the additional weight which must be added to the wheel to secure proper balance.

To facilitate changes in counterbalances they are cast with pockets or formed from steel plates riveted on each side of the spoke with lead poured in between. The lead is alloyed with antimony, which causes it to expand on cooling and

Balancing Machine with Wheels for an Inside Cylinder Engine

avoids the trouble experienced due to the counterweight pounding to pieces when pure lead is used. It is interesting to note that when a pair of wheels for an inside cylinder engine was run in the machine distinct signs were noted that the crank axle was "breathing" under the action of the centrifugal forces on the balance weights in the wheels. As a result the practice had been adopted of building up such axles with balanced cranks and applying the balance weights entirely to the crank webs and not to the wheels.

APPRENTICESHIP IN FRANCE.—As a means of providing for the present shortage of skilled labor in France, a law has been promulgated providing for the creation of technical classes for youths under the age of eighteen employed in works and factories. Employers themselves have the right to establish classes for their hands, but where this is not done the classes must be instituted by the chambers of commerce or by professional groups with funds provided partly by the state. There is a general feeling that the state should not be permitted to monopolize the instruction, and employers are, therefore, urged to provide the instruction themselves as part of the technical training of their hands.

IMPROVEMENT IN SCREW MEASURING MACHINES.—Dr. P. E. Shaw, of University College, Nottingham, England, has improved a screw-measuring machine, which appears to be simple in construction and rapid in operation. All the movements are sliding, thus greatly reducing the time needed for measuring. One special merit claimed for the new machine is that it is equally applicable to plug and ring screws. There appears no reason to doubt that this claim is correct, in which case a distinct advance in metrology will have been secured. The accuracy of the new machine is stated to be to 1-5,000th of an inch on diameters, and 1-20,000th on pitches, both in the case of plug and ring screws.—*Scientific American*.

LABOR-SAVING DEVICES ON THE SANTA FE

Aggregate Savings Due to the Adoption of Apparently Simple Shop Kinks Often Are of Great Importance

BY J. ROBERT PHELPS

Apprentice Instructor, Atchison, Topeka & Santa Fe, San Bernardino, Cal.

EFFICIENT shop devices that have worked out well in actual practice in the San Bernadino Shops of the Atchison, Topeka & Santa Fe are shown in the accompanying illustrations and described below.

Clamps Used on Tire Boring Mill

In boring the largest tires for passenger locomotives, it was found a difficult task to clamp them to the boring mill

Fig. 1—Clamp for Holding Tires on Boring Mill Table

table owing to their large size. Before making the clamps, shown in Fig. 1, bolts and blocks were used, requiring considerable time for the set-up and not holding the tires firmly. To obviate this difficulty, special clamps were forged with T-heads to fit the slots in the boring mill table, the clamps

Fig. 2—Jigs for Machining Steam Pipe Joints

being offset to pass around the tire and having set screws for tightening the tire to the table. In setting up on these screws, all the pull comes directly on the tire which is held firmly to the table by six clamps, or as many as may be necessary.

Facing Steam Pipe Joints

At one time in railroad shop practice it was thought advisable to make up all steam and exhaust pipe joints using white lead. Under the action of high temperature steam over a considerable period of time, this white lead acted on the joints to make them very rough. The result was that they often required machining before being ground in and this work was formerly done at San Bernardino on a horizontal boring bar, already overcrowded with work.

To relieve the boring bar of this work, the tool illustrated in Fig. 2 was designed and the machine operation

Fig. 3—View Showing Use of Guide Adjusting Block

can now be performed on a radial drill press. As indicated, the tool consists of cutters suitable for flat seats or ball joints, the cutter in either case being guided by a spider or pilot block adjusted to any desired position by the use of set screws. In operation, the spider is set in the steam pipe

Fig. 4—Details of Guide Adjusting Block

which is firmly clamped to the base of the radial drill. The drill is started and, guided by the spider, the cutter forms a joint quickly and accurately.

Guide Adjusting Blocks

The actual operation of grinding a slightly worn guide takes from 5 to 10 min., while from 20 to 30 min. is often used, tipping the guide one way or the other to get it in position, so the wheel will grind square. The jig, illustrated

in Fig. 3, was designed to reduce this time to the minimum and make it unnecessary to bother with paper shims. By use of the set-screws shown, the guide can be tipped to any designed angle without stopping the machine or loosening up clamps.

Construction details of the jig are shown in Fig. 4. A bar of iron or soft steel, 2 in. square by 7 or 8 in. long, has a slot milled in one end and a hole drilled and tapped to take the $\frac{1}{2}$ in. by 1 in. set-screw shown. In order to permit

Fig. 5—Tool for Forming Brake Hanger Boss

tipping the guide towards the wheel, the thin shim indicated is provided and may be attached to the jig by electric welding if desired. The arrangement has proved a great time-saver.

Machining Brake Hanger Bosses

A device for holding and a tool for machining brake hanger bosses on all classes of locomotives is shown in Fig. 5. Formerly this work had to be done on a horizontal boring bar,

Fig. 6—Jig for Machining Reverse Lever Quadrants

but under the new arrangement the operation can be performed on a radial drill press. A hole is first drilled in the brake hanger at the proper place, and the succeeding operations of counter boring, turning and facing are all performed in one operation with the tool illustrated. The arrangement of this tool is plainly shown, and a similar one adapted to the

particular dimensions of any brake hanger can be provided. The only further operation necessary after facing is tapping the thread. The time now required for all the above operations is 16 minutes, and with an average of 125 brake hangers machined each month, the total saving in time is considerable.

Milling Reverse Lever Quadrants

It is common practice in some shops to lay out reverse lever quadrants and later machine the teeth on a shaper or slotting machine. With this method of manufacturing quadrants, considerable time is spent in laying out the teeth, and the work of machining them is both unnecessarily long and non-uniform in results.

To overcome these difficulties the arrangement shown can be used to good advantage. Referring to Fig. 6, the reverse lever quadrant *Q* is supported on the table of the universal milling machine by a quadrant support *A*, being firmly held in place by the set-screw shown. The radius rods *B* are adjusted to the proper length and supported on the extension *C* firmly fastened to the milling machine table. A latch operated by the latch handle *D* is provided at the quadrant support, being arranged to fit into each quadrant tooth, while the next tooth is being milled. The quadrant is thus accurately located for each tooth. By using this arrangement, the radius of the quadrant is correct, every tooth is exactly the same depth, the same distance apart, and all the labor of laying out the radius and teeth on the bench is saved with a resultant decrease in labor cost.

WELDING SUPERHEATER UNITS

BY W. EISELE

The ordinary superheater unit with four tubes and three return bends presents numerous opportunities for leakage, especially in the six threaded connections. Although the return bends are made of high grade steel and the tubes are secured by a taper thread there is considerable

trouble from leaky joints. Electric welding where the tube entered the return bend was tried in order to stop the leakage, but it was found after several trials that the weld when cooled and tested was not perfect, due to the unequal expansion of the rolled steel tube and the cast steel return bend. This difficulty has been overcome by filling the unit with water and plugging the open end with wooden plugs while welding. The water reduces the expansion to a minimum and makes it easy to get a tight joint.

FUEL OIL AS A MEANS TO INCREASED CAPACITY

Critical Boiler Plant Condition Relieved and Efficiency Improved by the Use of Fuel Oil in Place of Coal

BY C. C. LANCE

Shop Engineer, Seaboard Air Line

THE Jacksonville plant of the Seaboard Air Line provides power, light, compressed air, water and fire protection to a general shop for repairing locomotives, freight and passenger cars. It is the second in point of size on this railroad and cares for all repair work originating on the southern end of the line.

In addition to the shop requirements, power, water and compressed air are supplied to a large roundhouse and all locomotives running in and out of this terminal take water here. The roundhouse has a separate stationary boiler to furnish steam for blowing engines and similar purposes, as on account of the distance from the main power plant it was not considered economical to carry steam that far. When originally built the boiler equipment consisted of three 187 hp. Stirling boilers, arranged for burning coal, hand-fired, each boiler having its separate steel stack. An underground

creased demands for all kinds of repair work made it necessary to modernize the shops at Jacksonville and add to the machine tool equipment. This in turn required more power, additional boiler capacity and larger generators. The plant at present consists of four 187 hp. Stirling boilers in two batteries, one 252 hp. and one 274 hp. Erie City vertical water tube boiler set separately. All boilers are connected to a concrete stack 6 ft. 6 in. inside diameter, 175 ft. high, which gives a draft of 1¼-in., while the best obtainable draft with separate stacks was 0.3 in.

Power is now supplied by one 500 kw. turbine-driven alternator, one 120 kw. direct-current and one 120 kw. alternating current generator, each direct connected to tandem compound steam engines. Two 500 and one 1,000-gal. per minute underwriters' steam fire pumps supply water and afford fire protection, while one 925 cu. ft. and one 1,500

Arrangement of Oil Burning Apparatus, Seaboard Air Line, Jacksonville, Fla.

ash tunnel was provided below these boilers, which were provided with ash hoppers that dumped into buckets on narrow-gage cars which were so arranged that they could be dumped by an outside overhead electric traveling crane.

The power generating equipment consisted of two 120 kw. alternating current generators and one 120 kw. direct current generator, each direct connected to tandem compound Erie Ball engines, a 35 kw. direct current steam driven generator and one 35 kw. steam turbine. One 925 cu. ft. steam-driven air compressor and two 500-gal. per minute underwriters' steam fire pumps furnished water supply as well as fire protection. The generating equipment was run condensing with vacuum and dry air pumps, no circulating pump being installed, as the pressure from the artesian well supplying water was sufficient to carry cooling water through the condenser.

Increased Demand for Power

The increase in size and weight of locomotives being handled in the shops and roundhouse and the generally in-

creased demands for all kinds of repair work made it necessary to modernize the shops at Jacksonville and add to the machine tool equipment. This in turn required more power, additional boiler capacity and larger generators. The plant at present consists of four 187 hp. Stirling boilers in two batteries, one 252 hp. and one 274 hp. Erie City vertical water tube boiler set separately. All boilers are connected to a concrete stack 6 ft. 6 in. inside diameter, 175 ft. high, which gives a draft of 1¼-in., while the best obtainable draft with separate stacks was 0.3 in. Power is now supplied by one 500 kw. turbine-driven alternator, one 120 kw. direct-current and one 120 kw. alternating current generator, each direct connected to tandem compound steam engines. Two 500 and one 1,000-gal. per minute underwriters' steam fire pumps supply water and afford fire protection, while one 925 cu. ft. and one 1,500

Critical Situation Relieved by Oil Fuel

Due to the large increase in the cost of coal, the extremely poor quality obtainable and the difficulty in securing and keeping the labor required to fire the three shifts, great difficulty was experienced in making periodical inspections,

washing boilers and making repairs, while keeping the plant in operation. It became necessary to put two locomotives into service as auxiliary steam units, and during repair and washout times as many as three locomotives were in service. At that time there was a total connected load of approximately 1,400 hp. with a boiler plant totaling not over 1,000 hp.

With the separate stacks affording insufficient draft, poor coal and a shortage of labor it became imperative to effect some improvement in the capacity of the boilers. After a study of the situation and a discussion in regard to the probable cost of various means for increasing boiler capacity, it was decided that conversion to oil fuel in place of coal afforded the most practical means at hand. It was estimated that the initial cost of making this change was considerably less than would be required to install additional boilers and that with oil fuel the sustained capacity of the boilers could be greatly increased. However, this step was delayed and the plant continued to burn coal until December, 1919, by which time the frequent shutdowns and other operating difficulties increased until immediate relief became necessary.

Oil Burning Equipment Installed

The facilities installed for burning oil consisted of a 25,000-gal. steel storage tank and a duplicate system of oil piping leading to the pump, heating pipes being provided inside the tank and in each oil pipe line leading to the pump on account of the heavy consistency of the oil used. Each boiler was piped with steam and oil pipes with control valves located conveniently to operator's reach. Tate-Jones burners were used, modified slightly to give improved atomization of the oil and throw a better spray. The only changes made in the boilers were the building of higher bridge walls to protect the bottom drums and tubes, and slight alterations to the baffles, fire brick protections to the grates and the bricking up of all door openings.

The original plans for the oil burning system were made by the mechanical department, and the work of converting the plant from coal to oil burning was most expeditiously handled by the mechanical forces at Jacksonville.

Improvement Effected in Operating Results

Since changing this plant from coal to oil a remarkable increase in efficiency has been made as well as extensive savings in operating cost.

With the peak demand for power at present only four boilers are required to carry the load, and three have handled it successfully. At night three boilers ordinarily carry the total load and occasionally it has been cared for by two. When additional boiler power is required, a boiler can be brought from warm water to steam at working pressure and cut in on the line in 25 minutes from the time that the oil is lighted.

A marked saving has been made on account of the ease with which the oil fuel is handled and delivered to the boilers. The elimination of the ash removal, with its dirt and danger and the use of the overhead traveling crane or keeping a night crane operator on just for this purpose, has released a large force, as well as the men who were formerly required to handle coal and fire the boilers.

A statement showing the comparison of the working force required firing with coal and that required using oil is given.

Reliability and Economy

During 1919 the shut downs on account of bad coal and other difficulties amounted to 100 hours, while in the 5 months ending May 31, 1920, shut downs of only 1 hr. 45 minutes were directly traceable to oil fuel. Based on this, the shut down on account of oil would amount to only 4 hours per annum. During 1919, 15,503 tons of coal were used, costing \$5.50 per ton or \$85,266.50. For the five months ending May 31, 1920, the total oil consumption was 1,280,-

631 gallons or an average of 256,124 gallons per month. On this basis the annual oil consumption would be 3,073,488 gallons, which, at \$1.25 per bbl., amounts to \$92,204.64.

However, these conditions changed in July and the price of oil advanced to 11½ cents per gal. or an increase of 8½

			Total monthly savings				\$2,704.80
			Total labor annual savings				32,457.60

cents over the original cost. This was subsequently reduced to 6 cents per gal. The consumption of oil was carefully investigated and by better heating and atomization and by changing the draft this was reduced to approximately 178,000 gallons per month, making the present monthly oil cost approximately \$10,680.00.

The monthly fuel consumption based on the maximum demand for power is given below comparing oil and coal.

Burning coal (estimated, August, 1920, figures)	
2,250 tons @ \$6.....	\$13,500.00
Labor cost	4,832.40
	\$18,332.40
Burning oil August, 1920, figures oil 178,000 gallons @ \$0.06	\$10,680.00

Total annual approximate operating costs burning coal	\$228,179.80
Annual approximate cost burning coal.....	\$228,179.80
Annual approximate cost burning oil.....	154,018.84
Approximate annual saving in fuel and labor by burning oil....	\$74,160.96

This saving will represent six per cent on the investment of \$1,236,016.00, while the total cost of equipping this plant to burn oil did not exceed \$5,000.00.

HEAVY BRASS CASTINGS FOR RAILROAD SHOPS

Important Savings are Possible by Operating Brass Foundries in Conjunction with Railroad Shops

BY A FOUNDRY SUPERINTENDENT

HOW many locomotive days are lost annually because of the lack of brass castings, temporarily out of stock? How many miscellaneous break-down jobs could be repaired quickly if some medium for making a brass casting was available? How many tons of scrap brass, sold to an outside foundry, could be converted into brass castings at a nominal cost? The following suggestions and an analysis of the figures quoted show that there is economy in operating a brass foundry on either a large or small scale in conjunction with a railroad shop.

A railroad with 8,000 miles of track buys approximately 900,000 lb. of new driving box and rod brasses, hub plates and other heavy castings annually and sells approximately 725,000 lb. of scrap, this figure being an estimate based on actual facts. In order to arrive at a basis of comparison and compute the possible savings by making brass castings in railroad shop foundries instead of buying them the following data are used. The market price for lake copper, always quoted as a base, is 20 cents a pound. Scrap brass in most localities can be sold for 18 cents a pound. New castings are usually purchased from outside foundries at 28 cents a pound. An annual output of 725,000 lb. per year represents a daily output of about 2,416 lb. and a foundry capable of handling this tonnage would represent an investment of approximately \$13,000 in buildings and grounds and \$3,000 in equipment. In remelting and casting brass, there is a shrinkage of four per cent and the shrinkage in 725,000 lb. would, therefore, be 21,750 lb. to be replaced by purchase.

TABLE I—COMPARISON OF RELATIVE COSTS

725,000 lb. scrap brass at 18 cents.....	\$130,500
Purchased—	
725,000 lb. new castings at 28 cents.....	203,000
Net cost	\$72,500
(B) Cost of making new castings—	
Material—	
725,000 lb. scrap brass available	
21,750 lb. at 18 cents to offset shrinkage.....	\$3,915
Sand, flour, parting, plumbago, etc.....	5,430
Labor (including overhead) to convert into castings.....	9,070
Interest on investment, insurance, etc.....	1,120
Total	\$19,535
Net annual saving of (B) over (A).....	\$53,965

With a net annual saving of approximately \$54,000 shown in Table I, the saving per pound is about 8 cents. The labor charge should not go over two cents a pound but if it went to five cents there would still be an important saving. In support of a charge of two cents a pound for labor it may be stated that one molder in a nine-hour day can turn out eight driving brasses weighing 225 lb. each or a total of 1,800 lb. If the molder is paid \$1.00 an hour, this represents a cost of ½ cent a pound for direct labor. Adding ¾ cent a pound overhead and ⅓ cent a pound for shipping, handling, accounting, etc., there is a total of 1½ cents a pound. The writer is now connected with a brass foundry that is manufacturing driving brasses, hub plates, rod brasses, bushings and other heavy castings for locomotive and shop use and does not hesitate to say that, regardless of how small the castings may be, it is a poor molder who can not make them for at least one cent a pound.

Specialties can usually be purchased cheaper than they can be manufactured in railroad shops but heavy brass cast-

ings are not in this class of specialties since no extensive equipment is needed for making them. A small brass foundry, located at the principal shop on a division, and having a maximum capacity of 1,200 lb. a day, could be constructed at a small cost as shown in Fig. 1, and costs little to operate, one molder and helper handling the work. Oil is a more satisfactory melting medium than coke and if oil is used at the shop, it could easily be piped to the building and substituted for coke. As heavy casting work will predominate there is no necessity for a sprue cutter. The gates and sprues on the heavy work can be removed with a chipping hammer, which will require running an air line to the foundry. An industrial track in and out of the foundry would make for economy.

If a heavy tonnage is required and oil is available, an open flame furnace of the Rockwell, Monarch or Schwartz type should be used, as these types are capable of heating 500 lb.

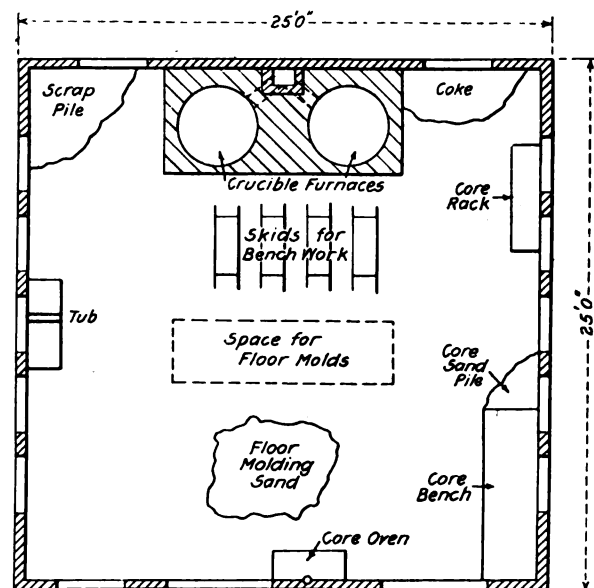

Fig. 1—Plan of Small Brass Foundry With Capacity of 1,200 Lb. a Day

every 65 to 75 min. It has been stated that a good bearing brass cannot be secured if the metal is melted in the open flame type furnace but one of the largest brass foundries in the middle west has used this type of furnace with excellent results.

Proportions of Copper, Tin and Lead

A copper, tin and lead alloy is recognized as the standard bearing bronze and while there is some argument as to the proportions, it is generally agreed that a mixture of 80 per cent copper, 10 per cent tin and 10 per cent lead is the best. The tin and lead will burn off to a slight extent, and if it is desired to maintain the standard mixture, one pound of tin and one pound of lead should be added to each 100 lb. of scrap put into the furnace. Some railroads specify the following mixture: 79 to 81 per cent copper, 9 to 11 per cent tin, 9 to 11 per cent lead, not less than .0025 phosphorus. (In order to maintain .0025 per cent phosphorus, .0075 must be added to the furnace charge on account of

shrinkage.) Phosphorus acts as a flux in the metal and not only cleanses it but changes the structure of molten brass from a creamy consistency to a watery one. One ounce of phosphorus to a ladle will do this. It also changes the color of the molten metal from a light pink to a greenish pink.

While phosphorus is decidedly hard to handle in brass casting work, it, nevertheless, is a great factor in amalgamating the metal, as a casting in which phosphorus is used has a finer grain than one from which it is omitted. The objectionable feature is that the molten phosphorus mixture

to be some slag. This slag will therefore appear in the crown or top of the brass instead of on the wearing surface. Fig. 2 shows the position of the pattern, gate, sprue, etc.

It will be noted that the sprue is heavy while the runners leading from the sprue are light. It is found to be good

One air chipping hammer	One air grinder

has a tendency to eat into the sand and make a rough casting but experience teaches ways to overcome this difficulty.

Directions for Melting and Pouring

If the crucible type furnace is used and the casting to be made weighs in excess of 180 lb., a 240 lb. capacity crucible is needed. The scrap metal should be put in the crucible and brought up to about 1,975 deg. F. This temperature causes a free, liquid content. About 15 minutes before lifting the crucible from the furnace, one pound of tin and one pound of lead should be added. This should be melted down and the heat brought up to 1,975 deg. again. The molten metal must be stirred thoroughly in order to get the lighter metals mixed with the heavier. Lift the crucible out of the furnace and carry it to the pour-off floor. The metal should be poured at about 1,700 deg. F. A lower temperature might result in the metal freezing before the mold is filled up and a higher temperature would cause the metal to eat into the sand, more especially if phosphorus is used.

Should a pyrometer not be available, the pour-off man must rely on his vision to judge the heat. Molten metal at 1,800 deg. F. or more will bubble and present a rough surface. As it cools off the surface of the metal becomes more even and just before reaching 1,700 deg. F., a bubble will appear about the center of the pot and break, spreading over the entire surface and changing the complexion of the metal to a more creamy mass. The metal should be poured immediately after this takes place. Pour a small stream to begin with, gradually increasing the flow until it is all the sprue hole will stand. As the sprue fills up, ease off and at the finish, pour very lightly, filling up the sprue to the top. Shrinkage occurs in the metal almost immediately and it is therefore necessary to keep the sprue well filled. Small brass castings are comparatively simple to make, but a solid, amalgamated driving box brass presents many difficulties. There must be no blow holes, and the copper, tin and lead must be thoroughly mixed with no segregation.

Molding Driving Box Brasses

Equally important with the heating and pouring of metal is the making of the mold. In the first place the proper sand is essential and Albany floor sand is recommended as one of the best. After repeated tests as to position of pattern in the mold, it is generally agreed that the crown should be placed up, which puts the bearing surface down as shown in Fig 2. Regardless of the quality of metal used there is bound

practice to have considerable weight behind the flowing metal but to choke it down to a finer stream before entering the casting space in the mold.

About four inches of sand should be used on all sides and below the pattern and six inches above. Weights on top of mold will prevent the metal from floating the sand on top. The drag should first be rammed, then the cope. A hand floor rammer should be used, being careful not to strike the pattern with the rammer. Hard ramming adjacent to the pattern and easier away from it will secure the best results. After the cope is rammed and before the pattern is pulled, the cope should be thoroughly vented, using a vent iron about 3/16 in. thick (pointed on the end), being careful not to run the vents up to the pattern.

After opening the mold and removing the patterns, paint the mold with a thick layer of plumbago, using a soft camel's hair brush for this purpose. It is good practice to skin-dry the mold but not essential. Molds should not be allowed to stand over 12 or 14 hours before pouring off. The mold can be dumped in about 1 hour and 30 minutes using a wire brush immediately to remove fins and other irregularities.

There are five important things to remember about brass molding: (1) get the metal thoroughly mixed and pour off at about 1,700 deg. F.; (2) use a first-class floor sand for the mold; (3) use a large sprue; (4) pour slowly at first and then rush the metal; (5) use plumbago profusely. First-class castings can be made in a small foundry and the railroad company will save about 8 cents a pound.

DRILLING RECORDS

Production and penetration records in drilling steel and cast iron were established on October 4 at the American Foundrymen's Association convention, Columbus, Ohio, by Hercules high speed twist drills, made by the Whitman & Barnes Manufacturing Co., Akron, Ohio. The speeds and feeds used in the tests are not advisable for every-day shop use, but indicate the excessive strains that modern drills will withstand. Production records are more valuable than penetration records as showing how many holes can be drilled at one grinding.

PRODUCTION RECORDS						
Material	Size of Drill	Rev. per Minute	Feed per Rev.	Penetration per Minute	Thickness of Material	Time per Hole
Cast iron	1 in.	665	.096 in.	63.8 in.	3 1/2 in.	3 1/2 sec.
Cast iron	1 1/4 in.	309	.060 in.	18.5 in.	4 1/4 in.	13 3/4 sec.
Machine steel	2 in.	157	.045 in.	7.1 in.	3 in.	25 1/2 sec.
Chrome nickel						
Steel	1 in.	309	.030 in.	9.3 in.	3 in.	19 1/2 sec.

*A total of 43 holes were made by this drill on one grinding. First 15 in cast iron 3 1/2 in thick at 309 r. p. m. with .096 feed, then the above 28 holes in machine steel.

PENETRATION RECORDS			
Material	Size of Drill	Rev. per Minute	Penetration per Minute
Drilled			
Cast iron	7/8 in.	873	.096 in.
Cast iron	1 in.	873	.096 in.
Cast iron	2 in.	597	.096 in.
Machine steel	1 in.	665	.060 in.
Machine steel	1 1/4 in.	442	.060 in.
Machine steel	1 1/2 in.	442	.051 in.

LOCOMOTIVE SHOP ORGANIZATION AND METHODS*

A Prize Essay on the Best Method of Obtaining the Maximum Output Consistent with Good Work

BY A. F. VIVIAN

Chief Draftsman, Oudh & Rohilkhand Railway, Lucknow, India

BEFORE it is practicable to consider the method of a repair shop system or any other special factors which make themselves felt in the output of work, it is desirable to outline various general classes of repairs which locomotives may have to undergo. These may be classified as follows:—

- (1) Minor; (2) light; (3) heavy.
- (1) *Minor repairs* are work that lies within the scope of the running shed equipment and staff.
- (2) *Light repairs* are work of the nature of re-turning of wheels, lining driving boxes, overhauling motion parts, skimming up piston and valve-rods, examination of boiler, renewal of water-space stays and attention to tubes.
- (3) *Heavy repairs* is the class of work where *extensive* repairs are needed to the boiler, wheels, driving boxes, motion work cylinders and steam pipes.

Locomotives needing repairs under classes (2) and (3) only are sent into shops, which is after they have run approximately 40,000 to 80,000 miles.

Output

When these locomotives come to the shops for repairs their out-turn and the progress of the work through the shops depends mainly on the following points:—

- (1) Lay-out of works and machinery employed;
- (2) Labor; and
- (3) Standardization of locomotives.

Layout

The lay-out of the works calls for ingenuity, which only those engaged with the preparation and assembling of locomotive parts can give to the subject. The relation of one department to another as regards proximity and transport of material must have equal consideration with the fixing of plan and machines in the shops themselves, while the timing of each department, so that all may keep in step without either delays or over-production, is very important. No doubling back in the passage of the material through the various processes and machines must be allowed. "In at one door and out at the other" is ever the motto to be kept in mind from the advent of the raw material to the steam trials of the finished locomotives. The pattern shops and wheel-turning department should be located as near the foundries and forge as can be conveniently arranged.

The steel foundry is as necessary an adjunct to a large railway works as an iron foundry—the successful introduction of the small converter having made this step a desirable one in many obvious ways.

The main boiler house and power station must be in a central part of the works for steam, power and light distribution. Wherever possible, individual punching and shearing machines should be motor-driven, and in the bay devoted to machine tools—these may be driven from a main shaft coupled to a wall engine or motor. All heavier punching and shearing machines should be equipped with their own jib cranes. Arrangements for turning out regular quantities of boiler stays by automatic screw machines should be made in the machine shop. Boiler tubes are often stored out of doors, and though the tubes may show no great amount of deterioration undoubtedly they have commenced to rust in spots, and quite

likely will have to be removed from the boiler sooner than would have been necessary had they been properly cared for under cover. The life of the tube is shortened; but this is not the only loss, as there is the labor of taking the tubes out and loss of the use of the engine while removing the defective tubes, and this means time lost.

The blacksmith shop should be replete with tools and machines to meet the present-day requirements. Besides Brett steam drop stamps of 30, 20 and 5 cwt. capacity, a few 10-cwt. lifter stamps worked by hand power would be found very useful. The other machines that would be necessary are bolt and nut machines, a couple of Acme riveting and forging machines, one 3-in. Ajax, one Ryder swaging machine, two Bradley hammers, and a couple of double shearing machines.

The work of the spring maker is greatly facilitated by the use of a spring-plate preparing machine. A spring-testing machine would also be found very useful.

The machine shop should consist of complete installation of modern machine tools suitably arranged for proper sequence of work, and it is the expeditious handling of these tools that results in greatly increased output. It is very essential that there should be a well-equipped tool room fenced off from the rest of the shop, devoted to tool manufacture as well as for the making of jigs and jackets for repetition work, the grinding of lathe tools, drills and drilling cutters. All automatic and labor-saving machines should be used for repetition work required in large numbers.

In the erecting shop electric traversers should be used to convey the engines in and out of the shop, and would be in addition to the overhead cranes. A 2-ft tramway on either side of the traverser would be found useful for the conveyance of material to any bay. And as regards the equipment in general, much more attention should be given, as the locomotives of to-day have increased in weight and power and call for different methods of manufacture, and large and more powerful machines are needed to cope with the new requirements.

The stores should be located in a spot convenient to all the shops, as each has dealings with it in some way or other. A branch of the stores department should be assigned to the iron foundry, so that an accurate account may be kept of the output. Articles having thread connections should not be left exposed to the weather, as this renders them almost valueless. Nor should they be roughly handled so that the threads are broken and in many cases the entire article must be scrapped because of bad threads. Rubber hose and all kinds of rubber naturally deteriorate after it has been on hand any great length of time. This should be thoroughly understood by those handling rubber goods, so that sheet rubber and packing and hose which has been on hand longest will be used first, also that proper care may be taken of it, so it is not stored in bright sunlight or in some unusually dry place. Proper housing and storing invariably means reduced cost in handling, and hence less time, besides keeping the material in better condition for use.

The conveyance of material from the stores to the shops, or, from one shop to another, should be done by storage battery trucks, tractors and trailers. It has been estimated that the cost of operating an electric tractor is about equivalent to the daily wage of a trucker. Considering this fact, with the ability of a tractor and a few trailers to do the work

* This article, which appeared recently in the *Railway Engineer*, was awarded a first prize in a competition. Many of the suggestions which it contains could well be put into practice in American railroad shops.

of six to ten hand trucks, the economy is obvious. These powerful little electric storage machines are made foolproof, and with their use the handling problem is simplified.

The handling of materials.—A factor of great importance is the care of handling material. A great deal of money is lost and time wasted by breakage, leakage and marring of material in various ways, which unfit it for service, a great deal of which could be overcome if the material is properly handled and cared for. Every man having to do with the handling of material should, so far as is possible, be instructed as to the nature of the material, the use to which it is to be put, and the ways in which it may be damaged so that it loses its usefulness entirely, or, at least, injured so that only partial service may be had from it, and even that service is often of the kind that requires a great deal of extra attention. A little rough handling, in most cases entirely unintentional on the part of the man handling the material, causes expense away out of proportion to the value of the article itself, to say nothing of the delay.

Labor

System of work applying to locomotive repairs.—Experience shows that, before any system of despatching or scheduling of work through the shops can be affirmed, there must be, first, a predetermined route, and, second, a predetermined time limit.

With the above in view, the general outline of a working system is hereby made. In order to properly carry it out it is necessary to have a competent schedule man, with authority to check up the system, which is as follows:—

The locomotive is to be thoroughly inspected prior to entering the shops, and the schedule man furnished with a copy of the inspection report, from which the shopping schedule is prepared. Separate forms should then be made out by the schedule man, covering parts to be repaired in various shops, and furnished to each foreman. The first of these forms should show the locomotive number, class, date in and date out of shops, and, under the heading "class of work," various units of the locomotive, condensed into not exceeding 30 items, to be listed in consecutive order in which the parts of the locomotive are dismantled and erected. Space is provided opposite each of these items for the date each particular item is to be dismantled or repairs started, and the date the repairs are to be completed and erected. Space also should be provided opposite each of these items for parts of the locomotive that it is necessary to send to the machine, smith or boiler shops, for the dates these parts should be received in various shops, and the dates they are to be completed. Space also provided opposite each item under the heading of "Remarks," for "The cause of the delay," if any.

The second form, a "Daily schedule delay report" to be furnished by the schedule man to the officers in charge, this form to cover all locomotives in shop in which any part is behind schedule time. Opposite the individual engine numbers space shall be provided for the various units of repairs. Under the heading covering the units of repair, space is to be provided for a check mark to show just what items are behind the schedule and delaying the work, together with the cause.

Oxy-acetylene welding system.—This is a great asset, and a few remarks may not be out of place. The oxy-acetylene cutting process may be used in locomotive shops, both in constructional work and for cutting up old boilers, tanks, etc. In boiler work, manholes, fireholes and mud holes can be cut out of the solid plate, frequently at a cheaper rate than by punching, drilling and slotting. The rapidity with which the oxy-acetylene blowpipe has been taken up by engineers throughout the world is in itself the most striking testimony to its merit, and it is not too much to say that it affords one of the most practical and valuable methods yet discovered for dealing with work in the shops, be it either new or repair. As regards cost, much depends on the nature of the work and

the capacity of the workman, but it may be stated generally that the system compares very favorably with the cost of most riveted or brazed work not over $\frac{1}{2}$ in. in thickness.

Repetition work in locomotive shops.—One of the lessons learnt from the war is that very great possibilities exist of accurately working to standard dimensions and given limits for component parts. There is undoubtedly a future for development in the design and lay-out of tools for interchangeable and repetition production, and this is a matter which concerns the locomotive as well as other machine shops. Its application will be of a more decided character than heretofore with the standard locomotive looming in the foreground. Reliable and standard limit systems, first for manufacturing, and, secondly, for tools, are necessary to suit modern methods and for all classes of works, and these must be framed from the experience gained in the use of the several existing systems, all of which are far from perfect. Since success depends upon an abundance of special tools and appliances, improved and quicker means must be devised for making them. There is, again, considerable scope for investigation in the methods of hardening high-speed and tool steels without deformation of the metal. One of the greatest manufacturing troubles now experienced is in connection with nickel steel and case-hardened parts, and for repetition work it is more than ever necessary to resort to grinding processes, so that considerable ingenuity must be given to the order in which operations are to be performed between carbonizing and quenching of the part.

Supervision.—The general conclusion is that, to ensure the efficient and economical handling of staff and material, organization is supervision. This, of course, is no new conclusion. It is self-evident. But supervision, to be effective, must be adequate in quantity. The withdrawal of the charge hand or the foreman from his duties several times a day to answer summonses from those in authority, the preparation of reports and routine work, which could be done in much less time by persons with clerical experience, are not conducive to efficient supervision.

Supervision, to be effective, must be respected. This applies to those of higher as well as lower rank. The possession of a proper designation to indicate the character of service rendered, which will command respect from those under this jurisdiction and consideration from those in other departments with whom he comes in contact, is a necessary advantage which should be given to all in charge. Competition for supervising positions should also be encouraged by making such positions as attractive as possible, and, if this is done, it will result in securing the best material available. This is highly essential if proper standards are to be maintained.

Supervision, to be effective, must also be instructive. The result aimed at is frequently missed because of a lack of understanding. To this cause may be laid many failures both of men and plans. It is necessary, therefore, that instructions should be complete, concise, understandable, and, above all, workable. It is the easiest thing in the world to give orders, but to issue voluminous orders is to ensure their being disregarded.

As regards machine shop progress in locomotive works, it may be said that, with proper supervision and the elimination of obsolete machinery, it should be possible to reduce the size of many locomotive works considerably. It is by no means unusual to find half a dozen bulky machine tools of an out-of-date description engaged in performing work which could be more easily and more economically turned out by modern tools, while at the same time reducing the amount of labor required. The principal aim is, however, that of seeking improvements by virtue of better and more widespread supervision, so that the best use can be made of every man and every machine tool and by the employment of a system which keeps a continuous and careful watch over all that is going on within the shop.

Turret Lathe of Wide Power and Speed Range

THE turret lathe, illustrated, has been developed by the Warner & Swasey Company, Cleveland, Ohio, to satisfy the demands for a machine with greater power and a range of feeds and speeds sufficient to embrace those necessary for machining the many different metals in use today; also those feeds and speeds suitable for facing, forming and

gear blanks, long drilling operations in the solid, taking heavy facing and forming cuts, and other work which often occurs in railway machine shop practice.

Heavy Duty Carriage

View Showing Arrangement of Gears in Head

cutting off operations on all diameters within the capacity of the machine. The machines have been thoroughly tested under conditions ordinarily encountered in shops and are said to have proved especially valuable in machining alloy steel

One of the most interesting features of the new turret lathe, is the specially constructed geared head. This head consists of steel gears of coarse pitch and wide face, run-

Warner & Swasey No. 6 Geared Head Turret Lathe With Standard Cutoff

ning in oil. Two gear sets are mounted on the front shaft, while the third set and the reverse friction clutch are mounted on the back shaft. This construction is reported to give four times the power of the ordinary geared friction head of the same size machine and double the power of the double friction back geared type. With all of this increased power, less effort is required to move the controlling levers and the machine is easier to operate. The oil bath which oils the gears also lubricates the bearings.

Twelve spindle speeds and reverse are secured by the construction of the geared head which makes possible the use of the particular speed on any one job that will give the best result. It is believed that this turret lathe offers a sufficiently large number of different feeds and speeds to provide flexibility and afford the correct feed and speed for any ordinary machine operation. Another advantage of the geared head construction illustrated is its adaptability to various types of motor drive, including motor drive by means of gears, chain, or belt drive with an idler to the driving shaft.

The turret lathe can be furnished with a standard type cutoff or with a new heavy duty carriage valuable for taking heavy cuts and in heavy forming operations. The range of six power cross feeds provides for all ordinary facing, forming and cutting-off feeds. The gears in the feed box controlling the carriage, as well as in the carriage apron, are of special steel designed to withstand all ordinary stress without breaking or undue wear. If desired, a square turret to carry four cutters may be substituted for the front tool post. The turrets are the same as ordinarily furnished with Warner & Swasey turret lathes and can be equipped with power feed, having four changes.

The new turret lathe is made in two sizes, the No. 4 having a capacity to take round bar stock up to 1½ in. in diameter. The swing over the bed is 16 in., over the cross slide 7 in., and the possible length that may be turned is 10 in. The No. 6 turret lathe has a capacity to take round bar stock up to 3¼ in. in diameter with a turned length of 12 in. The swing over the bed is 20¾ in. and the swing over the cross slide is 9¼ in.

The Unit Freight Handling System

THE Trinity Freight Unit—an interchangeable metal container—designed to carry freight and partially to facilitate its transfer, has been developed by the River and Rail Transportation Company, St. Louis, Missouri. These containers are made in a number of different ways for carrying various kinds of material; with side opening doors for package freight, with top doors and drop bottom for loose bulk freight, and tanks for carrying liquids. They are de-

occurring in the more ordinary methods of handling freight.

The units are made in capacities of 2½ tons and 10 tons each and are proportioned so that five 10-ton units, or twenty 2½ ton units, or several units of both capacities, and for any of the different classes of freight can be carried on a flat car of 50 tons capacity. They are rectangular in form and are substantially constructed of steel plate rigidly reinforced with angle irons to withstand the strains due to

Trinity Freight Units—Loose Bulk-Freight Type—on a 50-Ton Capacity Unit-System Flat Car. Method of Handling at Large Terminals

signed so that merchandise may be placed in a container at a manufacturing plant, or in a warehouse, the container locked and sealed, and then transported by motor truck to a railroad, or to a waterway, where the container and its contents are transferred to a flat car, or to a boat, without rehandling the material and without incurring the risk of loss so frequently resulting through theft or from the damage

the weight of the contents and the transferring of the unit from one vehicle to another.

The complete freight handling equipment as developed by this company includes a specially constructed flat car. This car, however, differs from the ordinary type of flat car now in use on the railroads of the United States only in having provision made for clamping the containers to the car so that

they will withstand the shocks incident to train movement. These special cars may be constructed at practically the same cost as any other type of flat car. At a small cost, any flat car built in the usual way may be altered so that the containers can be secured to it, or in an emergency they can be secured by using side stakes.

Those containers designed for package freight are provided with side opening doors on two sides through which they are loaded or unloaded. This type of container is

The United States Railroad Administration adopted this system to facilitate water-rail shipment of war supplies. Twenty of the 10-ton package units were built and are said to have given very satisfactory service in the New Orleans district in handling package freight.

In later improved designs containers for handling loose bulk materials were equipped with ladders, handholds and running boards in the same manner as a box car. This type of container is constructed with top doors, through which

Trinity Freight Units—Package-Freight Type—on an Ordinary Flat Car. Method of Loading at a Small Station Where No Handling Equipment is Available

fitted with steel cables, attached to lugs at the top corners, by means of which it is lifted and placed on, or taken off of, the truck, car, or boat. To lift the entire unit a crane, derrick, or other lifting device is required and such equipment generally is installed in large freight houses, or yards, and at terminals. When such equipment is not available a portable crane of the motor truck type may be used. Therefore it is generally possible to handle the loaded container, but when, at small manufacturing plants, or at outlying freight houses, this can not be done, due to lack of facilities, the car on which the containers are placed may be run alongside a platform and the freight loaded in the same manner as in an ordinary box car.

the freight is loaded, and sometimes, with drop bottom doors for discharging the load. It may be loaded by hand or by means of an automatic bucket, or by other devices for handling loose materials. After loading the container the doors are closed—and locked if desired—and the entire load lifted by means of specially designed lifting links suspended from a spreader bar. These links engage in slotted trunnions on the sides of the container, keeping it in an upright position by means of a latch on the links. When the container is in the desired location the link latch can be released and the container overturned, or the drop bottom doors released—when the container is of that type—and the load discharged.

Train Signal Operated by Electricity

THE Delaware & Hudson has in use on a local passenger train an electric signal, taking the place of the usual air signal, and this device has been tested for over a year, giving satisfactory service. The train circuit is normally closed, so that any failure of the battery or wires would be at once revealed. The electric apparatus, an electro-magnet valve, sounds a whistle. There is a whistle, with a miniature semaphore, not only on the engine but in each car of the train, and all signals are audible and visible throughout the train. The whistle on the locomotive is loud enough to be heard readily above any conflicting noise. With

this arrangement each signal given to the engine is repeated in each car, and it is possible with a suitable code for the engineman to signal to the conductor at any time. Signals are communicated instantaneously. The train circuit is energized by four-volt gravity batteries—one in each car. The circuit controller in each car is actuated by the usual cord extending through the car, air being taken from the train line.

The train is made up of a locomotive and four cars and runs between Troy, N. Y., and Rutland, Vt., 86 miles, six round trips a week.

The connection between the cars is by means of insulated

wire in the brake hose coupling, and the man who couples the air hose by the same operation completes the electrical connection. The couplings are insulated.

Arrangement of Wiring in Hose and Coupling

The electrical connection through the hose is said to be as effective as a separate connection could be, and its cost is less. This installation was in use throughout last win-

ter and there was no trouble experienced from ice or snow.

The experiment on this short train has illustrated the advantage and practicability of such a signal on freight trains, and except for the difficulty incident to using foreign cars, the system could be adapted to the longest train. It would be available also for telephone communication between the locomotive and the caboose. Extensive experiments, continuing through the winter, were made also, two or three years ago, on the Canadian Pacific and the Canadian National.

The proprietor of this system is the United States Train Signal Company, Portland, Me., and it is patented by William E. Benn and George E. Davies.

The apparatus on the Delaware & Hudson train was inspected and tested last June by the Bureau of Safety of the Interstate Commerce Commission. W. P. Borland, chief of the bureau, reporting on this test, says that "the device is designed upon sound principles, and if properly installed and maintained is capable of giving reliable train signals."

Self-Contained Internal Grinding Machine

A MACHINE particularly adapted to the internal grinding of straight or tapered holes in parts which can be revolved when held in a chuck or on a face plate, has been developed by the Cincinnati Grinder Company, Cincinnati, Ohio. It can be used for grinding the holes in gears, cones, collars, cylinders, connecting rods, bushings and all work of like character which comes within its range. Face grinding can be conveniently done in correct relation to and in connection with the grinding of the holes on the external faces. This is accomplished by substituting a cup wheel for the usual straight side wheel, using the face of the former for grinding the shoulder and the periphery for grinding the hole.

Whenever it is imperative that the hole and the face of a part be finished accurately square with each other, both

wheel-head carried upon a sliding table having provision for longitudinal motion, but not being movable crosswise; a work-head mounted on a cross-slide in such a manner so as to provide a sidewise movement for adjusting and feeding the work to the diameter of the wheel; an automatic reverse plate mounted on the front of the base for controlling the reversal

No. 9 Cincinnati Internal Grinding Machine

surfaces must be ground at the same setting. Should separate settings be made the resultant accuracy would be wholly dependent upon the closeness of the chucking which might not be within the tolerance fixed. In face grinding the position of the wheel remains unchanged, but the work-head is traversed.

The design of the machine consists mainly of a swiveling

Rear View of Internal Grinder

of the table; a gear box, contained in the automatic reverse plate, for varying the speed of the table; an automatic feeding device connecting the automatic reverse plate with the cross slide feed; a gear box on the rear of the machine for controlling the rotative speed of the work; a truing diamond carrier always in position on the machine; a separate coolant tank with accompanying piping; and a complete set of water guards.

Entirely self-contained, the machine may be driven by a single pulley from the lineshaft; by a pulley from an intermediate or jack-shaft; or, by a motor through a silent chain and sprocket. The grinding wheel is held on a spindle carried in a cylinder, tapered on the outside and mounted in a hole of corresponding taper in the wheelhead housing in which it is secured by a lock-nut. A range of wheel-heads

from maximum to minimum machine capacity is available. Each head is a complete unit in itself, made interchangeable with all other heads. This arrangement permits of quickly substituting a head of different size when changing from the grinding of large holes to small holes or the reverse, with the additional advantage that there is no adjustment of the wheel-head required when making the change.

The forward and reverse movements of the wheel-head are obtained through the reciprocating motion of the sliding table. The direction and speed of the movement are controlled by the automatic reverse plate mounted on the front of the machine which contains a clutch of the load and fire type and a gear box supplying three changes of speed.

The work-head is capable of being swiveled for taper grinding to an angle of 45 deg. or less, the swiveling being

accomplished by means of a hand wheel at its top, through a shaft and pinion, the latter meshing with a gear segment on the circular base of the work-head itself.

Power feed to the cross-slide, which carries the work-head, is received from the automatic reverse plate through a pawl and ratchet, the former being operated from a link set in motion by the table reverse lever. The cross-slide screw is fitted with a direct reading circular scale, for indicating the amount of stock removed, and with positive stops for use in the production of duplicate diameters.

The tank, which is proportioned to hold an adequate supply of water, carries the pump. It is separate from the machine and is set on the floor immediately next to it under the main drive shaft from which a belt runs to the driving pulley of the pump. Detachable water guards are provided.

The Hulson Shaking Dump Grate

THE dump grate has always been a necessary evil in the locomotive firebox, necessary for the removal of clinkers when cleaning fires at terminals, and an evil because of the "dead" surface of the dump or drop grate, from which it is impossible to remove the accumulation of ash while the locomotive is in operation between terminals.

Hulson Locomotive Grate With the Lifting Grate Open

The effective grate area is, therefore, practically reduced by the area of the dump grate.

In order that the entire area of the grate may be uniformly effective, the Hulson Grate Company, Keokuk, Iowa, has designed a locomotive grate in which the drop grate is replaced by three finger bars in a frame which may be swung upward about a shaft journaled at the front end of the grate

Side View of the Grate Showing the Operating Connections

frames. Standard Hulson finger bars are used in the lifting frame and they are shaken as a part of the front section of the grate.

The construction of the device is simple and will readily be understood by reference to the illustrations. It will be seen that the side and center frames are recessed at the front ends, the length of the recess being sufficient to take in the cast steel lifting frames of rectangular cross-section with

trunnion bearings for the three standard finger bars. Square holes are cored through the ends of the lifting frames, which are reinforced with hubs to provide ample strength, and the frames are mounted on a 2-in. square wrought iron staff. This staff, with the lifting frames and a cast steel lifting arm mounted on it, is placed in the stationary grate frames, one end being slipped into a circular hole cored in the side frame and the other dropped into a slot in the center frame. When assembled the slot in the center frame is closed by the front tie bar.

To permit the three finger bars in the lifting frame to be shaken with the remainder of the bars in the front section of the grate, the shaker arms of the bars in the lifting

Front End of the Grate Showing the Operating Shaft and Lifting Frames

frame and those in the remainder of the section are connected independently, the two systems being united through a second connecting rod with one connection to each system. In order that the movement of the lifting frame may not interfere with the operation of the shaker rigging, the rod connecting the three finger bars in the lifting frame is extended forward so that when the finger bars are in their normal position its end is directly under the lifting shaft. The operating connection is made at this point so that when the lifting grate is open, the finger bars retain positions parallel to each other and to the grates in the remainder of the section but change their angular position relative to the lifting frame itself. Either with the lifting frame open or closed, there is no interference with the shaking of the grates in the entire section.

The lifting grate is designed to swing through an angle of over 30 deg. and provides a vertical opening between the grate and the raised fingers of about 18 in. with a considerably larger horizontal opening under the lifting frame.

The operation of the Hulson finger grates, with their freedom from slicing action on the fire, tends to reduce the amount of clinkers to be removed at terminals and the design of the fingers is such that the grates dump much more freely when the bars are moved to the full extent of the shaking movement than is possible with the usual type of finger grates. Should heavy clinkers accumulate, however, the lifting section provides a means of clearing the grate with the least possible amount of effort. After all ash and clinker which will pass through the grates has been removed by shaking, the surface of the lifting section is cleared with a hoe, the material being drawn back towards the center of the firebox. The lifting section raised and all material still on the grates is pushed forward and dropped into the ash pan. The ledges at the bottom of the recesses in the grate frames are chamfered for practically their entire length, three short lugs being left to support the lifting frames when in the closed position. Any accumulation of clinker or ash on

the ledges is thus prevented and the lifting grate will always freely drop back into place.

The lifting grate is operated from the cab, its normal position being closed, and a lock is provided to hold the operating lever in the open position when the lifting grates are raised. The possibility of the dump grate opening while the locomotive is in operation is thus entirely eliminated.

The usual location of the dump grate is at the front end of the firebox and the Hulson lifting section is designed for location at that point. Should lack of clearance under the arch in locomotives with shallow fireboxes interfere with this location, it may be placed at the rear of the firebox, in which case it swings up from the rear end, under the door.

The device is simple and requires no expensive parts. The only special parts are the two cast steel lifting side frames, the square wrought iron shaft and the cast steel lifting arm. The only machine work required is the turning of the short journals. A patent has been applied for.

Continuous Vertical Type Milling Machine

THE multiple spindle continuous vertical milling machine, illustrated, is now being built by the Betts Machine Company, Rochester, New York. The machine is provided with three spindles, but it can be furnished with additional spindles to meet any requirements of work where such a design is considered desirable. The machine is intended for heavy production milling on duplicate parts and in railway shops can be used to machine journal boxes, for example. The construction is simple and rigid throughout. The spindles are machined from steel forgings and are driven through long splines and spur gears. Each of the spindles carries a milling cutter and may be adjusted vertically by hand. A four spindle machine may be fitted with two roughing cutters and two finishing cutters, thereby completing the operation in one cycle. The power for driving is furnished by either a pulley or an individual electric motor.

The table has a flat bearing on the bed, and a split tapered bushing provides for taking up wear in the bearing on which the table revolves about the column. The table is driven through a large internal gear, all bearings being bronze bushed and all gears running in a bath of oil. Four rates of continuous feed are obtained through sliding steel gears. None of the gears is in mesh except those actually transmitting power, so there is no unnecessary wear. The holding fixtures are carried on the table that revolves continuously, and no time is lost in chucking the work as the pieces are changed while the fixture is passing from one cutter to the next. Depending on the nature of the work the machine has a production capacity up to three times as great as a single spindle machine.

The maximum distance from the table to the cutter is 21 in., the table diameter being 60 in. and the maximum diameter of the cutter 16 in. The table top is 25 in. above the floor, the total height and weight of the machine being 9 ft.-6 in. and 21,000 lb. respectively.

Betts Vertical Miller With Three Spindles

Chucking Job on New Automatic Lathe

THE No. 5 automatic chucking lathe, illustrated, has been introduced recently to the American market by Alfred Herbert, Ltd., New York. Among its advantages may be mentioned the single pulley drive making a countershaft unnecessary. All operations are automatic, except chucking. The machine stops automatically at the conclusion of the work. Being low, the machine can be set up easily and controlled from the floor without a platform. No changing

of cams is necessary for any work that can be done. Automatic speed and feed changes can be made while the tools are cutting. The head is adjustable longitudinally to allow for variations in the thickness of the work. The turret rotates at the extreme back end of the stroke. The turret is clamped automatically. The turret operating drum makes three revolutions for each forward and backward motion and is driven direct by a worm wheel without torsion. The front

and back cross slides operate independently of each other. These slides can work separately or simultaneously as required.

The headstock gear, cam drum and feed gears run in oil. All bearings are continuously lubricated, requiring little attention and assuring long life to the machine. It is possible to stop the spindle automatically at any instant, as at the end of a cut, enabling the tools to be withdrawn without

Fig. 2—Method of Tooling Automatic for Machining Clutch Gear

leaving a spiral mark on the work. The spindle restarts automatically in time for the next tool.

The more important dimensions of the machine are as follows: maximum swing over bed, 18½ in.; working stroke of turret, 13 in.; number of tool holes, 4; diameter, 2⅞ in.; maximum distance from flange of spindle to face of turret,

the method of tooling this machine for the succeeding operations on the clutch gear shown in Fig. 3.*

The gear is held on its 7¼ in. diameter in a 15 in. Coventry chuck and is located dead true by a hardened steel steady bush, which fits in the large bore. The steady bush

Fig. 3—Details of Clutch Gear

is lined with phosphor bronze and serves to pilot the boring bars used in the various operations.

The large shoulder and end are first faced with tools,

Fig. 1—Alfred Herbert No. 5 Automatic Chucking Lathe

34 in.; minimum distance, 15 in.; diameter of turret, 11¼ in.; turret faces, 7⅞ in. by 5 in. There are seven automatic turret feeds from 16 to 144 revolutions per inch of feed. Automatic cross slide feeds are provided from 40 to 366 revolutions per inch of feed. The total speed range is from 14 to 411 r. p. m. The time for one cycle of the machine at high speed is 48 sec. The time required to rotate the turret one station is 1.1 sec. The machine consumes about seven horsepower under full load. Reference to Fig. 2 shows

reference 1, Fig. 2 in the tool box on the independent cross slide. At the same time, the turret is moving forward and rough turning the 4¼ in., 3⅜ in. and 2 25/32 in. diameters and opening up the 52 millimeter ball race diameter. These operations are performed by tools, reference 2, held in a combination tool holder bolted to the turret.

The second turret face carries tools, reference 3, which take

*The first machine operations on the clutch gear, illustrated, were performed on a turret lathe as described on page 669 of the *October Railway Mechanical Engineer*.

a second cut in the bore and finish cuts on the outside diameters machined by the first set of tools. At the same time the back cross slide comes in carrying tools, reference 4, in the combination tool box, and forms the small groove, finish faces the flange and forms the radius on the end. Tool, reference 5, then comes into action and forms the radii on external diameters and chamfers the bore. The

final machining operation consists of sizing the $1\frac{1}{8}$ in. and 52 millimeter bores with the floating cutters, reference 5. The limits in the bore are to .0005 in. and on the external diameters to .001 in.

The total machining time for this operation is fifteen minutes, giving a total time of forty minutes for the complete gear.

Vacuum or Pressure Pump of New Design

AN interesting and ingenious application of motions has been introduced in the vacuum or pressure pump, illustrated, which has been placed on the market by the Crescent Sales and Engineering Company, Detroit, Mich. The motions are produced by two cylinders, one the Roto-piston, being enclosed in the other and touching it at only one point as they are mounted on different axes. The inner cylinder is revolved at the same angular speed as the outer by cranks connecting the two cylinder heads. The throw of the cranks allows the Roto-piston to maintain contact with the outer case in an apparently eccentric motion which is, nevertheless, completely balanced.

The crescent-shaped space between the cylinders is sealed at its ends by the contact of the cylinders and at another point by a vane which slides in the Roto-piston and maintains contact with the outer cylinder. The crescent-shaped working chamber remains fixed in revolution; the cylinders roll past it and the vane moves through them, displacing the space as positively as in a reciprocating pump although the motion is rotary and continuous.

Friction is small because of the few sliding contacts and the pump weighs only 150 lb. although guaranteed to create a vacuum of $\frac{1}{2}$ in. of the barometer or 15 or more lb. pressure per sq. in. The pump has no valves and is self-cooling. Wearing surfaces are liberal and special features of the construction, allowing compensation for wear at these points, add greatly to its durability. In railway service, the pump can be used for spraying disinfectants, vacuum cleaning of cars, vacuum lifting of material, blowing torches, blowing heat treating furnaces and vacuum chucking.

General Utility Roto-Piston Pump

Cutting Oil Filtration and Sterilization

MACHINE tool lubrication is of proven importance, otherwise there would not be a demand for such a large number of different cutting oil liquids and compounds. It was not so long ago that the ability to increase production by liquids applied to cutting tools was recognized and water was the first liquid tried. A little experience, however, proved that a mixture of soda and water was more satisfactory all around, as the tendency to rust and corrode was largely overcome. A still further advance was the use of a cutting fluid which had not only the cooling properties necessary to absorb excess heat, but lubricating qualities as well, to decrease the power consumed and speed up production.

With the production of a cutting oil which would serve the double purpose, there came the increased cost of this item and necessity of conserving it; also, the need of an equipment to filter and sterilize the liquid, thus reducing oil expense and promoting high speed operation. A good idea of the appearance and construction of a filtering and sterilizing system designed to meet this need by S. F. Bowser & Company, Inc., Filtration Engineers, Fort Wayne, Indiana, can be gained from the illustration. Tested principles of screening, precipitation, filtration and sterilization are said to be combined in a commercial and practical manner and systems essentially like the one shown have been in service for several years, giving good results.

In operation, the system can be adapted to prevailing conditions and arranged to accomplish the work required. From

S. F. Bowser Filtering and Sterilizing System

the machines and clip separators, the oil, either by gravity or special provision, is delivered to the filter and sterilizer which automatically removes foreign matter. After going through a series of compartments, screens, filtering devices, etc., the liquid is delivered to the filter tank, which acts as a temporary storage. From this tank, the oil is returned to

the machines practically the same as new oil and used again. While the filtering process, which is automatic, is under way, the oil is also-sterilized, which tends to eliminate obnoxious odors and prevent infection, thereby preserving the health of the employees. By this conservation, a better grade of oil can be used which will not rust the work or tools.

Shock Absorber for Refrigerator Cars

IN 1914, a device known as the Cutler-Monesmith shock absorber was developed by George E. Cutler, New York, and B. L. Monesmith, Cresco, Iowa, for the purpose of reducing egg breakage in shipment. The device was adapted for refrigerator cars or sheathed freight cars and could be

involved was amply demonstrated by the condition of the Santa Fe refrigerator despatch car No. 8650, which arrived in New York recently loaded with eggs from central California and equipped with the Cutler-Monesmith shock absorbing device. This car was one of five test cars. As shown in the illustration, there is a space in the center of the car which was occupied by 2-in. by 4-in. bracing. As soon as the car door was opened, it was evident that the bracing had collapsed due to a severe shock, and caused some damage.

Twenty-three cases of eggs were broken, due to the collapse of this bracing, and not caused by any defect in the shock absorber. The demonstration of the efficiency of the shock absorbing device was more convincing because of the evidence of exceptionally severe and violent usage of the car. It was felt that with a proper center bracing or filler in car No. 8650, practically no breakage of eggs would have occurred in spite of the heavy shocks. Results of the test vindicated the contention of Messrs. Cutler and Monesmith that the load must be made rigid within the confines of the movable carriage and be sufficiently separated from the car sides to permit forward and backward oscillation without contact.

The floor racks are made of 1-in. by 4-in. slats and 2-in. by 4-in. stringers. It will be noticed in the line drawing that the lowest spring is greater in free length than the highest one. This gives a greater spring compression at the bottom of the buffer, where it is most needed. The length of the floor section is made such as to cause the front racks or buffers to stand in a vertical position. The width of the buffer is $\frac{3}{4}$ in. less than the interior width of the car. The buffers are ordinarily 5 ft. 8 in. above the floor of the car and $1\frac{1}{2}$ in. less than the width of the car. All buffers

Details of Buffer Construction

used for shipping other products than eggs. The original arrangement consisted of a loose floor racking supported on pieces of 2-in. pipe with spring buffers at either end of the car to absorb the shock. This arrangement was some-

Phantom View of Cutler-Monesmith Device Applied to Refrigerator Car

what crude and recent developments are shown in the illustrations.

The principle of the improved shock absorber is the same as that of the first device, namely, the load is held as a unit within the car on a movable floor, the shock being absorbed by spring buffers at either end. There must be no projections on the interior of the car sides to interfere with lateral movement of the load. The correctness of the principle in-

and floor racks receive one coat of linseed oil, well rubbed in. The metal work in the device is treated with an anti-rust process.

The rollers shown are made of extra heavy $1\frac{7}{8}$ in. pipe, the journals being welded into each end of a steel plug $1\frac{1}{4}$ in. long. The journals are $\frac{3}{4}$ in. in diameter. The bearings are ordinarily made of malleable steel castings designed to support the load with a generous factor of safety. The

springs are made of spring steel wire, oil tempered and carefully coiled to correct form and dimensions. Each end of the buffer is provided with two clean-cut openings, or hand-holes, of sufficient size so that the ice bunkers may be readily cleaned. The hand-holes have a hinge at the bottom and lag screws at the top as illustrated.

Another important advantage of this device is the fact that the load rests a few inches above the floor of the car and there can be no damage due to water. The device is adaptable to use for other merchandise and food products, being by no means limited to the transportation of eggs. In case heavier material is to be shipped, it would only be necessary to furnish springs of greater tension and possibly insert two extra springs in the bottom row. The ideal spring

tension would be one sufficient to gradually return the load to its central position after a shock, and thus have it ready for the next shock.

Greater production of all kinds of material, including food products, is the compelling cry of the times, but "a penny saved is a penny earned" and the conservation of food supplies is just as important as their production. An idea of the magnitude of egg breakage and resultant loss may be obtained from a statement given out by competent authorities. During the months of May, June, July and August last, American railroads were obliged to pay one shipper alone \$40,000 in damages to eggs shipped across the continent. The importance of any device tending to eliminate or reduce this breakage is therefore apparent.

Release Connection for Car Couplers

THE chain and clevis connection between the uncoupling rod and the coupler lock is troublesome to maintain in proper condition and has been responsible for a large proportion of the violations of the Safety Appliance Act falling under the classification of inoperative couplers. As a great many cars now in service are equipped with uncoupling rods to fit clevis connections, there is a large field for devices that will avoid the defects of the former standard M. C. B. design and can be applied without changing the rod.

A car coupler release connection that can be applied quickly to any M. C. B. coupling lever has been invented recently and a patent on the device has been issued to Edwin Jones, passenger car foreman, Baltimore & Ohio passenger station, Cleveland, Ohio. As shown in the illustration, the connection is applied or removed simply by turning the lock fully over, when the center arm of the uncoupling lever is raised up to the connection hooks. There is no prying open or closing up of open eyes, hooks, or any other parts and the device can be applied or removed as many times as desired without weakening or destroying it. The E. D. J. O. coupler release connection, as it is called, is stated to be reliable, durable and efficient in action. Its simplicity and ease of application will be appreciated by car repairmen who have been used to the older types of connection.

Easily Applied Coupler Release Connection

Trailer Attachment Applied to Transveyor

THE attachment illustrated enables the Type G transveyor manufactured by the Cowan Truck Company, Holyoke, Mass., to be used as a trailer behind electric storage battery trucks, either singly or as a train. The at-

Cowan Transveyor Trailer Attachment and Safety Latch

tachment fits onto the front wheel and hitches to the draw bar on the rear axle of the transveyor ahead of it, or the draw bar of the electric truck. No change in the construction of the transveyor is necessary except a longer axle for the front wheel fork. The draw bar is applied to the rear axle of any transveyor without taking off the wheels, as it merely slips over the rear axle. Both the attachment and the draw bar are steel castings and will stand up under any ordinary conditions.

In this arrangement the shortest possible connection is provided for, so that the train will be no longer than is absolutely necessary. The truck wheels follow in the same track and the turning radius is so short that a train of ten trucks has been turned in a circle on a twenty foot roadway. Plenty of up and down play is allowed so that there will be no binding as the machines go over the door sills or the top of steep inclines.

A safety handle latch has been devised for the transveyor as indicated in the illustration by arrows. This latch is made of tempered steel attached to the top of the king pin of the front wheel fork. It has two leaves, stiff

enough to prevent the handle from falling down. As the handle is thrown back into a vertical position, it slips over the spring, and no amount of jarring will cause the handle

to fall forward. The latch, however, does not interfere with the free movement of the handle, when it is necessary to bring it down to manipulate the transveyor.

Inserted Tooth Face Milling Cutter

A NEW inserted tooth face milling cutter known as the type A cutter has been developed recently by the Lovejoy Tool Company, Inc., Springfield, Vt. The cutter is of the inserted tooth type, being recommended for all face milling operations where the depth of cut does not exceed 9/16 in. The cutter bodies are made of a tough hardened steel, designed to withstand the most severe usage. The teeth are positively locked by means of taper pins, as illustrated. This arrangement is stated to prevent any possibility of slipping or loosening under heavy or intermittent cuts. The teeth are made to gage and are interchangeable with a liberal amount of stock provided for wear.

The ease with which the teeth are adjusted forward to compensate for wear, or replaced with new ones when necessary, is an obvious advantage. It is stated that this type of body is well adapted for holding stellite and can be furnished with stellite teeth when desired. The time consumed in grinding a cutter of this type is reduced to a minimum.

The new type A cutters are made in five sizes from 6½ in. diameter to 10 in.

Lovejoy Inserted Tooth Face Milling Cutter

Milling Attachment for Use on Lathes

A COMPARATIVELY simple milling attachment which can be applied to engine lathes has been placed on the market by the Hinckley Machine Works, Hinckley, Ill. This attachment is adaptable to a great variety of light milling work, such as milling keyseats for both plain and Woodruff keys, squaring the ends of shafts, sawing, splining shafts, splitting bushings, drilling, boring, and numerous other jobs.

The attachment is shown in the illustration and may be applied to lathes of any make and size from 12-in. to 24-in. swing. The device swings with the compound rest to bring shafts in the right position to cut keyseats. The steel V-block lines up the shaft, which is held firmly in place by two set screws. In order to prevent marking the shaft, the block shown in the lower part of the illustration is usually placed between the shaft and the screws. A Woodruff keyseater cutter is held in the lathe spindle as shown and mills the key way.

The low center of oscillation makes the device rigid, a feature which is also secured by the use of two substantial bolts holding the attachment firmly to the cross-slide saddle. The vertical hand feed of the attachment is seven inches up and down, the cross and length feeds being the feeds of the lathe. Vertical feed is provided by means of a hand-operated ball crank and is graduated to thousandths of an inch. It is graduated to swivel in a vertical plane to 180 deg. This device can be provided ready for application to any engine lathe by submitting the dimensions of the toolpost saddle with the order.

Attachment Set Up Ready to Cut Keyseats

A New Duff Automatic Lowering Jack

THE Duff Manufacturing Company, Pittsburgh, Pa., has recently added to its line of automatic lowering jacks a new jack (No. 339) designed especially for removing and replacing couplers and for bridge work. A capacity of 15 tons and a lift of 11½ in. are provided. The jack has

the simplified reversing mechanism of the Duff jack (No. 229) previously described in detail on page 531 of the September, 1918, *Railway Mechanical Engineer*. A fine-tooth rack and the reduction of friction makes the jack operation easy, and long life is ensured by strengthening

the jack at all points where experience has shown it to be desirable. The jack is single acting, raising only on the down stroke of the operating handle. Another advantage from the storekeepers' point of view is the fact that all parts

of the new jack except the rack and base are interchangeable with the corresponding parts of previous car and journal jacks, Nos. 219, 249 and 248. This will eliminate the necessity of carrying so many different parts in stock.

Rotary Hack Saw Cuts Round Holes

THE Misener rotary hack saw has been developed recently and proved a satisfactory tool for cutting round holes in metal, wood and other kinds of material. As shown in the illustration, the principle of the device is simple, since it consists of a holder, driven either by a motor or by a common bit brace, arranged to hold a hack saw blade bent in the form of a circle. Concentric grooves in the holder provide means of obtaining holes of different sizes and a small drill at the center serves to hold the tool on center. With a set of the hack saw blades furnished with this tool, it is possible to cut holes from 1 in. to $3\frac{1}{2}$ in. in diameter. This rotary hack saw is light and portable and should save its cost many times over in the reduction of time previously required to drill, file and ream round holes. The device is of special value to electricians and can doubtless be used to very good effect by tinsmiths in locomotive shops who have to cut many holes through jacket iron for pipes, etc. Carpenters in the cab shop will also find many excellent opportunities to use this ingenious device. John Conolly, Rochester, N. Y.,

is exclusive sales agent for the Misener rotary hack saw and is prepared to make deliveries at an early date.

Misener Rotary Hack Saw

Convenient Type of Bench Drilling Stand

THE bench drilling stand, illustrated, has been put on the market by the Black & Decker Manufacturing Company, Baltimore, Md., and is designed to take the $\frac{3}{8}$ in., $\frac{1}{2}$ in., $\frac{9}{16}$ in., $\frac{5}{8}$ in., and $\frac{7}{8}$ in. portable electric drills made by that company. The bracket carrying the drill can be raised or lowered on the vertical column and is secured in any desired position by means of a split collar and clamping screw. The drill may be swung clear of the base, making it possible to use this stand for such work as drilling holes in the ends of shafts, and other work too high to be drilled on the bench.

Both vertical and horizontal adjustment are secured by means of the clamping screw. An extra long feed lever gives a feed ratio of six to one and 100 lb. pressure applied to the handle will feed the drill under 600 lb. pressure. This facilitates fast work with little effort. In the base of the stand, there are six tapped holes to accommodate $\frac{1}{2}$ -in. studs, used to clamp the work in place. One stud with a nut and clamp is supplied with each stand. The stand is exceptionally rigid in construction, the vertical column being a solid steel shaft $1\frac{7}{16}$ in. in diameter. The base is provided with four holes for fastening the stand to the bench by means of $\frac{3}{8}$ -in. lag screws.

The distance from the bottom of the base to the top of the vertical column is 30 in., the vertical adjustment of drill being 12 in. The distance from the center of the drill bit to the circumference of the vertical column is 7 in. The vertical travel of drill when operated by the feed lever is 4 in. The net weight is 70 lb. The stand is shipped complete with an adapter block. The sizes and types for which adapter blocks are suitable are stamped on the blocks and only Black & Decker portable electric drills of corresponding sizes and types can be used. Perhaps the main advantage of the drilling stand, not previously mentioned, is due to the fact that radial drills and large drill presses are usually overcrowded with work and by doing many small drilling jobs at the bench, large drills are relieved of that much work.

Black & Decker Bench Drilling Stand

Adaptable Drill Clamp and Support

AN efficient device known as the Canton drill clamp and support has been placed on the market recently by the Poyser-Bucher Company, Canton, Ohio. This tool is intended for use on bridge and construction work where many holes have to be drilled in I-beams. Formerly such work was done with the drill held by a goose-neck, or old man, which is a more or less inefficient and expensive method because the length of time required to adjust the old style goose-neck was considerable. Also a separate adjustment had to be made for each hole.

The operation of the drill clamp and support illustrated is readily understood. By loosening up the nut and casting at the left, the support can be slipped along and a hole drilled at any point in the web desired. Should it be desired to drill holes in the top of the I-beam, the long shaft is removed and put through the support in a position at right angles to its present position. The U-bolt is then tightened around the shaft and holds it at the desired height, no further adjustment being necessary for drilling as many holes as may

be desired in the top of the I-beam. The total saving in time when drilling several hundred holes is surprisingly large.

Canton Drill Clamp and Support

Recent Improvements in Cincinnati Planers

SEVERAL recent improvements in the planers manufactured by the Cincinnati Planer Company, Cincinnati, Ohio, are worthy of special attention because they mark the more extended use of the box section in planer construction. The box arch, illustrated in the upper part of Fig. 1, was designed primarily to add strength and stiffness

Fig. 1—Views Showing Box Section Construction of Planer Arch and Cross Rail

to the housings and the upper part of the planer. This box arch is cast in a strictly box form, as shown. The top of the housings of the planer have been widened to accommodate the arch and ample provision is made for securely bolting the arch in place at all four corners.

The box form of construction has also been extended to the cross rail. Instead of the more familiar type of curved back, the cross rail is now constructed, as shown in Fig. 1, with a deep heavy box section which is well ribbed. It is stated that this construction adds rigidity and firmness to the machine and makes it possible to take considerably heavier cuts.

An automatic stop for the rail elevating and lowering device is clearly shown in Fig. 2, and provides a valuable safety feature which combines simplicity and convenience. In operation, the elevating device is released by the movement of a vertical stop rod, shown at the left side of the housing. This stop rod is provided with two stop collars adjusted at the limits of safe vertical travel of the cross rail. A third collar can be adjusted to stop the downward movement of the rail at any position within its range of travel. A new style saddle is shown with provision made for clamping the upper part of the swivel securely against the face

Fig. 2—Automatic Safety Stop for Elevating and Lowering Device

of the saddle by means of a clamp. This arrangement is designed to prevent the possibility of breakage to the clapper box. Rapid power traverse for moving the rail head into position quickly and easily is another advantage claimed for this planer.

Grinding Wheel Dresser for Fine Wheels

IT is essential that grinding wheels be kept in the best possible cutting condition because tools cannot be properly ground with wheels that are either out of round or clogged. This is especially true in tool room work where milling cutters, reamers and all sorts of cutting tools must be accurately ground.

With these facts in view the Oliver Machinery Company, Grand Rapids, Mich., has developed the Metcalf grinding wheel dresser, which is recommended and designed primarily for fine wheels 1 in. or less in thickness. This device makes it possible to turn a bevel or V-edge, or true up a square edge quickly and effectively. It prevents chipping or breaking away of the grinding wheel. On large coarse snagging wheels the Metcalf dresser is intended to supplement the work of a diamond dresser and assure a smooth grinding surface. It is equally adapted for surface and cylindrical grinding wheels and can be used in places where the space is limited.

Three styles of grinding wheel dresser are provided for ordinary shop use. Type A is recommended for turning square, round, bevel or V-edges on wheels 1 in. or less in thickness. This is the most commonly used type and is very convenient for tool room use. It is shown in the illustration with the two ball handles. Type B, not illustrated, is provided with a shank which may be fastened in the tool post. Type C is designed for working in tight places, as, for

example, grinding the bevel on the small wheel shown. It will dress the sides on straight or dished wheels and dresses special shapes internally.

Two Types of Oliver Grinding Wheel Dresser

Electrically Driven Tool Grinding Machine

THE self-contained electrically driven grinder illustrated is particularly rugged in construction and therefore adapted to the more or less severe usage accorded machine tools in railway shops. Vibration is reduced to a

United States Electrical Tool Grinder

minimum by providing the large base shown, with a column of generous proportions.

Power to drive the grinder is furnished by a 5-hp. direct

current motor enclosed within the casing. Ample provision is made for the inspection of the motor, which is protected from possible injury due to falling articles by the heavy iron casing. The motor was designed especially for grinder service, being a variable speed motor with speeds ranging from 1,100 to 1,600 r.p.m.

Arrangements for increasing the speed as the grinding wheels wear down are made by means of electrical equipment shown in the pedestal of the grinder. The machine is started and stopped by means of two push buttons and is furnished with S. K. F. ball-bearings throughout. Grinding wheels 18 in. in diameter with 3 in. faces are to be used with this machine.

Wheel guards of the hinge door type, amply strong to guard against accident, are provided for the grinder as shown; also exhaust connection for carrying away the particles of dust and metal. Adjustable rests are provided for the support of tools while being ground. The grinder is manufactured by the United States Electrical Tool Company, Cincinnati, Ohio.

RULES FOR HANDLING DIE-BLOCKS.—The following rules for the handling of die-blocks are given by the Pennsylvania Forge Company, Bridesburg, Philadelphia, Pa., in a recent publication entitled "Die-blocks":

1. Never harden a block unless the impression has been carefully polished. Rough impressions are the cause of many failures.
2. Never charge cold blocks into a hot furnace.
3. Never rush heating operations. Take plenty of time and save trouble.
4. Never quench a block that shows uneven heating. If properly "soaked," the color and temperature will be the same throughout.
5. Never allow a block to become dead cold in the bath.
6. Never postpone the drawing of a die-block. Draw it immediately after hardening.
7. Drop-forging dies should never be stored in a cold, drafty place after hardening.

duction of the ad valorem duty from the 31.25 per cent, which manufacturers of other nations must pay, to 11.25 per cent. This gives American manufacturers a decided advantage over foreign competitors. Some Cuban railways are, however, under British control and there is a disposition to favor British bidders when it can be done without increased cost.

Shop Construction

Atchison, Topeka & Santa Fe.—A contract has been let by this company to J. E. Nelson & Sons, Chicago, to construct a machine shop at Albuquerque, N. Mex., to cost approximately \$1,250,000. This shop will be the central structure of a group of six other buildings to be constructed later. This building will be constructed of steel and glass and will have a composition roof and a mastic floor. There will be 26 engine pits. It is to be heated by a fan system placed in the upper structure.

China Standardizing Its Railways

The Chinese Ministry of Communications is making good progress in determining standards for the government railways of that country. The Commission on Railway Technics was organized in 1918 to make observations and recommendations regarding standards for all phases of railway work. It is expected that, once uniform materials and equipment are decided upon, those manufacturers who can supply the specified materials most efficiently will secure the Chinese trade. The Ministry desires to have some of the railway supply industries locate in that country if possible.

Chilean State Railways Poorly Equipped

Reports from Valparaiso say that the Chilean State Railways have reached their maximum carrying capacity, which meets about half of the transportation needs of the country. Owing to the difficulty of negotiating a foreign loan for the purchase of equipment abroad, the government is being urged to stimulate the manufacture of railway supplies in Chile. It has been about eight years since new equipment in large quantity has been purchased. In the meantime needs for new rolling stock to provide for additional business and for deteriorated equipment have grown apace.

Freight Car Orders

The Northern Pacific has ordered 93 caboose cars from the Pacific Car & Foundry Company.

The Gulf Coast Lines have ordered 500 box cars and 50 tank cars from the American Car & Foundry Company and 400 gondola cars from the Mount Vernon Car Manufacturing Company.

The Western Pacific has ordered 700 50-ton composite general service cars from the Pressed Steel Car Company.

The Wheeling & Lake Erie has ordered from the Standard Steel Car Company 1,500 50-ton steel gondola cars; from the Pressed Steel Car Company, 500 50-ton steel gondola cars and 500 40-ton box cars; and from the American Car & Foundry Company, 500 40-ton box cars.

Air Brakes on Swedish Railways

It is now announced that the Kunze-Knorr air brake, a German invention, with which the rolling stock of the State Railways in Sweden are to be equipped, will involve an expenditure of no less than 30,000,000 crowns, which at normal rate of exchange represents \$8,150,134.

The railway officers estimate the annual saving from the use of this particular air brake at 5,500,000 crowns, or \$1,474,530 at normal exchange, and this because of the consequent reduction in the number of railway employees. These Kunze-Knorr air brakes are to be made in Sweden, Aktiebolaget Nordiska Armaturfabrikerna, at Lund, having made a contract with the German company to manufacture them.

The Swedish private railroads have been reluctant to adopt air brakes, but it is probable that sooner or later they will follow in the footsteps of the State Railways. It would, therefore, be well, says Consul General Dominic I. Murphy, who sends the above information to Commerce Reports, for American manufacturers of air brakes to get in touch with the private railroad companies in Sweden, as it is quite certain that the German company cannot undertake to equip them at least for a year or two.

School for Railway Employees in Berlin

BERLIN, Germany.

A school for railway employees was founded in Berlin about a year ago and the first annual meeting was held on July 15, 1920. At this meeting it was stated that owing to the success of this school, 20 branch schools were opened in the Prussian-Hessian railroad district during the year and that about 18,000 pupils are registered. It is planned to open a further 36 schools in the near future. It is the aim of the school to give all progressive employees the possibility of further education. It therefore has established courses on general educative subjects given by well-known teachers of high schools and universities, and in addition special courses on railway matters. As both the workers and the employees' trade unions are in favor of and are co-operating in the scheme, the government has declared its willingness to promote and further the movement as far as possible.

Modifications in Prices in Interchange Rules

The mechanical Section of the American Railroad Association has issued circulars S III-166 and S III-168 announcing changes in the labor rates for repairing foreign cars and in the maximum amount of labor chargeable to cars under Rule 120. Circular S III-166 reads as follows:

Since Supplement No. 3 to the 1919 Rules of Interchange was prepared and approved, the labor rates paid by the railroads to employees engaged in car repairs have been increased. Therefore, effective September 1, 1920, the rates to be charged for labor repairing foreign cars shown in Supplement No. 3, 1919 Rules of Interchange, effective same date, are modified as follows:

Freight Car Code.—Rule 101, Item No. 172, labor rate for ordinary car repairs; changed from \$1.00 to \$1.20 per hour. Rule 107, Item No. 443, labor rate for repairing and testing steel tanks of tank cars, changed from \$1.25 to \$1.45 per hour.

Passenger Car Code.—Rule 21, Item No. 19, labor rate on lubrication; changed from 70 cents to 90 cents per hour. Rule 21, Item No. 20, labor rate for repairing passenger equipment cars; changed from \$1.10 to \$1.30 per hour.

These labor charges, in addition to including the actual labor cost of performing the work, include the following items of indirect expense: Wages of foremen, work inspectors, clerks, laborers, etc., working on freight repairs.

Proportion of the expense of operating power plant and of wages of shop or gang foremen, shop clerks, etc., whose time is not charged direct to freight repairs.

Shop switching, including repairs, depreciation, interest, taxes, fuel, lubrication, water, other supplies, fuel station and enginehouse expenses, wages of enginemen and firemen, switch crews and switch tenders.

Proportion of salaries and expenses of G. S. M. P. and M. clerks, S. M. P. and M. and clerks, master mechanics and clerks and general foremen.

Circular III-168 increases the limits for labor in Rule 120, as shown in Supplement No. 1 to the 1919 Rules of Interchange, issued March 1, 1920, to conform with the increase in the labor rate for car repairs, as shown in Supplement No. 3 to the 1919 Rules and Circular No. 166, effective September 1, 1920:

Rule 120. Repair limits for labor:

REFRIGERATOR CARS

Wooden, with trucks of less than 60,000 lb. capacity.....	\$108.00
Wooden, with trucks of 60,000 lb. capacity and over.....	180.00
Wooden, with trucks of 60,000 lb. capacity and over, equipped with metal draft arms extending beyond body bolster, continuous metal draft arms, transom draft gear, metal center sills, or steel underframe	270.00

HOUSE AND STOCK CARS

Wooden, with trucks of less than 60,000 lb. capacity.....	45.00
Wooden, with trucks of 60,000 lb. and over.....	108.00
Wooden, with trucks of 60,000 lb. capacity and over, equipped with metal draft arms extending beyond body bolster, continuous metal draft arms, transom draft gear, metal center sills, or steel underframe	225.00
All steel, or steel superstructure frame with steel underframe.....	315.00

GONDOLA AND HOPPER CARS

Wooden, with trucks of less than 60,000 lb. capacity.....	45.00
Wooden, with trucks of 60,000 lb. and over.....	108.00
Wooden, with trucks of 60,000 lb. capacity and over, equipped with metal draft arms extending beyond body bolster, continuous metal draft arms, transom draft gear, metal center sills, or steel underframe	180.00
All steel, or steel superstructure frame with steel underframe.....	270.00

FLAT CARS

Wooden, with trucks of less than 60,000 lb. capacity.....	45.00
Wooden, with trucks of 60,000 lb. capacity and over.....	72.00
Wooden, with trucks of 60,000 lb. capacity and over, equipped with metal draft arms extending beyond body bolster, continuous metal draft arms, transom draft gear, metal center sills, or steel underframe	180.00

In view of the fact that the Rules of Interchange as revised at the annual meeting of the Section held at Atlantic City, June 9 to 16, 1920, will be issued in such a short time, no additional supplements will be issued to the 1499 Code.

Welding Society Decides to Form New York Section

The American Welding Society called a special meeting of its New York members on October 14, at the Engineering Societies building, for the purpose of forming a Metropolitan section of the society. About forty members were present at the meeting, which was presided over by Comfort A. Adams, past president of the society. Temporary officers were chosen and a nominating committee was appointed for the purpose of choosing permanent officers for the local section at its first regular meeting, held on October 25, at 4 p. m., in the same building. Sections of the society have already been formed in Philadelphia, Chicago, Cleveland and Pittsburgh. The New York section began its career with 125 members who have been transferred from the parent association to the local section.

MEETINGS AND CONVENTIONS

Master Boiler Makers' Association.—The thirteenth annual convention of the Master Boiler Makers' Association will be held at the Planters' Hotel, St. Louis, Mo., May 23 to 26, 1921, inclusive.

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.**—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILROAD ASSOCIATION, SECTION III—MECHANICAL.**—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- SECTION III.—EQUIPMENT PAINTING DIVISION.**—V. R. Hawthorne, Chicago.
- AMERICAN RAILROAD ASSOCIATION, SECTION VI.—PURCHASES AND STORES.**—J. P. Murphy, N. Y. C., Collinwood, Ohio.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.**—C. B. Baker, Terminal Railroad, St. Louis, Mo.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.**—R. D. Fletcher, 1145 E. Marquette Road, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.**—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.**—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN SOCIETY FOR STEEL TREATING.**—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.**—Joseph A. Andreucetti, C. & N. W., Room 411 C. & N. W. Station, Chicago.
- CANADIAN RAILWAY CLUB.**—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting November 9. Paper on How to Heat Railway Buildings Economically will be presented by R. H. Black, Engineer Power Plant Construction, Grand Trunk Railway System, Montreal.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.**—Aaron Kline, 626 N. Pine Ave., Chicago. Meeting second Monday in month, except June, July and August, Hotel Morrison, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.**—Thomas B. Koeneke, secretary Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.**—H. D. Vought, 95 Liberty St., New York. Next meeting November 11, Hotel Iroquois, Buffalo, N. Y. Paper on Engine House Organization will be presented by E. R. Webb, M. M., M. C. R. R., St. Thomas, Ont. Annual dinner in the evening.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.**—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill.
- CINCINNATI RAILWAY CLUB.**—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Next meeting November 9. Annual banquet and election of officers. Musical entertainment, speeches by members, etc.
- DIXIE AIR BRAKE CLUB.**—E. F. O'Connor, 10 West Grace St., Richmond, Va. Next meeting November 8-9, Atkin Hotel, Knoxville, Tenn. Paper on Hand Brakes and Why They Should Be Maintained will be presented by M. S. Belk, General Air Brake Instructor, Southern Railway. There will also be a discussion on shop kinks; Recommended Practice as to Air Brakes as adopted by the A. R. A. and the Air Brake Association.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.**—W. J. Mayer, Michigan Central, Detroit, Mich.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.**—J. G. Crawford, 702 East 51st St., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.**—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
- MASTER BOILERMAKERS' ASSOCIATION.**—Harry D. Vought, 95 Liberty St., New York. Convention May 23 to 26, 1921, inclusive, Planters' Hotel, St. Louis, Mo.
- NEW ENGLAND RAILROAD CLUB.**—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting November 11. Paper on The Locomotive Terminal as an Operating Factor will be presented by L. G. Plant, Associate Editor, *Railway Mechanical Engineer*.
- NEW YORK RAILROAD CLUB.**—H. D. Vought, 95 Liberty St., New York. Next meeting November 19. Paper on Loss and Damage to Freight will be discussed.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.**—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Meetings third Wednesday in month, Statler Hotel, Buffalo, N. Y.
- PACIFIC RAILWAY CLUB.**—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings second Thursday in month, alternately in San Francisco and Oakland.
- RAILWAY CLUB OF PITTSBURGH.**—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Friday in month except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.**—B. W. Frauenthal, Union Station, St. Louis, Mo. Next meeting November 12. Paper on the Manufacture of Steel by the Cambria Steel Company will be presented. Motion pictures.
- TRAVELING ENGINEERS' ASSOCIATION.**—W. O. Thompson, N. Y. C. R. R., Buffalo, N. Y.
- WESTERN RAILWAY CLUB.**—Bruce V. Crandall, Chicago. Next meeting November 15.

PERSONAL MENTION

GENERAL

C. E. BROOKS, superintendent motive power of the Grand Trunk Pacific, with headquarters at Winnipeg, Man., has been appointed mechanical assistant of the locomotive department of the Canadian National and the Grand Trunk Pacific, with headquarters at Toronto, Ont. Mr. Brooks will assist S. J. Hungerford, vice-president, in mechanical matters and attend to other duties as assigned. G. E. Smart, general master car builder at Toronto, has been appointed mechanical assistant in the car department to assist Mr. Hungerford in mechanical matters also.

J. J. CONNORS, who has been appointed superintendent of motive power of the Denver & Salt Lake, with headquarters at Denver, Col., was born at Milwaukee, Wis., in 1860, and entered railroad service in 1875 in the shops of the Chicago, Milwaukee & St. Paul, at Milwaukee. During the next 43 years he served continuously with the St. Paul, being promoted successively to foreman, general foreman, master mechanic and assistant superintendent motive power. In 1918 Mr. Connors became general superintendent of the Morrison Foundry Company, the position he held at the time of his recent appointment.

ROBERT D. HAWKINS, who has been appointed general superintendent of motive power of the Atlantic Coast Line with headquarters at Wilmington, N. C., as noted in last month's issue,

R. D. Hawkins

was born on May 22, 1873, at La Fayette, Ind. He graduated from the School of Mechanical Engineering at Purdue University in 1893. He began railroad work in August, 1899, with the Great Northern as chief draftsman. Afterwards he became mechanical engineer, then general master mechanic and later assistant superintendent of motive power. He was promoted to superintendent of motive power on March 10, 1910, and retained that position until October 20, 1917, when he entered military service and was commissioned lieutenant-

colonel, being assigned to Russia with the Railway Engineers. While in Russia he was given command of the Mechanical Section of Railway Engineers under the command of Colonel Emerson. He returned to the United States on January 5, 1920, and was appointed an assistant to the president of the Great Northern, doing special work in connection with mechanical matters. He held that position until his recent appointment.

CHARLES JAMES, mechanical superintendent of the Hornell region of the Erie with headquarters at Hornell, N. Y., has been transferred to the Ohio region with headquarters at Youngstown, O., succeeding A. G. Trumbull, resigned. F. H. MURRAY, shop superintendent at Susquehanna, Pa., has been appointed to succeed Mr. James and J. Topp, general foreman at Susquehanna, has been appointed Mr. Murray's successor.

M. SHEFFER, road foreman of engines on the Chicago, Great Western, with headquarters at St. Paul, Minn., has been appointed trainmaster of the Northern division, with the same headquarters, succeeding G. J. CONGDEN, who has resigned. A. K. ROWE succeeds Mr Sheffer.

CHARLES WHEELER, whose appointment as supervisor of fuel and locomotive performance of the New York Central, with headquarters at Buffalo, N. Y., was announced in the *Railway*

Mechanical Engineer for August, was born on September 6, 1881, at Clyde, N. Y. He attended the Clyde High School and entered the service of the New York Central on April 1, 1901, as a fire cleaner. On September 1, 1901, he was promoted to engine watchman and in October, 1902, became a locomotive fireman. In February, 1907, he was promoted to locomotive engineman; in April, 1909, was appointed division air-brake inspector; and in May, 1918, road foreman of engines. He held this latter position until July 16, 1920, when he was appointed to his present position.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

T. M. ALLISON has been appointed road foreman of engines on the Northern Pacific, with headquarters at Pasco, Wash., succeeding C. A. Wirth, whose promotion to master mechanic, with headquarters at Pasco, was announced in the September issue.

C. L. EMERSON, division master mechanic of the Chicago, Milwaukee & St. Paul, with headquarters at Perry, Ia., has been transferred to the Chicago terminal, with headquarters at Chicago. Mr. Hopper will succeed at the Chicago terminal F. Hopper who has resigned.

R. C. HEMPSTEAD, division master mechanic of the Chicago, Milwaukee & St. Paul, with headquarters at Madison, Wis., has been transferred to the Kansas City division, with headquarters at Ottumwa, Iowa, succeeding C. W. Taylor, who has been assigned to other duties. W. C. Kenney succeeds Mr. Hempstead at Madison.

T. S. LOWE has been appointed assistant master mechanic of the Canadian National Railways at Montreal, succeeding John M. Kerr, transferred.

E. H. McCANN has been appointed master mechanic of the eastern division of the Chicago Great Western, with headquarters at Stockton, Ill.

JAMES SIMPSON, whose promotion to general master mechanic of the Northern Pacific lines, west of Paradise, Mont., with headquarters at Tacoma, Wash., was announced in the September issue, was born at Shrewsbury, England, on September 26, 1859. He entered railroad service in 1879 as a machinist apprentice in the shops of the Michigan Central at Jackson, Mich. From March, 1883, when he became a machinist at Brainerd, Minn., Mr. Simpson has been continuously in the service of the Northern Pacific. In 1885, he was transferred to Mandan, N. D., where he was employed as machinist until 1890, when he was promoted to night foreman, with headquarters at Jamestown, N. D. Three years later he was appointed machine shop foreman at Mandan and he was later transferred to Fargo, N. D. In 1897 he was promoted to general foreman at Mandan and afterwards was transferred to Staples, Minn. In June, 1907, he was promoted to master mechanic with headquarters at Dilworth, Minn. He was transferred to Livingston, Mont., in 1912, and in October, 1918, was appointed master mechanic of the Idaho division, with headquarters at Spokane, Wash., the position he held at the time of his recent promotion.

SHOP AND ENGINEHOUSE

A. B. CLARK, master mechanic on the Southern division of the Chicago Great Western, with headquarters at Des Moines, Iowa, has been promoted to superintendent of shops, with headquarters at Oelwein, Iowa, succeeding M. H. Oakes. H. Brinkman succeeds Mr. Clark.

G. LAMBERG, whose appointment as shop superintendent of the Chicago, Milwaukee & St. Paul at Minneapolis, Minn., was announced in the September issue, was born on May 18, 1874, in Sweden. He attended the high school at Waukesha, Wis., and entered the employ of the Atchison, Topeka & Santa Fe on February 1, 1891, as a machinist apprentice. From 1896 to 1897, he worked as a machinist for the Chicago Great Western at St. Paul, Minn., when he was promoted to gang foreman. In 1899 he entered the employ of the Great Northern at St. Paul as a machinist. In 1903 he was promoted to roundhouse foreman at Larimore, N. D., and in 1904 became gang foreman at St. Paul. In 1908 he was promoted to shop superintendent at Havor, Mont. In February, 1909, he entered the service of the Chicago, Mil-

waukee & St. Paul as a machinist at Minneapolis. In 1910 he was appointed assistant roundhouse foreman; in 1912, gang foreman; in 1914, machine shop foreman, and in 1918, general foreman. On September 1, 1919, he became division master mechanic of the Aberdeen division at Aberdeen, S. D., which position he held until his recent appointment.

JOHN TODD, shop superintendent of the Erie at Susquehanna, Pa., was born on December 18, 1886, at Glasgow, Scotland. He graduated from the high school at Cornell, N. Y., and, in December, 1908, entered the service of the Erie as a machinist. On September 30, 1909, he became machine foreman at Galion, O., and on November 1, 1911, was transferred to Marion, O. On November 1, 1912, he was transferred back to Galion as machine and erecting foreman. On October 1, 1916, he was promoted to general night foreman at Port Jervis, N. Y., and on February 1, 1917, he became general foreman at Marion, O. On June 1, 1919, he was transferred to Susquehanna, Pa., where he held the position of general foreman until his recent appointment as shop superintendent.

PURCHASING AND STOREKEEPING

U. K. HALL, general storekeeper of the Union Pacific, with headquarters at Omaha, Neb., has been appointed general supervisor of stores of the Union Pacific System, with the same headquarters. This is a newly created position having to do with the development of policies, the organization and plans to be followed, in a general way, by the stores organization of the Union Pacific System. The actual details of the plans to be followed out will be executed by the general storekeepers of the units comprising the system so that the general supervisor of stores will act only in an executive and directing capacity, reporting directly to the assistant to the president. Mr. Hall's entire career has been with the lines comprising the Union Pacific System, with the exception of eighteen months spent in Washington as associate manager of the Stores Section of the Railroad Administration. Mr. Hall was born in 1878 at Portland, Ore., and entered the employ of the Union Pacific System in 1897 as an office boy in the office of the purchasing agent. In 1899 he was transferred to the stores on construction work and in 1900 to the accounting department, occupying various positions on roadway, engineering and stores accounts. In 1904 he returned to the stores department and in 1912 was promoted to the position of general storekeeper of the Oregon-Washington Railroad and Navigation Company at Portland. In 1916 he was transferred to Omaha as general storekeeper of the Union Pacific. He will be succeeded in this position by O. Nelson, traveling storekeeper with headquarters at Omaha.

WILLIAM W. MORRIS, who has been appointed purchasing agent of the Northwestern region of the Pennsylvania System, with headquarters at Chicago, succeeding I. B. Thomas, was born in Philadelphia, Pa., on October 3, 1879, and entered railroad service as a clerk in the general offices of the New York, Philadelphia & Norfolk, at Philadelphia, on November 1, 1896. In 1898 he became clerk to the secretary of the Norfolk & Portsmouth Belt Line, in addition to his duties in the office of the president of the New York, Philadelphia & Norfolk. Four years later he was made chief clerk in the purchasing department of the New York, Philadelphia & Norfolk, and at the same time became chief clerk to the auditor of the Norfolk & Portsmouth Belt Line. In January, 1909, when the New York, Philadelphia & Norfolk was taken over by the Pennsylvania, he was transferred to the purchasing department of the latter road, with headquarters at Philadelphia, where he remained until February, 1918, when he accompanied Samuel Porcher, purchasing agent of the Pennsylvania Railroad, to Washington. During his service with the Railroad Administration, Mr. Morris was made secretary to the Central Advisory Purchasing Committee, and later, when that committee was abolished, became assistant to the Director of Purchases. When the roads were returned to private control, on March 1, 1920, he returned to the Pennsylvania as assistant to the general purchasing agent, with headquarters at Philadelphia, the position he held at the time of his recent promotion.

E. V. REINHOLD, assistant to the manager of purchases and stores of the New York Central Lines, with headquarters at Buffalo, N. Y., has been appointed assistant purchasing agent, in charge of fuel, of the New York Central Railroad, with headquarters at New York.

SUPPLY TRADE NOTES

Horace B. Hench, vice-president of Templeton, Kenly & Co., Ltd., Chicago, has resigned.

The Easton Car & Construction Company, Easton, Pa., has opened a branch office in the Railway Exchange building, Chicago.

F. Rodger Imhoff, field engineer at Detroit, Mich., for the Precision & Thread Grinder Manufacturing Company, Philadelphia, Pa., has been appointed sales manager.

A. E. Harrold has been appointed manager of railway sales of the Willard Storage Battery Company, with headquarters at Cleveland, Ohio. Mr. Harrold was born on February 19,

A. E. Harrold

1883, and is a graduate of the electrical engineering course of the Pennsylvania State College. From 1907 to 1908 he served as assistant instructor at the Massachusetts Institute of Technology, and then for three years as director of the testing section of the National Lamp Works of the General Electric Company. From 1911 to 1914 he was electrical engineer of the Wood & Spencer Engineering Company, Cleveland, and since 1914 has been employed by the Willard Storage Battery Company as manager

of its stationary battery department.

Fred J. Passino, assistant district manager of the New York territory of the Independent Pneumatic Tool Company, Chicago, has been appointed district manager at Pittsburgh, Pa.

Clarence C. Brinley has joined the Conveyors Corporation of America as eastern manager of the trolley carrier department and will be attached to the New York office, 110 West 40th street.

Arthur F. Wallace, for many years prior to the war, manager of the Economic Machine Company, Worcester, Mass., has been appointed sales manager of the Metal Saw & Machine Company, Inc., Springfield, Mass.

The American Car & Foundry Company, Madison, Ill., has awarded a contract to the Wimmer Construction Company, St. Louis, Mo., for a new one-story spring works building, to cost approximately \$50,000.

R. G. Berrington, formerly with the Cleveland Twist Drill Company, is now Cleveland sales manager for the Reed-Prentice Company, the Becker Milling Machine Company and the Whitcomb-Blaisdell Machine Tool Company.

Carl J. Schmidlapp and Allan A. Ryan have been elected members of the board of the Chicago Pneumatic Tool Company, New York. Mr. Schmidlapp takes the place of A. F. Cassidy and Mr. Ryan fills a vacancy that had existed in the board for some time.

M. A. Kretchmar, chief lubricating engineer of the Sinclair Refining Company, Chicago, has become associated with the Horrocks Company, Herkimer, N. Y., as supervising engineer in charge of equipment and sales promotion work. The Horrocks Company manufactures the Danight lubricator.

The Keith Railway Equipment Company, Chicago, is completing a new steel freight car shop at Hammond, Ind., which involves an expenditure of \$300,000. The extension will give

to the company complete facilities for building and repairing both steel and wooden freight cars, and tank cars.

E. Payson Blanchard, a mechanical engineer, for several years advertising manager of the Boston Fressed Steel Company, Worcester, Mass., has resigned to go with the Bullard Machine Tool Company, Bridgeport, Conn., where he will take a shop course before entering the sales and advertising departments.

F. F. Fitzpatrick, president of the Railway Steel-Spring Company, New York, has received the decoration of Officer of the Crown of Italy. This order was founded in 1868 by King Victor Emmanuel II and is given as a reward for signal merit to military officers and others who have performed distinguished service in Italy.

The Lancaster Steel Products Corporation, Lancaster, Pa., recently opened a New York office in the National Association building, 25 West Forty-third street. The office is in charge of L. E. Vesey, as district sales manager. Mr. Vesey, for the past year and a half, has been in the Chicago office of this company.

The Norton Company, Worcester, Mass., has opened a branch office for its grinding machine division in room 304 Fenway building, 241 North Pennsylvania avenue, Indianapolis, Ind., under the direction of Walter F. Rogers, district representative. The establishment of this branch office will in no way affect the distribution of Norton grinding wheels. These will be handled as in the past by the Vonnegut Hardware Company.

A. L. Whipple has been appointed representative of the Locomotive Stoker Company, Pittsburgh, Pa., with offices at 50 Church street, New York. In 1888 Mr. Whipple entered

A. L. Whipple

the service of the Fitchburg Railroad, of which he was later assistant to the purchasing agent. He subsequently served as assistant superintendent of the Hoosac Tunnel & Wilmington Railroad, from which position he entered the railway supply field as representative of the Boston Woven Hose & Rubber Company, and then went to the Curtain Supply Company, Chicago, as general sales agent. In 1907, he was sales manager for Forsyth Brothers Company, Chicago, and in 1913, vice-president of the Standard Heat-

ing & Ventilating Company. Mr. Whipple served as entertainment committee chairman of the Master Mechanics' and Master Car Builders' conventions in 1904 and 1905, and vice-president of the Railway Supply Manufacturers' Association in 1908. Before becoming connected with the Locomotive Stoker Company he was vice-president and acting general manager of the Railway Improvement Company, New York City.

The Skinner Chuck Company, Inc., New Britain, Conn., has recently adopted a new trade mark. It shows an alligator in the form of the letter "S," superimposed on a solid black circular background, with the words "Skinner Chucks" around the outside. The alligator was chosen as the symbolic figure best suited to the exploitation of Skinner Chucks, because the alligator is famous for its wonderfully strong jaws and long life.

The Safety Car Heating & Lighting Company and the Pintsch Compressing Company have removed their sales service, treasury and engineering departments from 2 Rector street, New York, and the purchasing, accounting and manufacturing departments from Jersey City, N. J., to their new plant at the corner of Dixwell and Putnam avenues, New Haven, Conn. The executive offices and sales office for the northeastern district will be located at 2 Rector street, New York, as heretofore.

R. A. Bull, vice-president of the Duquesne Steel Foundry Company and former president of the American Foundrymen's Association, has resigned to become consulting metallurgist for the Electric Steel Company, Chicago; Fort Pitt Steel Castings Company, McKeesport, Pa.; Isaac G. Johnson Company, Spuyten Duyvel, N. Y.; Lebanon Steel Foundry Company, Lebanon, Pa.; Michigan Steel Castings Company, Milwaukee, Wis.; and the Sivyer Steel Castings Company, Milwaukee, Wis.

The St. Louis Pump & Equipment Company, engineers and manufacturers, has been organized, with headquarters at St. Louis, Mo., to manufacture and install liquid handling equipment, specializing in units for gasoline and oil, measuring devices, etc., especially adapted to railroad and industrial use. The company has opened executive offices in the International Life building and temporary factory space has been secured in the western industrial section of St. Louis. C. C. Fredericks, of Ft. Wayne, Ind., has been elected general manager, and John C. Roberts, Jr., is president. Others affiliated with the company are: Willard D. Smith, Sherwood Hines and J. S. Farrell.

C. H. Jackman has been appointed sales agent of the Pressed Steel Car Company and Western Steel Car & Foundry Company, western district, with headquarters at Chicago. Mr. Jackman was born at Crystal Lake, Ill., on May 5, 1893, and was educated at the University of Illinois, graduating in 1916. He entered the employ of the American Bridge Company at Gary, Ind., as a draftsman in the master mechanic's department. Later he was with Joseph T. Ryerson & Son, Chicago, as estimator and sales correspondent until December 10, 1917, when he enlisted in the Air Service, U. S. A. After completing the army's course for pilots, he was commissioned Second Lieutenant, R. M. A. Upon receiving his discharge from the service, he returned to Joseph T. Ryerson & Son as special steel salesman, where he remained until his recent appointment as sales agent of the Pressed Steel Car Company and the Western Steel Car & Foundry Company.

American Car & Foundry Company

W. H. Sanford, for many years district manager of the Buffalo, N. Y., plants of the American Car & Foundry Company, New York, has been appointed assistant vice-president in charge of sales in the Buffalo district. This is in connection with the company's plan of extension in that district.

Prior to the formation of the American Car & Foundry Company, Mr. Sanford was employed by the Union Car Company, and when that company was absorbed he was appointed paymaster and cashier at the Depew plant. In 1902 he was appointed local auditor of the Buffalo district, followed by promotion to the position of resident representative. In 1912 he was made district manager in charge of the Depew and Buffalo plants.

Mr. Sanford has been succeeded as district manager by Andrew H. Gairns, who was district manager of the company in Chicago. He will direct the operation of the new plant in Buffalo, also the foundries located there and the plant at Depew. Mr. Gairns has had an extended experience in steel car work and locomotive building and is well qualified to take up the duties demanded by the Buffalo district.

The company's new plant now under construction in Buffalo will be used for building all-steel cars, with a capacity for turning out 20 to 30 cars a day. It will be equipped with the most modern machinery and labor-saving devices known, and there will be a number of features introduced which are entirely new and novel to the car building industry. In addition to the new car-building plant, a modern up-to-date office building will be erected on property recently acquired across Babcock street. The grey iron foundry at the Buffalo plant has been completely re-equipped and is now engaged in quantity production. The Niagara wheel department has also been brought up to a high state of efficiency.

At Depew, during the recent war, the company was the largest producer of 155 mm. shells. Immediately following the armistice, the entire Depew plant was reconstructed and is now capable of building 20 cars a day. E. G. Englehart is assistant district manager at Depew in charge of operations at that place, reporting to Mr. Gairns.

The car company's plans, as outlined above, involve a total expenditure of \$3,500,000. With the developments that have taken place, the car company becomes one of the largest manufacturing operations in Buffalo and vicinity.

TRADE PUBLICATIONS

TEMPERATURE CONTROLLERS.—A small illustrated folder has been issued by the Foxboro Company, Inc., Foxboro, Mass., describing in detail their automatic temperature controllers.

STEEL LOCKERS AND SHELVING.—The Van Dorn Iron Works Company, Cleveland, Ohio, has issued a pamphlet illustrating and describing the Van Dorn steel lockers and Van Dorn Simplex shelving.

THE OXYGRAPH.—The Davis-Bournonville Company, Jersey City, N. J., has issued a new bulletin showing some details of their No. 1-A and No. 2 mechanically operated cutting torches for cutting steel up to 20 in. thick.

LINK BELT SILENT CHAIN DRIVES FOR CEMENT MILL EQUIPMENT.—The Link-Belt Company, Chicago, has ready for distribution a 32-page book, No. 345, which gives and substantiates reasons why the Link-Belt drive is ideal for operating ball mills, tube mills, conveyors, etc.

PRICE LIST.—Catalogue B-20 issued by the Armstrong Bros. Tool Company, Chicago, Ill., embodies and makes effective many changes in the list prices of the company's products. Attention is also called to the following additions to their line: Spring Threading Tool, Knurling Tool (3 new sizes), Bent Tail Heavy Duty Lathe Dogs, Aero Tappet Wrenches and Ford Wrench Sets.

BELT LACING.—Under the title "Short Cuts to Power Transmission" the Flexible Steel Lacing Company, Chicago, has published a practical manual of belting practices. After discussing the factors to be considered in buying belts and describing the more important types in general use, the booklet covers the care of belts and the application of lacing. Valuable information concerning belt speeds, power transmitted, and the cause of belt trouble is given.

BALANCED DRAFT.—"Modern Practice in Combustion Control" is the title of a booklet which has been issued by the Engineer Company, New York. This booklet contains 28 pages of interesting and instructive data of particular value to those interested in combustion. The science of combustion is treated at some length and consideration is given to some of the elements of combustion control. The principles of balanced draft and its many advantages are explained at length. A description of the apparatus and operation of balanced draft is given.

WATER SOFTENERS.—"Reap As The Harvester" is the title of a booklet published by the Graver Corporation, East Chicago, Ind., which describes the installation of Graver water softeners at the plant of the Wisconsin Steel Company and the savings effected by their use. In the second part of the book, the construction and operation of the Graver hot-process water softener is described. An interesting feature of the book is the series of artistic drawings of ore docks, blast furnaces and other equipment used in the manufacture of iron and steel.

NONPAREIL INSULATING BRICK.—A 72-page illustrated book on the insulation of high temperature industrial equipment, such as boilers, furnaces, stills, hot blast stoves, ovens, kilns, etc., has been issued by the Armstrong Cork Company, Pittsburgh, Pa. The results of a study, from both theoretical and practical standpoints, on the subject of heat insulation compiled in this book make it a valuable and instructive treatise. It is conveniently divided into sections, each section dealing with a particular type of industrial apparatus.

MACHINERY QUARTERLY.—The first issue of the Machinery Quarterly by Joseph T. Ryerson & Son, Chicago, is now ready for distribution. This book is not intended as a complete machinery catalog, but does contain descriptive matter covering the line of equipment manufactured or sold by the Ryerson company. One or more machines or tools of each of the various classes are shown accompanied with brief descriptions and specifications. If the size or type of machine particularly desired is not shown, an illustrated bulletin with complete description and specifications will be forwarded on request.

ELECTRIC Crucible Tool Steels—Uniform and Dependable.

Write for your copy of our new book on Ludlum Steel.

This is the plant in which have been developed and perfected Seminole, the unbreakable chisel steel; Mohawk Extra, the high-speed steel that cuts big, red-hot chips; Silcrome, the steel that will not corrode when heated; non-shrinking, ball-bearing, and permanent magnet steels; etc.

Ludlum steels have an unexcelled quality of absolutely controlled analysis.

Ludlum is the steel that reduces costs.

As a means of conserving paper during the war, only a limited number of copies of the index for the *Railway Mechanical Engineer* were published and these were distributed to subscribers upon request. This arrangement was apparently satisfactory to our readers and, as the paper shortage still exists, the same practice will be followed this year. Subscribers who wish to obtain a copy of the index should write to the Circulation Department of the *Railway Mechanical Engineer* so that the request will be received before January 1, 1921.

The Index for 1920

While the locomotive terminal is distinctly an operating factor and terminal management is truly an operation function, it is the mechanical equipment of the terminal that determines its capacity not only to maintain locomotives in good condition but to expedite their movement. There is a surprising variety of design in all terminal construction. It would be hard to find two ash pits alike on a single railroad and while there is still a preponderance of old inclined coal trestles in operation, modern coaling stations exhibit an infinite variety of design. Very few railroads have any well defined standards relating to enginehouse construction and equipment and these show such a wide divergence in character and completeness that it would be well to ask whether mechanical engineers could not profitably devote more time to a study of the various locomotive terminal facilities, not only on their own but on neighboring railroads, to determine what types are most effective and economical in operation. There is little question but that locomotive terminal facilities will undergo greater relative development in the next ten years than any other mechanical facility and it is important that mechanical engineers should

be prepared to advise the railroads wisely in regard to the design and equipment of these facilities. It is a mistake to entrust the design of a new terminal wholly to the engineering department. It should be borne in mind that these facilities are to be used continuously by the mechanical department, and every terminal project should represent the best judgment of both mechanical and civil engineers. Moreover, in view of the true function of a locomotive terminal, the transportation department might well be consulted in regard to terminal improvements. What every railroad should do is to outline a broad, comprehensive plan that will take into consideration terminal needs for years to come. A committee representing the mechanical, engineering and transportation departments should be selected to study the problem and outline a plan to which all future construction should adhere.

There is one activity of the government that should be better understood and more fully appreciated, particularly by mechanical engineers. This is the United States Patent office. Often regarded as an institution for protecting certain individual interests, it is in reality the greatest single factor in the mechanical development of the age. The railroads are particularly indebted to our patent laws for the rapid development of the many specialties that have made modern railroading possible. George Westinghouse would not have devoted so important a part of his career to the development of the air brake if he had not been assured of a proprietary interest in this invention by virtue of the patent law, nor could a mechanical engineer today afford to spend any considerable time or money in the development of an invention if he were not certain that his title to this invention would be clearly established. Very few industries could afford to devote years in perfecting a certain device if the improved device could

later be marketed or used by anyone without the payment of a royalty. The telephone, the electric light and practically every other mechanical achievement owe their development in part to our system of patent protection. It is not too much to say that our industrial development is entirely dependent upon the patent office. Any mechanical engineer who has recently been in touch with the United States Patent office knows that this branch of the government is presented with more work than it can handle expeditiously and that as the salaries of its technical experts have been maintained at a pre-war standard its work is handicapped by the loss of many good men who have been attracted to outside positions. It may require months to obtain decisive action on an important invention because the particular division to which the application is assigned has hundreds of applications ahead of it waiting to be acted upon. It is not generally known, however, that the fees attached to these applications considerably exceed the running expenses of the patent office and that a surplus is annually turned over to the Secretary of the Interior to be applied against the deficit incurred by some other department of the government. Not only the railroads and the industries that supply the railroads, but every mechanical engineer should individually feel concerned over the welfare of the patent office and should exert whatever influence he can bring to bear towards putting this important governmental activity upon the most efficient basis.

So far from arriving at any definite conclusions concerning the relative merits of steam and electric traction, the recent

**"The Monarch
of the
Rails"**

discussion at a joint meeting of the Electrical and Mechanical Engineering Societies had the effect of confusing many of those who came to the meeting with fairly definite notions as to the characteristics of both modes of traction. Out of the host of generalities and maze of details presented at this meeting and abstracted elsewhere in this issue, a few really important conclusions as to the relative merits of steam and electric locomotives may be garnered. If one will disregard the comparisons attempted between modern electric locomotives and out-of-date steam locomotives or between electric locomotives operating under hypothetical conditions and imaginary steam locomotives operating under assumed conditions, he may find in parts of the discussion a statement of facts that shed real light on the ability of the electric locomotive to save coal. A representative of the N. Y. N. H. & H. stated that the coal consumption on the electrified section of that railroad over an extended period had averaged 9.3 lb. per car miles in passenger service and 84 lb. per 1,000 ton-miles in freight service. Even if Mr. Ralston had not stated that the coal consumption on steam locomotives over the same section of the line averaged 19.3 lb. per car-mile and 199 lb. per 1,000 ton-miles it would be evident to anyone familiar with steam locomotive practice that electric locomotives are actually hauling both freight and passenger trains in main line service with very much less coal than would be possible with the most modern steam locomotive operation. If representatives of the electrical manufacturers would confine their arguments to a simple statement of the actual coal consumption over an extended period upon the basis of ton and car-miles hauled, or where water power is utilized to convert this into an equivalent coal consumption they would have less difficulty in proving their contention that the electric locomotive can save coal. When it comes to a question of maintenance, the advantage of the electric locomotive is not quite so clear and the exponents of electrification are prone to overlook power plant maintenance as a factor to be reckoned with in connection with the electric locomotive. Broadly speaking, the electric locomotive is not "the monarch of the rails" as it has been described, but always

a servant at the beck and call of the central power station whereas the steam locomotive is truly a self-contained unit and will always occupy a field by virtue of this fact that can never be invaded by its electrical rival. For an unbiased exposition of clear thinking on the entire subject we commend our readers to that part of the discussion contributed by W. L. Bean and A. W. Gibbs.

The so-called fusion welding processes have received a remarkably rapid development and extension in the com-

**Fusion Welding
An Art
By Itself**

paratively few years since their introduction as regular features of railway equipment maintenance. As a natural consequence of this rapid development a reaction has become evident in the minds of some of those who have to do with the results as applied to locomotive and car parts. This is not necessarily serious but it is a warning that the future extension of the art must be based on a far more thorough study of the conditions to be met by the welds, of welding methods and practices, and of the metallurgical aspects of welding, than has been devoted to the subject in the past. Fusion welding has passed through its pioneer development and must now be reduced to a science.

The greatest obstacles in the way of stabilization and sound future extension of these welding processes in the railroad shops are the provisions of the so-called National Agreement, which makes them mere adjuncts of the other crafts. Under this agreement welding must be performed by machinists, boiler makers, blacksmiths, tinsmiths and carmen, and by its provision, the qualifications which control in the selection of welders is seniority of employment as a craftsman in one of the other trades. Under these conditions it is manifestly impossible to maintain the degree of permanency in the welding forces essential to the development of highly skilled and experienced operators; the kind of work assignable to each welder limits his experience and outlook and the supervision is divided among the regular shop foremen, to none of whom welding is a primary interest.

The short time in which one may acquire a sufficient degree of skill in the manipulation of the torch or electrode so that he may "get by" is possibly one of the most potent factors in the rapidity with which the processes have come into general use. But it also constitutes one of the greatest dangers to sound future development. One of the best ways of avoiding this danger is to organize fusion welding work as a trade by itself, for training in which men may be selected who have the proper temperament and whose purpose is to make welding a permanent vocation. Not only will this lead to the development of more skilled operators, who in time will supplement their skill with more or less knowledge of the metallurgical questions involved, but better supervision will become possible because of the concentration of the work in a department by itself and because the craft training of the welders will provide the material from which competent supervisors may be selected. The possibilities for economy in the railroad shop offered by these processes are too great to permit the strangling of their future development by the permanent establishment of conditions under which they must now be applied.

One of the most important factors in insuring good tool service is a suitable complement of heat treating furnaces, so

**Don't Neglect
Your
Pyrometers**

equipped that close regulation and accurate measurement of temperature is possible. One of the essential items of a tool treating installation is the pyrometer. Without this instrument the color method of judging temperatures must be depended upon and it has been demonstrated that the most skilled heat

treater is unable, under all conditions, to determine temperatures within limits of variation narrow enough to be permissible if uniform results are to be obtained. These facts have already been recognized by mechanical department officers of many railroads and where the conviction has been backed up by the installation of the equipment, gratifying results have generally been obtained. But in some cases there has been a tendency to assume that, once provided, such equipment needs no further attention. Where such an attitude exists the results are very likely to prove disappointing.

The pyrometer is a delicate instrument and care is required in its installation and its readings should be checked frequently if accuracy is to be insured. Otherwise the effect

of its use may be even worse than if full dependence had been placed on the eye of the tool treater. Where the best results have been obtained it will generally be found that some means has been provided for periodically checking and calibrating the pyrometers. Some pyrometer manufacturers advocate the checking of these instruments at intervals not exceeding three months, not necessarily because the instruments are expected to require adjustment at such frequent intervals but as an insurance against the loss which might follow should an instrument for any reason get seriously out of adjustment. The periodical checking of these instruments offers no great difficulty and there are available at least three means from which to choose. Under most conditions probably the most satisfactory plan is to purchase a standard instrument which should be used only for comparisons with the service instruments and for special investigations in the test department. These instruments may be calibrated, say once a year, by sending them to the Bureau of Standards at Washington or to a commercial testing laboratory. Or, where the commercial testing laboratory is readily accessible it may be entirely practicable to send the service instruments themselves for periodical calibration. The pyrometer manufacturers in some cases are developing service organizations for the purpose of checking instruments of their own make without removing them from the shops where they are in use, a regular service which may be obtained for a nominal fee.

Whatever means may prove most practicable, it is important that the periodical calibration of pyrometers be provided for and insisted on if the maximum return on the investment is to be obtained from modern heat treating equipment.

Much has been said about the need for improvement in car conditions and everyone having to do with the maintenance of rolling stock is endeavoring to reduce the percentage of bad order cars. Unfortunately, however, the number of cars reported in bad order is a very poor measure of car conditions and their effect on operating costs. Only too frequently a campaign to reduce the percentage of bad order cars, instead of actually improving conditions, leads to a lowering of maintenance standards which has an adverse effect on the cost of operation. Many cars of weak construction are still in service and must be perpetuated for several years until enough

**Poor Equipment
and
Operating Costs**

new equipment can be financed and built to make up for the accumulated shortage of the war period. In laying out programs of re-enforcement there is a tendency to consider only the investment value of the equipment and many of the older cars are being permitted to remain in service until they are automatically retired by being broken up in service. Failures of such equipment cause innumerable delays to train movement with a heavy quota of crew overtime which must be paid for at time and one-half time. Their use leads to the destruction of freight, which must be paid for by the railroads, and adds a serious element of danger to train operation. The buckling of a car of weak construction in a heavy freight train, is almost sure to result in scattering equipment and freight alike all over the right of way. Such accidents are common and when their cost is added to the cost of overtime from train delays at terminals and on the road, caused by the necessity of switching out defective equipment, a field for economy will be found which justifies the extension of betterment programs well beyond the point fixed by considerations of capital expenditure, theoretical earning capacity and maintenance costs.

What Do You Think?

The editors of the Railway Mechanical Engineer aim to present in each issue a sufficient variety of material to insure that every subscriber will find a number of articles that are of direct interest and value to him. Is the range of subjects covered in this issue great enough to give you the information that you are looking for? Let us look it over and see.

One of the principal articles describes a series of tests of the locomotive booster. No device that has been brought out in recent years has created as much interest as this. Here is the story of what it does in actual service.

A prominent electrical engineer has recently proposed the electrification of all the railroads north of Washington, D. C., and east of the Allegheny mountains. When such proposals are being made, railroad men will surely want to have a clear idea of what the change to electric operation could be expected to accomplish. The papers on the Relative Merits of Steam and Electric Traction will help in forming an opinion on this important subject.

The locomotive terminal is becoming more important as locomotives grow larger and more difficult to maintain. The article on the Locomotive Terminal as an Operating Factor was written with this thought in mind and is intended to give constructive suggestions for getting more service from the motive power.

The principal feature in the Car Department section is the report of the C. I. C. I. & C. F. A. convention. The papers and discussions show what the car men who are actually on the firing line are thinking and doing. Whether you are interested in yard or shop work, passenger or freight this will give you some new ideas.

Don't you suppose that your welders would do better work if their jobs were tested occasionally? The author of the article on testing welds is a practical man and a vise and a hammer are the only tools needed to make the tests he recommends.

Every shop and roundhouse man knows how much trouble is caused by cut flanges. The new method of curing this old trouble which was developed on the New York Central at West Albany is described in this issue.

These are only a few of the high spots; the rest of the articles are just as helpful in their special fields.

When New Year's Day arrives the editors will all resolve to make the Railway Mechanical Engineer better than ever next year. When you finish reading this issue we would like to have you sit down and write the editors telling them what you liked and what you did not like in the recent issues, and what they can do in the coming year to make, not their paper but YOUR paper, more interesting and valuable.

THE PRICE OF GOVERNMENT OWNERSHIP.—Disclosures in the United States Shipping Board investigation furnish convincing grounds for argument against government ownership and operation. While the investigation has not yet proceeded far enough to determine whether any blame for unnecessary expenditures rests with those in charge of the Board's affairs, enough has been revealed to show that governmental ownership and operation is a prohibitively costly luxury.—*Virginian Pilot and Norfolk Landmark*.

NEW BOOKS

Proceedings of the American Railway Tool Foremen's Association for 1919, 274 pages including advertising, 6 in. by 9 in., bound in cloth. Published by the Association, R. D. Fletcher, secretary-treasurer, 1145 East Marquette road, Chicago.

This book contains a complete transcript of the proceedings of the 1919 convention of the American Railway Tool Foremen's Association. This convention was the first to be held since 1916 and, despite unfavorable conditions existing at the time it was held, a number of very instructive papers were presented and thoroughly discussed. The value of the year book, however, does not lie wholly in its presentation of the proceedings of the convention, as it contains a number of well illustrated papers on jigs and special devices and tools which were received too late to be presented before the association during the convention. Many of these devices contain valuable suggestions for shop foremen other than tool foremen.

Data Book for Engineers. Published by the Locomotive Superheater Company, 30 Church street, New York. 79 pages, 4½ in. by 8 in., bound in flexible leather covers.

The most noticeable feature of this book is the ease and facility with which any required data or tables may be referred to. The book contains the data most frequently desired by steam or power plant operators with special reference to those in charge of superheated steam boilers. The first few pages of the book summarize the factors affecting the advisability of installing superheater units in saturated steam boilers. Fuel cost, engine performance, boiler maintenance, labor charges, steam-line losses and the relative first cost are among the factors considered. Tables showing the factors of evaporation, grate area per horsepower and the dimensions of various types of boilers are given; also additional tables showing the size of chimneys per boiler horse power, fan dimensions and dimensions of standard boiler tubes. Much additional instruction in the way of determining the flow of steam in pipes, calculating boiler horse power, speed of pulleys, etc., is given. For reference in solving problems, saturated and superheated steam tables are shown in the back of the book. All tables and information are conveniently arranged and can be readily located by means of a carefully arranged index.

Proceedings of the Master Boiler Makers' Association. Edited by Harry D. Vought, secretary of the association, 95 Liberty street, New York. 149 pages, 6 in. by 9 in., bound in cloth.

This book contains the official proceedings of the twelfth annual convention of the Master Boiler Makers' Association held at Hotel Curtis, Minneapolis, Minn., on May 25 to 28, inclusive, 1920. As customary, the first few pages of the book contain a list of officers for the year 1920-1921, subjects and committees for the 1921 convention, and a list of the members and guests who registered at the convention. The opening exercises and addresses are reported in full, together with reports of the secretary, Harry D. Vought, and treasurer, W. H. Laughridge. Committee reports, together with the complete discussions, are given in the book, including the report of the Committee on the Best Type of Wash-out Plug and four other important topics, as previously announced for consideration at the 1920 convention. In addition, there is included the address of Professor Alfred S. Kinsey, of Stevens Institute of Technology, and a paper on Electric Welding by Charles L. Hempel. The report of the Committee on Law and Resolutions is given and the latter part of the book is devoted to publication of the constitution and by-laws, together with the membership list and a list of the Women's Auxiliary.

Bituminous Coal Storage Practice. By H. H. Stoek, C. W. Hippard and W. D. Langtry. Bulletin No. 116, Engineering Experiment Station, University of Illinois, Urbana, Ill., 150 pages, 6 in. by 9 in., bound in paper.

The growing inability to maintain a steady flow of coal from the mine to the consumer to take care of the fuel demands of the country currently, especially during the winter season, has attracted wide interest to the problem of storing large quantities of coal near the point of consumption. One of the most serious handicaps to the storage of bituminous coal is the constant danger of spontaneous combustion. A study of the causes of spontaneous combustion and methods of prevention has been undertaken by the Engineering Experiment Station of the University of Illinois and has been in progress for several years. Considerable information on the subject was included in Circular No. 6, on "Storage of Bituminous Coal," issued in 1918, and Bulletin No. 116, contains much additional information which has been obtained by a study of the circumstances surrounding a considerable number of fires in stored coal, as well as of methods of inspecting storage piles which have been followed with success in the prevention of fires. The results of these studies are given in detail and the bulletin is invaluable to any large user of coal who now has storage piles or contemplates the storage of coal in quantity.

The Making, Shaping and Treating of Steel, by J. M. Camp and C. B. Francis, Bureau of Instruction, Carnegie Steel Co. 600 pages, illustrated, 5 in. by 8 in. Bound in cloth. Published by J. M. Camp, Carnegie building, Pittsburgh, Pa.

The scope included by the title of this work naturally suggests a voluminous treatise. However, the authors have covered the comprehensive subject very well in a book of 600 pages by eliminating all non-essential matter. The book is frankly a description of the steel industry as it exists; it is not written from the viewpoint of the steel expert and comparatively little is said about the future development of the industry. For that reason, anyone thoroughly versed in the manufacture of steel might find little that is new in the book. For the railroad officer who desires a thorough knowledge of the steel industry and its most important products, the book is extremely valuable. Designed as a course of instruction for salesmen, this work necessarily includes practically all the information required by those who buy or use steel.

The book is strictly non-technical and opens with a discussion of the fundamentals of physics and chemistry as applied to steel making. The entire process from the ore to the finished product is then outlined in a systematic manner. The various ores, refractories, fuels, fluxes and slags are discussed and the manufacture of coke by the beehive and by-product processes is described. In the discussion of the making of pig iron, the construction and operation of the blast furnace and the chemistry of the process are covered. The Bessemer and open-hearth processes are treated in a similar manner, a short history of their development being included. Another chapter is devoted to the manufacture of steel in electric furnaces, which is followed by a description of the duplex and triplex processes. The section on the shaping of steel discusses chemical properties, describes the rolling mill and covers in some detail the rolling of blooms, billets, plates, rails and rail joints, the strip and merchant mill products, rolled steel wheels and axles.

The third part of the work treats of the constitution, heat treatment and composition of steel. The solution theory of steel is explained and the theory and practice of heat treatment are discussed with this as a basis. The concluding chapters are devoted to the effect of the common elements on the mechanical properties of carbon steel and a short description of the more usual types of alloy steel.

New York Central Pacific Type Equipped with Locomotive Booster

TESTS OF A PACIFIC TYPE BOOSTER LOCOMOTIVE*

Additional Tractive Effort of Booster Increases Tonnage Rating for Division on New York Central

“**I**DLE weight and spare steam harnessed in a simple way to do useful work at a critical time.” This, in a few words, describes the locomotive booster which causes the trailing wheels to act as driving wheels in starting the train and to get it over the hard pulls on the road. For the past ten years or more locomotive designers have been striving for increased drawbar pull. Their efforts have increased the load per pair of drivers and the number of driving wheels until today the load limit that track and bridge structures will bear has been closely approached. In starting and

foot of a momentum grade necessitates cutting loose and running for water. Stopping for signal or other cause on a hill may necessitate backing down to get started again. Loss of time in starting disrupts train schedules and often results in loss of train rights with consequent overtime, as well as increased operating costs.

Locomotives as ordinarily built today are hauling around a large percentage of weight that is useless except to permit of making the boiler larger. To permit train loading that would utilize a greater percentage of the available draw-

Fig. 1—Profile of West Shore Division at Catskill

at slow speeds every locomotive built has greater boiler capacity than it can utilize. While, of course, increased wheel loads and larger units mean greater tractive effort, the limiting factor, the ruling grade, determines the load a locomotive can haul over the division. To obtain maximum practical effectiveness from the locomotive and offset the tonnage limit imposed by the ruling grade several methods are in use. One is to station pushers at the foot of the grades to help the train over the hill; another is to make up the train, wherever possible, so as to drop several cars at some way point. Both are expensive and unsatisfactory.

Loading locomotives to the limit involves several other perplexing operating problems. A water plug located at the

bar pull over the entire division and yet have sufficient power available for the critical points where extra power is needed led to the invention and development of the locomotive booster.

For approximately two years Engine 3149 equipped with the booster has been in operation on the New York Central. To determine the operating advantages of the booster, a series of tests was conducted on the River division between Ravena and Weehawken. This division is 130 miles long with a ruling grade of one per cent at Bogota going west and 0.46 per cent at Haverstraw going east. The locomotive used in these tests, 3149, is of the Pacific type with a load on drivers of 184,000 lb., steam pressure 200 lb. and a tractive effort of 40,000 lb. It was exhibited at the Atlantic City convention and has been in continuous road service since that time; no special preparations were made

*A description of the locomotive booster was published in the *Railway Mechanical Engineer* of May, 1920, page 265.

for the test. A dynamometer car was used to obtain the necessary data.

In making these tests information was wanted on the following items:

1. Practical increase in tonnage that could be hauled over the division because of the booster.
2. Effect of the booster on train operation over the division.
3. Maximum drawbar pull with the booster in action.
4. Maximum drawbar pull without the booster.
5. Time saved over the division because of the booster.
6. Increased train acceleration by use of the booster.
7. Effect of a crew, inexperienced with the booster, operating a locomotive equipped with a booster.

Test Results Going East

The first test was made going east from Ravena to Weehawken. Without the booster, Engine 3149 is rated from Ravena with 2,600 tons and runs to Newburgh where the tonnage is reduced to 2,100 tons, a reduction of 19.2 per cent. In making this test it was decided to endeavor to bring 2,582 tons through to Weehawken. This not only involved getting over the ruling grade at Haverstraw, but also introduced other interesting and important operating problems.

At Catskill the water plug is located at the bottom of two grades. It is the usual practice to leave the train at the top of the grade west of the water plug, run two miles for water, back up to the train and make a run down-grade to get sufficient momentum to carry over the up-grade. The profile of the road at this point (Fig. 1) shows a down-grade of

Fig. 2—Dynamometer Record of Booster Locomotive on Catskill Grade

0.55 per cent and an up-grade averaging 0.375 per cent. Running for water in this way consumes 20 to 30 minutes' time in good weather. When the weather is bad with sleet and snow 30 minutes' time is usually lost in pumping up the train line alone before the train can be started after coupling up, thus more than doubling the time lost.

In the test run the practice referred to was not followed. Engine 3149 hauled the train to the water plug intact, took water and started up the grade with the full train with the booster in operation. As shown by the dynamometer record (Fig. 2) the locomotive, with the booster in operation, accelerated to five miles per hour very quickly, the drawbar pull showing 41,067 lb. at this point and in a distance of

580 ft. the speed increased from 5 to 8½ m.p.h., or an increase of 70 per cent. When the booster was disengaged and the locomotive took the load entirely, the drawbar pull showed 33,497 lb., a difference of 7,570 lb.

Reference to Fig. 1 showing the road profile and Fig. 2

RULING TONNAGE FOR WEST SHORE DIVISION				
Distance				
Weehawken 0 miles	Cornwall 52 miles	Newburgh 57 miles	Kingston 88 miles	Ravena 129 miles
TONNAGE GOING EAST WITHOUT BOOSTER				
.....	2,100 tons	2,600 tons
TONNAGE GOING EAST WITH BOOSTER				
2,582 tons	2,582 tons
TONNAGE GOING WEST WITHOUT BOOSTER				
1,800 tons	2,100 tons	2,600 tons
TONNAGE GOING WEST WITH BOOSTER				
2,015 tons	2,577 tons	2,745 tons

showing the dynamometer record clearly indicate the part the booster played in making possible the starting of the

Fig. 3—Performance of Booster Locomotive With 22.6 Per Cent Excess Tonnage on Haverstraw Grade

train and getting up to speed on the grade; without the booster this performance would have been impossible.

At this point an important time saving operating situation developed. Because of the time saved at Catskill, West Point was reached just three minutes before an express was due. The express was followed to Weehawken, whereas usually two or three local passenger trains are allowed to go ahead. At times this adds another 30 minutes' delay in addition to the time lost at Catskill. After leaving Catskill the booster was used for starting whenever the train was stopped for signals or other reasons, each start showing rapid acceleration.

The ruling grade on this division is known as the Haverstraw grade (Fig. 3). It is over six miles long and the average gradient is about 0.46 per cent. This grade was approached at a speed of 33 m.p.h. with the booster idle and continuing up-grade the speed dropped as follows:

- At the end of the first mile, 28½ m.p.h.
- At the end of the second mile, 19 m.p.h.
- At the end of the third mile, 12 m.p.h.
- At the end of the fourth mile, 8 m.p.h.
- At the fifth mile the speed was 7½ m.p.h. and falling rapidly. The drawbar pull was 36,441 lb. Without the assistance of the booster the train would have stalled.

At this point the booster was cut in on a 0.52 per cent grade, and in 432 ft. the speed reached eight miles per hour and the drawbar pull 42,900 lb., an increase of 6,459 lb. drawbar pull or 17.7 per cent because of the booster. In the first ¾ mile, after the booster was working, the speed reached 10 m.p.h. This shows an acceleration, because of the booster, in three-quarters of a mile of 33⅓ per cent with

a train tonnage 22.9 per cent above normal. In taking this train over the ruling grade the booster was used for about 1 5/8 miles and just before being disengaged a drawbar pull of 45,080 lb. was recorded on the dynamometer car.

The train arrived at Weehawken with the same tonnage with which it started from Ravena. This was the first time this tonnage had ever been hauled over the entire division

Fig. 4—Drawbar Pull and Speed Record Ascending Bogota Grade

by this type of locomotive. In addition no difficulty was experienced and the locomotive was handled by a crew not regularly assigned to the locomotive. Since this test was made the crew regularly operating this locomotive has hauled 2,618 tons over the division, an increase of 24.6 per cent over the regular tonnage.

Test Results Going West

By referring to the tabulated statement it will be noted that the tonnage rating of this locomotive without the booster

Fig. 5—Stalling Test to Determine Maximum Drawbar Pull With the Booster

is 1,800 tons to Newburgh, at which point it is increased to 2,100 tons to Kingston, where it is again increased to 2,600 tons to Ravena. Use of the booster permitted increasing the tonnage to 2,015 out of Weehawken, increasing it to 2,577 at Cornwall and again increasing it to 2,745 tons at Kingston, which tonnage was hauled to Ravena.

The ruling grade going west on this division begins 7 1/4 miles from Weehawken at Bogota. It is a one per cent grade approximately 1 1/4 miles long. The dynamometer record was started at a point eight miles from Hohokus, where the speed was 25 m.p.h., and about two-thirds the way up the speed had dropped to 13 m.p.h. At this point the booster was cut in. As shown in Fig. 4 the drawbar pull immediately

increased from 34,228 lb. to 38,793 lb., an increase of 4,565 lb.

At West Nyack a test was made to determine the combined power of the locomotive and the booster. The grade at this point is 1.04 per cent. The train was brought to a standstill and a start made by taking slack. As shown by the dynamometer car record (Fig. 5) the train proceeded .235 of a mile, where it stalled, and the maximum drawbar pull at zero speed registered 51,138 lb. The boiler pressure re-

Fig. 6—Stalling Test to Determine Maximum Drawbar Pull Without the Booster

mained constant; the throttle was wide open and the reverse lever in the corner.

To determine the maximum drawbar pull of the locomotive without the booster a test was made on an 0.86 per cent grade into Congers, the tonnage at this point being 1,958 tons, one car having been set off on account of hot boxes. With the booster working, the train was brought entirely on the grade, the booster then cut out, and the engine proceeding until

A Close View of the Trailer Truck With the Booster

stalled. As shown by the dynamometer car record (Fig. 6) the drawbar pull registered 40,421 lb. at zero speed. To get the train moving again the booster was engaged and the maximum drawbar pull registered 49,953 lb., showing an increase of 9,532 lb., or the additional drawbar pull which the booster exerted.

At Cornwall the tonnage was increased to 2,577 tons, the

usual tonnage from this point to Newburgh being 1,800 tons. At West Park, on a .52 per cent grade, it was found necessary to use the booster again as the speed had dropped to 12 m.p.h. Upon arrival at Kingston the train was increased to 2,745 tons, which is 145 tons in excess of the regular rating of 2,600 tons, and the train continued to Ravena successfully handling this tonnage.

One of the important features of the booster emphasized by these tests was the rapid acceleration, which is accomplished at practically no increase in weight, as the booster weighs less than 4,000 lb. The following tabulation shows clearly the reason for this:

Maximum drawbar pull of locomotive.....	40,421 lb.
Drawbar pull of locomotive necessary to move train on given grade.....	36,441 lb.
Difference (force available for acceleration).....	3,980 lb.
Maximum drawbar pull of locomotive with booster in operation..	49,618 lb.
Less drawbar pull necessary to move train.....	36,441 lb.
Reserve for acceleration with booster is increased to.....	13,177 lb.
Deducting force available for acceleration without the booster...	3,980 lb.
Increased force available for acceleration on the same locomotive with the booster operating.....	9,197 lb.
Hence 9,197/3,980 equals 231 per cent increase in force available for acceleration purposes.	

On freight trains rapid acceleration is important, as it enables a quick get-away and the increase in available starting power means a smooth, even start.

Driving Mechanism of the Booster

Quick acceleration often saves sufficient time to permit a freight train to continue on its run when otherwise it might necessarily have to take a siding to permit other trains to pass. Moreover, the additional capacity which the booster contributes to the locomotive in starting avoids damage to rolling stock by avoiding the need of taking slack.

On passenger trains it means saving time in starting from station or other stops. A few minutes saved at each stop with a heavy train helps maintain operating schedules. The smooth, easy start also adds to the comfort of the traveling public.

Conclusions

From the results of these tests the following conclusions were drawn:

1. The booster makes possible increasing the tonnage that a locomotive can haul.
2. It provides quick acceleration that helps maintain schedules more easily and reduces the time over the division. In several instances under observation the time consumed in getting freight trains out of terminals and yards was reduced 50 per cent.
3. It eliminates the need for taking slack in starting.
4. It reduces tire and rail wear as slipping of drivers is avoided.
5. Because of its smooth, steady pull at starting it reduces wear and tear on equipment and eliminates breaks-in-two.
6. It increases the average speed over grades and eliminates stalling.
7. The booster power is always instantly available at speeds below 12 m.p.h.
8. It helps relieve traffic congestion, increasing the maximum ton-miles over the division.
9. No extra coal is consumed because of the booster, and fuel economy should result because the time required over the division is reduced.
10. The booster is automatic in operation and control and adds no extra duties to the engine crew.
11. It gives the effective increase in starting drawbar pull that an additional pair of drivers would give, but avoids hauling around 50,000 lb. or more weight that a larger locomotive would involve, weight that is useless a large percentage of the time and that present track and bridge structure will not carry.
12. The booster is in motion less than 10 per cent of the time. Its maintenance is negligible.
13. It avoids stalling where sudden weather changes while enroute would render impossible the hauling of normal tonnage.
14. It provides a reserve capacity that helps to even out the difference between an experienced and inexperienced crew.

New York Harbor, Looking North Along West Street

RELATIVE MERITS OF STEAM AND ELECTRIC TRACTION

Strong Points of Both Outlined at a Joint Meeting of Electrical and Mechanical Engineers

THE advantages of steam and electric locomotives were discussed by their exponents at a joint meeting of the New York Section of the American Institute of Electrical Engineers, the Metropolitan Section of the Railroad Section of the American Society of Mechanical Engineers, held on October 22 in the Engineering Societies building, New York. One paper on steam locomotives and two papers on electric locomotives were presented and the papers were discussed by several railroad and railroad supply men.

The following are abstracts of these papers and the subsequent discussion:

ADVANTAGES OF ELECTRIC LOCOMOTIVES HAVE BEEN GREATLY OVERSTATED

BY JOHN E. MUHLFELD
Railway and Industrial Engineers, Inc.

In the protection and control of railroad net earnings, one of the most important factors is the kind of motive power to be used.

When discussing or recommending the further electrification of the whole or any part of the steam operated railroads in the United States, the most important item involved is a correct and complete statement of facts, comparing the most up-to-date steam with similar electric operations, after which immediately come the important factors of the necessary financing and legislation.

While there is much existing steam road trackage that can and should receive first consideration as regards electrification for the purpose of eliminating gases from underground terminals and tunnels and to give relief to terminal or line traffic congestion in the vicinity of large commercial and industrial centers, it would be financial suicide to electrify immediately adjacent connecting and intermediate mileage, particularly in view of the improvements that can be made in both existing and new steam locomotives in increasing general efficiency and economy in operation and maintenance.

Before the electric locomotive can be made permissible for general application the electrical engineer must reduce first costs; promote interchangeability; provide a motor which will efficiently, economically and flexibly cover a wide range of speeds and not break down or deteriorate from overloading and heating; reduce complication, wear and corrosion in transmission and contact line apparatus; and substantially reduce the current losses between the point of power production and the locomotive drawbar. Likewise the steam railway mechanical engineers, locomotive builders and specialty manufacturers, if they are to continue the steam locomotive in its present field of usefulness, must become more active in modernization and bring about improvements that will substantially increase its capacity and thermal efficiency by the use of higher steam pressures and superheat; compounding; more efficient methods of combustion; utilization of waste exhaust steam and products of combustion heat; better distribution and use of live steam; reduction of dynamic weights; greater percentage of adhesive to total weight and a lower factor of adhesion; and by a substantial reduction in standby losses.

In order to determine the relative advantages of modern steam and electric locomotives the following may be stated as important items for consideration:

Financing. Few if any existing steam roads can justify or stand the additional capital investment required per mile of road for electrification, except for short distances under very

special conditions such as prevailed on the Norfolk & Western; where the ventilation and 1.5 per cent grade of $\frac{5}{8}$ mile single track tunnel restricted the train movements to six miles per hour on a congested traffic section of the main line, and even then only providing the fixed charges and operating expenses are not too excessive.

Adaptability to Existing Trackage and Facilities. Foremost in favor of a continuation of the steam locomotive is its flexibility and adaptability to existing railroad trackage, terminal and operating facilities, and the relatively low first cost per unit of power developed for the movement of traffic. Being a self-contained mobile power plant, it is possible to quickly transfer needed or surplus power from one part of the line to another and to concentrate it when and where necessary, whereas with the electric locomotive this is impossible unless electrification extends over the entire property or the sources of power supply have almost prohibitive peak load capacity. Furthermore, the various systems of electrification do not make the interchanging of electric locomotives practicable without much non-productive first-cost, complication, and maintenance and operating expense.

Effectiveness in Increasing Trackage Capacity. Without a doubt electrification increases the capacity of a terminal. As already set forth, special line conditions may make electrification advisable for short distances, but results do not justify the frequent reference by electrical engineers to the weakness of steam locomotive haulage during the unprecedented cold weather in the winter of 1917-18. If electrification would have obviated the difficulty, why did the New Haven not operate at 100 per cent of its capacity, over its electrified zone at that time? If short of locomotives or motor cars the New York Central had plenty of surplus that was not in use and which could not be utilized outside of its electric zone where it was badly needed. The probable answer is lack of interchangeability, which is still one of the most discouraging operating factors involved in any electrification scheme. Although under the multiple unit system locomotive and train operation it is theoretically possible to provide unlimited sustained hauling capacity, at the head of the train, the tonnage to be handled without rear end or intermediate helpers is limited by the ability of the draft rigging on the cars to withstand the pull and shock, and this limitation can be readily met and exceeded in steam locomotive design and operation.

Train Speeds. The average freight car is in main line movement only about 10 per cent of its life, or 2 hr. and 24 min. out of each 24 hr. Therefore, increasing train speeds beyond established economic limits at the sacrifice of tonnage, and with an increase in fuel, track and equipment upkeep and danger of operation is not the solution of the freight traffic problem.

As the electric locomotive is a constant speed machine, whether going up or down grade, and is unable to utilize its rated capacity and effectiveness through the same range of speed and tractive power variations as the more flexible steam locomotive, the latter can therefore be more efficiently operated over the continually changing up and down grades, levels, curves and tangents traversed by the average freight train in this country. With respect to passenger train service, where speed is more of a factor, the steam locomotive performs equally satisfactorily.

Fuel Consumption. Great economy in fuel consumption and cost is the principal claim for electrification and recently electrical engineers have advanced the theory that it

would be possible to save at least two-thirds of the coal consumed by the existing steam locomotives and that the useful carrying capacity of existing trackage could be increased about 10 per cent by the elimination of company coal movement, if electric locomotives were substituted.

The basis for arriving at these comparative figures is so obviously ridiculous that they warrant comment only for the reason of the general publicity given.

However, accepting the assertion that the proposed electrification will produce 1,000 gross ton-miles for an average of 40 kilowatt hours, or 100 lb. of 12,000 B. t. u. coal, as stated and generally approved by electrical engineers, what can the modern steam locomotive do to justify its existence? The following results of dynamometer car tests made during 1918, may be of interest. The steam locomotives tested were of the ordinary superheated Mikado freight type. One locomotive was fitted for hand firing and burning coal on grates while another was equipped for burning powdered coal in suspension. The tests were made in tonnage freight service on the Santa Fe main line between Ft. Madison, Iowa, and Marceline, Mo. (the profile consisting of .8 per cent ruling grades), a distance of 112.7 miles, during March and April, 1918.

Item	Powdered coal locomotive	Hand fired locomotive
1—Total trips run (112.7 miles each).....	14	10
2—Total miles run.....	1,578	1,127
3—Average running time (hours).....	5.06	5.25
4—Average dead time (hours).....	1.25	1.01
5—Average total time (hours).....	6.31	6.26
6—Average speed (m. p. h.).....	22.3	21.6
7—Average trailing tonnage per train.....	2,278	2,283
8—Average gross 1,000 ton miles.....	256.5	255.4
9—Average coal per gross 1,000 ton miles.....	82.4	114.8
10—Average B.t.u. per pound of coal as fired.....	12,025	11,160

It can be assumed from the foregoing that the average yearly performance will approximate 100 lb. of 12,000 B. t. u. coal per 1,000 gross ton-miles, or equivalent to what we are promised for the expenditure of billions of dollars of new capital and the loss of billions of dollars' worth of investment in existing plant and equipment to inaugurate the comforts of electrification.

It is also not out of order to refer to dynamometer car tests which it is understood have been made on the New York Central, wherein on the basis of the thermal value of the coal, a single expansion superheated steam locomotive required, per drawbar horsepower hour, about 2.6 lb. of coal as compared with about 2.25 lb. for an electric locomotive.

Efficiency of Locomotive Operation. The off-setting fuel and energy losses, due to standby losses in the steam operation, and decrease in efficiency on account of fluctuating loads in the electric operation must not be lost sight of. Neither should those incident to the transforming, transmission and conversion of electric current and like factors be neglected.

It is unquestionably true that when operating under ideal fixed load conditions, the central power station, either hydro-electric or steam, can produce a horsepower with less initial energy input than is possible on a steam locomotive. It is also true that the standby losses on existing steam locomotives are, in ordinary practice, a serious proportion of the total fuel consumption, but it is likewise a fact that the majority of these can be substantially reduced if not entirely overcome, by modernizing the present equipment and improving maintenance and operation which would then rob the electrical engineers of their main argument in favor of a blanket electrification.

While the electrical engineers and manufacturers in this country deserve great credit for the progress made in the development of the electric locomotive, they have as yet been unable to design one which can operate at maximum efficiency throughout its range of load. The point of maximum efficiency being well established and fixed, and the current curve on an electric motor not being flat, any over or underload from the predetermined maximum efficiency load in-

creased the current consumption. Furthermore, when, on account of transportation conditions, a motor is required to carry an overload for periods of five or six hours, it either breaks down due to heating or otherwise requires special power consuming auxiliaries or long rest periods for the dissipation of the heat stored within itself due to the resistance of the current through the wiring, to permit of continuous operation.

The number of factors entering into an analysis of the net thermal efficiency of the electric locomotive, in terms of drawbar pull, are so many as to make it impossible, with the lack of dynamometer car and laboratory test data, to arrive at a figure which is not based on a number of assumptions; but as a matter of interest, assuming, that *all of the factors are affected equally* in the electric locomotive, the net thermal efficiency at the drawbar, when taking into consideration the boiler, engine, generator, step-up transformer, a. c. transmission, step-down transformer, a.c.-d.c. converter, d.c. transmission, motors, and machine efficiencies may, as representative of average existing practice, be taken as shown in Table 1.

TABLE 1—COMPARATIVE EFFICIENCIES OF ELECTRIC AND STEAM LOCOMOTIVES

Equipment	ELECTRIC EQUIPMENT			
	Efficiency factors and net thermal efficiency, per cent.	Load rating, per cent		
		100	75	50
Boiler	Factor
	Efficiency	76.7	76	72
Engine	Factor	18.25	18.29	19.17
	Efficiency	14	13.9	13.8
Generator	Factor	90	89.5	86
	Efficiency	12.6	12.44	11.88
Transformer, Step-Up	Factor	98	96	90
	Efficiency	12.34	11.93	10.67
Transmission, A.C.	Factor	90	95	97
	Efficiency	11.10	11.32	10.34
Transformer, Step-Down	Factor	98	96	90
	Efficiency	10.87	10.85	9.30
Converter, A.C. to D.C.	Factor	80	75	63
	Efficiency	8.69	8.13	3.85
Distribution, D.C.	Factor	90	95	97
	Efficiency	7.82	7.71	5.66
Motors, D.C.	Factor	91.5	90.8	89.5
	Efficiency	7.15	7.00	5.05
Machine Efficiency	Factor	81	85	90
	Efficiency	5.79	5.95	4.54

Equipment	Superheated or saturated	STEAM LOCOMOTIVE			
		Efficiency factors and net thermal efficiency, per cent.	Load rating per cent		
		100	75	50	
Boiler	Superheated	Factor	
		Efficiency	42.7	54.9	65.9
Cylinders	Superheated	Factor	
		Efficiency	11.9	11.0	10.5
Machine	Superheated	Factor	5.08	6.04	6.92
		Efficiency	7.8	8.4	7.8
Boiler	Saturated	Factor	3.51	4.82	5.46
		Efficiency	7.5	8.0	8.5
Cylinders	Saturated	Factor	3.85	4.83	5.88
		Efficiency	7.7	8.0	8.2
Machine	Saturated	Factor	2.70	3.86	4.47
		Efficiency

Comparing the electric and steam locomotive figures as illustrated, the relative percentage of power delivered at the track rails to 100 per cent B. t. u. in the coal would be:

Kind of locomotive	Net thermal efficiency at load ratings of		
	100 per cent	75 per cent	50 per cent
Electric	5.79	5.95	4.54
Steam, superheated	3.85	4.83	5.88
Steam, saturated	2.70	3.86	4.47

As 100 per cent load rating conditions would, in practice, occur only momentarily and as the majority of the drawbar load represents from 30 to 60 per cent of the locomotive maximum drawbar capacity, comparison should properly be made only of the net thermal efficiencies at 50 per cent load ratings.

Various dynamometer car and laboratory test performances of representative types of steam passenger and freight locomotives confirm the foregoing figures relating to steam operation. At speeds of from 15 to 75 miles per hour the existing superheated steam locomotive thermal efficiency actually ranges from 5.3 to 8.1 per cent as compared with the calculated figures of from 4.83 and 5.88 per cent for 75 and 50

per cent load ratings, respectively. Adding to this an increase of from 15 to 50 per cent in net thermal efficiency that may be produced from developments now under way, the steam locomotive of the future will be quite a respectable assembly of engineering efficiency.

Cost of Maintenance. In determining the maintenance cost of the electric locomotive the popular error is to take into account the locomotive proper, whereas a true comparison can only be made by including all corresponding elements as found in the self-contained steam locomotive which goes back to the upkeep of all facilities having to do with the utilization of the fuel or water power, including the central power station buildings; boilers; engines; conversion, transmission, distributing and contact line systems; sub-stations; track rail bonding and insulation; electric disturbance cut-outs or neutralizers; extra expense in upkeep of the electric zone trackage; and like auxiliaries and finally the electric locomotive itself.

Peak Load Conditions in Relation to Traffic Requirements. With the steam locomotive the traffic requirements are met by the distribution and utilization of the necessary number of self-contained motive power units as required, regardless as to the capacity of one or more central power stations or of any limitation in quantity, or in price, of the total available power output. The operation of one or of 500 steam locomotives at their maximum capacity at any given moment, or for any duration of time on a single division, is of no concern.

However, in order to meet the ideal conditions for electrification, the traffic should be uniformly spread or scattered over the 24 hr. period, whereas in the majority of cases train movement is based on traveling and shipping conditions and cannot be advanced or delayed in order to eliminate peak load conditions.

Rate of Acceleration. In order that the desired running speeds can be reached in the minimum of time after the starting of trains, the ability of a locomotive to accelerate its load rapidly is of considerable importance and in this respect the electric power has had the advantage. The steam locomotive engineer has, however, not lost sight of this fact and improvements already made in boiler and cylinder horsepower ratios, as well as developments now undergoing for the utilization of existing non-productive adhesive weight and to increase the coefficient of friction between the propelling wheels and the track rails, will enable the steam locomotive to duplicate the performance of its electric competitor in this regard.

Train Braking. Since the development of regenerative braking with the electric locomotive, great emphasis has been laid on the increased security of operation over heavy grade lines due to the ability of the locomotive to hold the train under complete and positive control on the down grade without brakes, by temporarily converting the main motors into generators to produce electricity which is returned to the line for use by some other locomotive in pulling a train. Considerable attention has also been directed to the saving brought about through the elimination of the ordinary air braking on such down grades.

While the regenerative system of braking can no doubt be developed to the point where it can be safely used, in view of the recent serious accident on the St. Paul, due to the failure of the regenerative brake control, just what economy will result is problematical. When the power so generated cannot be directly used by another pulling locomotive on the line, it must be otherwise absorbed, and it remains for the electrical engineers to prove just how much of it is lost in conversion or by absorption and the resulting net gain as compared with the investment, fixed charge and upkeep and operating cost for the equipment involved.

Effect of Weather Condition. Even though the full

steaming capacity, horsepower and drawbar pull of a modern steam locomotive can be developed during cold weather conditions, there are the factors of radiation and freezing to be reckoned with, which give the electric locomotive the advantage in winter, particularly, as its effectiveness is greater on account of the lesser tendency for the motors to overheat. This winter advantage, however, is largely overbalanced during the summer when the main motors heat, especially under overloads, and require cooling at terminals or otherwise overheat and result in insulation break-downs or burnouts, or other troubles.

Road Delays and Tie-Up. While the electric locomotive has the advantage of not being required to take on fuel and water, except for the operation of steam heating equipment for passenger trains, with the increased capacity of the modern steam locomotive tenders, and the lower water and fuel rates per drawbar horsepower developed, the delays due to taking on these supplies have been greatly reduced and need not be serious.

Barring collisions, wrecks and like accidents not due to the system of motive power in use, steam operation is not susceptible to complete tie-ups as is the case with electrification, where short circuits or failures occur due to rains, floods, storms and like causes, and as the result of motor, wiring and insulation heating, deterioration and break-downs, as the individual mobility of each piece of motive power without regard to any outside source of power enables quick relief.

Terminal Delays. The examination of reports of a dense heavy freight traffic railroad in the Eastern District shows the time of its steam locomotives for a recent two months' period distributed as follows:

1—In road service.....	50 per cent of total time
2—At terminals waiting trains and otherwise in hands of Transportation Department....	26.4 per cent of total time
3—At terminals in hands of Mechanical Department	23.6 per cent of total time

There is no doubt that the electric locomotive has an advantage over the steam locomotive as regards time required for periodical boiler work, cleaning and rebuilding fires, fueling and watering except where fuel oil is used, but where terminal delays occur due to waiting for trains, such as the foregoing statement set forth, the time required for such work does not become an expensive determining factor in the daily average miles to be obtained per locomotive.

Hazards. With the establishing of more scientific and careful methods of designing, testing and inspection, and the more extended use of safety appliances, the failures of steam locomotive boilers and machinery, particularly those resulting in personal injury, are relatively low as compared with the work performed. It is, therefore, doubtful if there is any greater proportion of risk from the steam locomotive in that regard than from electrocution and other attendant dangers from high voltage electrification.

FOURTEEN POINTS FOR ELECTRIFICATION

BY A. H. ARMSTRONG

Chairman, Electrification Committee, General Electric Company

A comparison of the modern steam and electric locomotive leads immediately to a discussion of the relative fitness of the two types of motive power to meet service conditions. Place at the disposal of an experienced train despatcher a locomotive capable of hauling any train weight that modern or improved draft gear can stand, at any speed permitted by track alignment regardless of ruling grade or climatic conditions, that can be run continuously for a thousand miles with no attention but that of the several operating crews, and witness what he can accomplish in his all-important task of expediting freight movement. It is not merely a question of replacing a Mikado or Mallet by an electric locomotive of equal capacity. The economies thus effected are in many instances not sufficient

in themselves to justify a material increase in capital account. The paramount need of our railways today is improved service and this can be brought about by introducing the more powerful, flexible and efficient electric locomotive. While a maximum standing load of 60,000 lbs. per axle has been generally accepted for steam engines, it is well known that an impact of at least 30 per cent in excess of this figure is delivered to rail and bridges due to unbalanced forces at speed. Impact tests taken on electric locomotives of proper design disclose the feasibility of adopting a materially higher limiting weight per axle than 60,000 lb., without exceeding the destructive effect on track and road bed now experienced with steam engines.

Accepting the Mikado and Mallet as the highest developments of steam road and helper engines for freight service, the following general comparison is drawn with an electric locomotive that it is entirely practicable to build without in any respect going beyond the experience embodied in locomotives now operating successfully.

COMPARISON ON STEAM AND ELECTRIC LOCOMOTIVES

Type	Mikado	Mallet	Electric
Weight per driving axle	2-8-2 60,000 lb.	2-8-8-2 60,000 lb.	6-8-8-6 60,000 lb.
Number driving axles	4	8	12
Total weight on drivers	240,000 lb.	480,000 lb.	720,000 lb.
Total weight loco. and tender	480,000 lb.	800,000 lb.	780,000 lb.
Trac. eff. at 18 per cent coef.	43,200 lb.	86,400 lb.	129,600 lb.
Gross tons 2 per cent grade	940	1,880	2,820
Trailing tons 2 per cent grade	693	1,495	2,430
Speed on 2 per cent grade	14 m.p.h.	9 m.p.h.	16 m.p.h.
H.P. at driver rims	1,620	2,080	5,570
I. H. P. at 80 per cent eff.	2,030	2,600
Trailing ton miles per hour on 2 per cent gradient	9,700	13,500	38,800

In view of the facts, it is a modest claim to make, therefore, that the daily tonnage capacity of single track mountain grade divisions will be increased fully 50 per cent over possible steam engine performance by the adoption of the electric locomotive.

Aside from the power returned by means of regenerative braking (14 per cent of the total on the Chicago, Milwaukee and St. Paul Railway) the chief advantage of electric braking lies in its assurance of greater safety and higher speeds permitted on down grades. The heat now wasted in raising brake shoes and wheel rims often to a red heat is returned to the trolley system and becomes an asset instead of a likely cause of derailment.

Cost of Maintenance

Probably in no one respect does the electric locomotive show greater advantage over the steam engine than in cost of maintenance. Electric locomotives are now being operated 3,000 miles between inspections on at least two electrified railways and the following figures are available.

ELECTRIC LOCOMOTIVE MAINTENANCE, YEAR 1919

	N. Y. C.	C. M. & St. P.	B. A. & P.
Number locomotives owned	73	45	28
Locomotive weight, tons	118	290	84
Annual mileage	1,946,879	2,321,148	566,977
Repairs per mile	6.39 cents	14.65 cents	6.48 cents

In contrast, it can be stated that the present cost of maintaining a type 2-8-8-2 Mallet is fully 60 cents per engine mile, without including many miscellaneous charges not shared by the electric locomotive.

Possibly more direct comparison may be better drawn by expressing maintenance in terms of driver weight.

STEAM AND ELECTRIC REPAIRS

	Steam Mallet	C. M. & St. P. Electric
Cost repairs per mile	60 cents	14.65 cents
Weight on drivers	240 tons	225 tons
Cost, repairs per 100 tons loco. wt. on drivers	25 cents	6.52 cents

Including all engine service charges, the facts available give foundation for the claim that electric locomotives of the largest type can be maintained for 25 to 30 per cent of the upkeep cost of steam engines operating in similar service.

Fuel Saving

Fuel economy figured prominently among the several reasons leading up to the replacement of the steam engine on the Chicago, Milwaukee and St. Paul Railway as brought out by a careful analysis of the performance of the steam engines then in service.

The data indicated on the curves illustrated is therefore submitted as applying to a particular equipment only. No claim is made that it is representative of the best modern

Coal Record on a Basis of 1000 Gross Tons Moved for Steam and Electric Runs from Harlowton to Three Forks, Mont.

steam engine performance, although many thousands of steam engines still in operation will show no greater economies than those given in the following table:

C. M. & St. P. TESTS—LOCOMOTIVE DATA

Type	Steam	Electric
Weight of engine	2-6-2 206,000 lb.	4-4-4-4-4 568,000 lb.
Weight of tender	154,000 lb.
Weight total engine and tender	360,000 lb.	568,000 lb.
Weight on drivers	152,000 lb.	450,000 lb.
Ratio driver weight to total	42.2 per cent	79.3 per cent
Rigid wheel base	13 ft.	10 ft. 6 in.
Diameter drivers	63 in.	52 in.
Cylinders	21 in. x 28 in.
Boiler pressure	200 lb.
Heating surface	2,346 sq. ft.
Grate area	45 sq. ft.
Water capacity	8,000 gals
Coal capacity	14 tons

The run of 111.1 miles from Harlowton, elevation 4,162 ft., to Three Forks, elevation 4,066 ft., over the Belt Mountain Divide at Loweth, elevation 5,789 ft., was made by steam with 871 ton trailing in 26 cars and by electric locomotive hauling 64 cars weighing 2,762 tons. The fuel furnishing power to the steam train was coal having the following analysis:

COAL ANALYSIS

Fixed carbon	Volatile carbon	Ash	Moisture	B.t.u's
47.99	38.98	8.35	4.68	11,793

Electric power was furnished by water and hence no direct coal equivalent is provided by the test result. To afford a common basis of comparison, however, a single assumption seems permissible and a rate of 2½ lb. of coal per kilowatt hour is taken as representative of fair electric power station practice. Coal burned under the steam engine boiler was determined by weighing at the end of the run and by detailed record of scoops en route. Power input to the electric locomotive was obtained by carefully calibrated recording watt meters as well as curve drawing volt and ampere meters.

Pounds coal per gross 1,000 ton miles may vary on steam locomotives from 650 to 50.5 according to gradient and with no standby losses whatever included. The boiler must be kept hot at all times, however, and fully 33 per cent can

safely be added to include the inevitable standby losses inherent to steam engine operation. Except over very long runs with terminals at the same elevation it seems hardly possible therefore to accurately compare engine performance over different profiles by such a variable unit as pounds coal per 1,000 ton mile.

However efficient the power plant on wheels may reasonably be developed without too seriously interfering with the sole purpose of the steam engine, the hauling of trains, it can never approach the fuel economies of modern turbine generating stations. Whatever transmission and conversion losses are interposed between power house and electric locomotive are more than compensated for by the improvement in the load factor resulting from averaging the very fluctuating demands of many individual locomotives.

THEORETICAL COMPARISON MODERN STEAM AND ELECTRICAL LOCOMOTIVES
HARLOWTON-THREE FORKS

Type	Mikado	Electric
Wt. on drivers	240,000 lb.	450,000 lb.
Wt. engine and tender	480,000 lb.	568,000 lb.
Trac. eff., 18 per cent coef.	43,200 lb.	81,000 lb.
Trailing ton, 1 per cent grade	1,420	2,836
Hp. hr. at driver rims	4,360	8,200
Coal per ind. hp. hr.	3	
Coal per driver hp. hr.	3.75	
Standby loss—test result	9,042 lb.	
Standby loss per hp. hr.	2.15 lb.	
Total coal per driver hp. hr.	5.90 lb.	
Coal at power house, kw. hr.		2.5 lb.
Coal at power house, hp. hr.		1.86 lb.
Coal at loco. driver, hp. hr.		3.09 lb.
Coal credit due regeneration		.55 lb.
Net coal at driver hp. hr.	5.90 lb.	2.54 lb.
Total net coal	24,800 lb.	20,900 lb.
1,000 trailing ton miles	157,500	314,000
Coal per 1,000 ton miles	158 lb.	66.7 lb.
Ratio coal burned	2.37	1

The above table is based upon actual electric locomotive performance, Harlowton-Three Forks, coal taken at 2½ lb. per kilowatt hour at assumed steam power station. Steam engine values are based upon the known working efficiency of a Mikado equipped with superheaters but penalized with the same standby losses actually determined by test. A test run from Harlowton to Three Forks with a modern Mikado engine hauling 1,420 tons may possibly show a lower average fuel rate than 3 lb. per I. H. P. Hr. at drivers, less standby waste than 9,042 lb. coal, but the average annual performance of many such engines would be most excellent if it reached the net figure arrived at of 5.9 lb. coal per actual H. P. Hr. work performed at drivers. The electric run, however, is being duplicated daily, as to relation between Kw. Hrs. and ton miles and it is just this reliability of electric operation that may at times give rise to misunderstanding in the comparison of steam and electric data.

Comparative Cost

Comparing the cost of equivalent steam and electric motive power, it is apparent that on the basis of the same unit prices for labor and material, the first cost is approximately the same. While electric locomotives cost possibly 50 per cent more than steam for equal driver weight, the smaller number required to haul equal tonnage may quite offset this handicap, especially with quantity production of electric locomotives of standard design.

The steam engine also demands a formidable array of facilities peculiar to itself. This expense covers fuel and water stations, shops and engine houses, shop machinery, turn tables, ash pits, etc. The task of proving the electric case is not made easier by the fact that steam engine facilities are already installed and may have little or no salvage value to offset new capital charge for electrification.

Summary

Some of the principal advantages claimed for the electric as compared to the steam locomotive may be briefly stated as follows:

1—No structural limits restricting tractive effort and

speed of electric locomotive than can be handled by one operator.

2—Practical elimination of ruling grades by reason of the enormously powerful electric locomotives available.

3—Reduction of down grade dangers by using regenerative electric braking.

4—Very large reduction in cost of locomotive maintenance.

5—Very large saving of fuel, estimated as two-thirds the total now burned on steam engines in operation.

6—Conservation of our natural resources by utilizing water power where available.

7—Material reduction in engine and train crew expense by reason of higher speeds and greater hauling capacity.

8—Increased valuation of terminal real estate following electrification.

9—Increased reliability of operation.

10—Material reduction in operating expense due to elimination of steam engine tenders and most of the company coal movement, the two together expressed in ton miles approximately nearly 20 per cent of present gross revenue ton mileage.

11—Large reduction in effect of climatic conditions upon train operation.

12—Postponement of immediate necessity for constructing additional tracks on congested divisions.

13—Attractive return on cost of electrification by reason of direct and indirect operating savings effected.

14—Far reaching improvements in operation that may revolutionize present methods of steam railroading.

ELECTRIC MOTIVE POWER FOR TRAFFIC DEMANDS OF TOMORROW

BY F. H. SHEPARD

Director of Heavy Traction, Westinghouse Electric & Manufacturing Co.

With the present standards of train make-up, classification and terminal handling, electrification will double the capacity of any railroad. With the better equipment we can expect in the future, together with the evolution of improved methods of operation contingent on electric power, this capacity should be doubled again, thus securing four times the present capacity. This should certainly be accepted as a vision of the future, and why not our aim? Unless some broad and consistent program is embraced, the situation, which is serious indeed today, may well be calamitous tomorrow. The electric locomotive has generally, thus far, been a mere substitute for the steam locomotive, although, in some cases, due to the greater power of the electric locomotives, there has been a modification of the handling of traffic.

Two conspicuous cases of this have been the Norfolk & Western and the Chicago, Milwaukee & St. Paul. In the case of the Norfolk & Western, two electrics handle the same train as was formerly handled by three Mallet engines, but at twice the speed. In this operation, owing to the great increase in hours of road service as well, one electric locomotive is the practical equivalent of four of the Mallet engines replaced.

On the Chicago, Milwaukee & St. Paul, the notable change has been the elimination of intermediate terminals on the electrified section between Harlowton, Montana, and Avery, Idaho, 440 miles long. There is at present a single intermediate engine terminal, but the latest passenger locomotives are detached from trains at this terminal for inspection and work only, which takes place about once in each eight or ten trips. On regular schedule, these engines make a run of 440 miles each day, being taken off for inspection at Deer Lodge after mileage varying from three to five thousand miles. On occasion, when, due to a schedule derangement, engines have been maintained in continuous road service for periods of thirty hours or more, for a full day of twenty-four hours,

mileage records of up to 766 miles in this mountain service have been established. These records are truly indicative of what may be expected with electric power.

With the retirement of the lighter and weaker car equipments, a material increase in the weight of trains will be realized. Without the limitation in train speed commonly accepted as a handicap to operation of tonnage trains, who can say what the limit to train load will be with electric power? In fact, the character of railroad operation which may be secured with electric power has not yet been visualized. Every other industry that has been electrified has experienced a revolution in methods and service due to electrification. This should be equally true in the case of the movement of our railroad traffic.

Car inspection now takes place at the terminus of each engine district. If, under condition of electric operation, the engine district can be increased to 200, 400 or even 500 miles, is there any good reason why car inspection should not be eliminated at the present intermediate terminals? In fact, is not the general standard of maintenance of equipment of doubtful value on the present basis of inspection at each 100 mile interval? Cars in subway service, which is certainly full of potential hazard, are economically and reliably maintained through inspection at intervals of one or three thousand miles. The elimination of these intermediate terminals, with the resultant necessity of keeping the train moving on the main line, would secure an enormous increase in miles per car with a corresponding saving in equipment.

The generation of power in central stations is surrounded with many refinements, and in the consumption of coal, there is every opportunity for skillful handling and supervision, so that the thermal efficiency of a modern central station is relatively high and is also continuously maintained. With the steam locomotive, on the other hand, the thermal efficiency is dependent not alone upon the design of the locomotive, but the manner in which it is worked, its condition, which differs widely from the best, and finally by the skill in firing. The electric locomotive, on the other hand, consumes power only when in service, and works at any load at its designed efficiency. The average performance, in the case of the electric locomotive approximates the maximum in efficiency, while the steam locomotive, on average performance, will differ widely therefrom.

We can therefore expect that with the best steam locomotives the average coal consumption will be equal to twice the coal rate for the same work performed by electric locomotives with steam generated power. Obviously, with hydro-electric generation, the saving in fuel is complete. There is further economy due to the lesser work performed, because the electric locomotive does not have to trail supplies of fuel and water, nor is there need for the hauling of coal to points of local supply, which will always be greater than hauling to electric central stations.

There are a considerable number of different designs of electric locomotives all in successful operation, and each possessing certain advantageous features. Further experience will, undoubtedly, result in the survival of common types for the different classes of service. The great latitude with which electric locomotives can be designed, while fundamentally most desirable, is in itself at the present time somewhat of a handicap. This is now the subject of intensive analysis and this study is undoubtedly developing, as well, a better knowledge of the running characteristics of the steam locomotive.

To state the case briefly, we are all interested in the transportation problem. Electrification is bound to be the most potent factor for its relief. We should therefore invite and embrace closest co-operation with the engineering and mechanical skill which has been so productive in the steam locomotive field.

Discussion

The discussion of the principal papers took the form of reading prepared discussions some of which are outlined as follows:

H. B. Oatley, chief engineer, Locomotive Superheater Company, stated that while both electric and steam locomotives were undoubtedly able to stand on their own merits, that it was futile to discuss these merits without some idea of what the return on the capital investment will be, in view of the difficulties encountered by the railroads in obtaining capital. Modern electric locomotives must be compared with modern steam locomotives, the stand-by fuel losses of steam locomotives should be compared with similar losses in the power plant, losses inherent to the transmission and transformation of electric power.

F. J. Cole, chief consulting engineer, American Locomotive Company, stated that in the 27 years since the building of the first electric locomotive for operation of the tunnel into Baltimore, only about one per cent of the steam locomotives in this country have been superseded by electrics. Advocates of electric traction fail to produce complete financial statements of installations made and many ill-considered electric suburban lines have been abandoned. Electrically operated roads must have a large excess of power station capacity. A steam locomotive is a more flexible unit than an electric locomotive and a steam-operated road is not subject to tie-ups due to burned out cables, blow-outs, etc. Much of the fuel economy claims made for electric operation are based on unwarranted assumptions.

Facts Relating to Regenerative Braking, Fuel Economy and Maintenance

C. H. Quinn, chief electrical engineer (N. & W.) said that if we are to maintain our standing in the commercial world, our railroad facilities must go forward and keep pace with the commercial development of the nation and that for this reason effort should be concentrated on the development of freight locomotives which can meet coming requirements. Freight car capacities, he showed, have increased 100 per cent during the past ten years, while steam locomotive capacities have increased only 10 per cent. By comparing fuel consumption of the electrified division of the Norfolk & Western with tests made on modernized Mallet engines under similar operating conditions, Mr. Quinn showed a fuel saving of 29.3 per cent in favor of electric operation. In answer to a query on regenerative braking, it was pointed out that during the past five years twenty thousand 3,250-ton trains have been taken down a 2.3 per cent grade, using only regenerative braking, without a single failure.

A. L. Ralston, mechanical superintendent (N. Y., N. H. & H.) compared the thermal efficiency of the 3,000-volt direct current system with the efficiency of the electric locomotive as given in Mr. Muhlfeld's paper. It is stated that on the New Haven, the efficiency at full load was 8 per cent; at 75 per cent load, 7.8 per cent; and at 50 per cent, 7.4 per cent. To prove greater reliability of electric service, he cited the fact that there was only one failure for every 21,000 miles run by electric locomotives and a failure for every 4,000 miles run by steam locomotives. He stated that the records of the New Haven showed that in slow freight service, approximately 25 kw. hours were consumed per 1,000 gross ton miles in freight service. The coal per kw. hour averaged 2.92 lb. and the line loss was 7.1 per cent. The fuel consumption in passenger service was 9.3 lb. per car mile on the electric division while the average for steam operation on the New Haven was 19.3 lb. per car mile. With coal costing \$5.00 a ton, the net saving through electrification was \$393,000 a year.

In freight service, electric locomotives consumed 84 lb. of coal per 1,000 gross ton miles while steam locomotives aver-

aged 199 lb., the saving in this service being \$268,000. In switching service, the consumption of electric locomotives was 38.3 lb. per mile and for steam operation, 106.8 lb. per mile, a saving of \$94,000. The electrification was therefore responsible for a gross saving in the cost of fuel amounting to \$755,000 annually.

The opinion was expressed by W. F. Kiesel, Jr., mechanical engineer of the Pennsylvania, that electric operation does not save coal and he produced figures obtained from locomotive tests to substantiate his opinion.

F. H. Hardin, chief engineer of motive power (N. Y. C.) stated that electric locomotives require back shop facilities as well as steam locomotives. Figures shown on the maintenance costs of New York Central Mallet locomotives, including shop and engine-house repairs, were from 24 to 37 cents per mile as against the estimate of 60 cents offered by Mr. Armstrong, and Mikado locomotives on the N. Y. C. show a fuel consumption of 125 to 130 lb. of coal per 1,000 gross ton-miles as against the estimate made by Mr. Armstrong of 158.

Broad Features Outlined

W. L. Bean, assistant general mechanical superintendent, while speaking for the steam men, presented an unbiased discussion based largely on his own experience. The following is an abstract of his remarks:

The prime factor to be considered in any engineering enterprise of commercial nature is the economic result of the entire specific project. Results of sub-projects in themselves are important and consideration sometimes of a multitude of factors of minor or more than minor nature must be sufficient, even to the last detail, but partisanship in championing some of the sub-factors to the exclusion of others is undesirable and of course does not represent the best of engineering procedure.

It must be conceded broadly that electrical operation requires less coal per unit of traffic handled than steam operation. How much less depends on the specific conditions. Likewise, the mileage per unit of electric equipment is ordinarily greater per unit of time. On one largely electrified road, express locomotives average 27 per cent more miles per day per locomotive owned than steam power in similar service. However, the first cost of the electric engines per unit of capacity was 84 per cent greater than in the case of steam. Therefore, the fixed charges are greater for the electric engine per unit of service.

A few words respecting comparative flexibility, especially in service of a character which demands it, may be of interest. A certain modern passenger electric locomotive will handle a heavy train of Pullmans at high speed on a through run with few stops such as would require a modern Pacific type steam engine of about 43,000 lb. tractive effort. However, to operate the electric engine in heavy local service over the same distance is impossible because of the heating caused by frequent starting. In such service, the maximum train which can be handled by the electric locomotive can only approximate what can be handled by a steam engine of about 30,000 pounds tractive effort.

Realization of the extent of accumulation of wear and tear, both electrically and mechanically, makes it difficult to understand just how railroads are to maintain electric locomotives without back shops unless they job the work out to manufacturers of electrical equipment.

Regarding the design of the machinery of a steam locomotive being utterly circumscribed by the necessity for tying it up to a steam boiler, the statement can be made that some modern high powered electric locomotives are so compact with apparatus, both inside the cabs and beneath, as well as on top, that additions to or enlargements of details, even of a minor nature, are well nigh impossible. Furthermore, this is not peculiar to AC-DC machines.

When one comes to attempting the solution of the problems attendant on the heating of passenger trains, electrically drawn; to find room for the boiler, water and fuel oil storage auxiliaries, etc., and keep within weight limitations, the difficulties are very real and certainly lead one to the conclusion that on electric passenger power the boiler is circumscribed by electrical apparatus.

It appears that when a railroad goes in for electrification, it must settle on some type of lay-out, the main characteristics of which are fixed. Extension must either be along the original plan as to power characteristics, distribution or collector apparatus, or else vast sums must be spent to re-vamp the existing plant if the new lay-out is not to be largely separate and independent with all of the inherent disadvantages of non-interchangeability and lack of flexibility.

The steam locomotive, except in a moderate way as to clearances and weight limits, has a wide range of application. Railroads loan steam power back and forth with advantage usually to both parties, but no case comes to mind where electrical equipment for heavy traction can be interchanged.

The design and operating characteristics of steam power have developed far more along lines of possible common usage and practice. It is to be hoped that the lines of development of electrical facilities will tend to converge rather than diverge too widely.

Tangibles from a money standpoint can and should be segregated and set up in full scope on both sides of the case and conclusions based on the net result at the bottom line of the balance sheet. If fixed charges on plant, including equipment, plus maintenance charges, plus other out-go, outweigh the savings in fuel, plus other operating savings, the net result is a deficit and all manner of proclaiming isolated pecuniary advantages would not induce a careful investor to support the enterprise.

Discussion by A. W. Gibbs

After reading the papers on steam versus electric operation of railroads, I cannot but feel that both Messrs. Muhlfeld and Armstrong have been a bit too enthusiastic. Both methods of operating have their advantages and both have decided limitations.

In Mr. Armstrong's case his data is largely derived from mountain electrification, where the electric locomotive is undoubtedly at its best and the steam at its worst, and he has compared with it a type of steam locomotive whose coal and water rate is more than double that of locomotives which are especially designed for such service. Then on this mountain performance he reasons from the particular to the general application of electric operation. True, he puts in a disclaimer as to the particular steam locomotives referred to representing the best modern practice, which brings up the question—Why cite them at all?

It is not at all certain that the speed advantage claimed is by any means true where the steam locomotive is designed for the work.

Mr. Armstrong gives a comparative statement of the performance of two steam and one electric locomotive to which exception can be taken because the steam locomotives do not represent the last word as to those available, and the electric locomotive is on paper.

The table shown herewith gives data for a 2-10-0 type steam locomotive of which over 100 are in regular service and of which fortunately very full information is available from the locomotive testing plant. These locomotives were expressly designed to do all of their work within the economical range of steam distribution, the required power being obtained by increases in size of cylinders and steam pressure. While I have given the power at nearly the speed mentioned by Mr. Armstrong, the performance is excellent at double the speeds given, but the sacrifice in drawbar pull—from nearly

60,000 pounds at 14.7 miles per hour to about 43,000 pounds at 25.3 m.p.h.—would not be justified. The figures given are within the range where stoker firing is as economical as expert hand firing, with the additional advantage that the stoker does not get tired.

This is a special design in which the advantage is that it cannot be worked at uneconomical points of cut-off. At speeds and pulls where the usual design is also worked at an economical range its performance is about the same.

2-10-0 Type Steam Locomotive	
Weight in working order.....	371,000 lb.
Weight on drivers.....	342,050 lb.
Weight on engine and tender.....	532,000 lb.
Drawbar effort at 14.7 miles per hour, 45 per cent cut-off.....	58,900 lb.
Gross tons (2 per cent grade).....	1,280 lb.
Trailing tons.....	1,019 lb.
Coal per D. H. P. at this speed and cut-off.....	2.8 lb.
Tractive effort at 22 miles per hour, 40 per cent cut-off.....	42,500 lb.
Gross tons.....	923 lb.
Trailing tons.....	662 lb.
Coal per D. H. P.....	3.2 lb.
Tractive effort at 25.4 miles per hour, 45 per cent cut-off.....	43,600 lb.
Gross tons.....	948 lb.
Trailing tons.....	687 lb.
Coal per D. H. P.....	3.8 lb.

The Mallet performance given in Mr. Armstrong's paper is evidently that of one of the large compound locomotives. In all of these locomotives there is a tendency to choke up with increases of speed, due to increase of back pressure.

The same arrangement of limited maximum cut-off used in the 2-10-0 locomotive already described has been embodied in a simple Mallet now running. In brief, the improvements in the steam locomotive, if properly availed of, have much narrowed the field of economical electrification.

Stand-by Losses. While these losses are actual and large it is very difficult to fix their value, as they are so much affected by the use made of the locomotive. Where the average monthly mileage is low the stand-by loss is presumably high, and it is a part of good operation to bring up the average mileage as high as possible. When all is said the electric locomotive has still an advantage with respect to stand-by losses, provided there are sufficient trains in motion to smooth out the total demand on the power plant, which is assumed to be steam operated.

Weather. The independence of the electric locomotive of severe weather is another undoubted advantage, not so much because of the performance of the motors but rather from the avoidance of losses and delays due to ash-pit work and to frozen pipes and other parts, incidental to the presence of water on the steam locomotive.

Liability to Interruption. Electric operation is dependent on uninterrupted connection with the source of power. In the event of breakage of the line, especially of the overhead construction, the trains in the section involved are dead and cannot get themselves out of the way of the repair trains. On large systems it is customary to make great changes in the assignment of locomotives to clear up congestion at any point on the system; also, to avail of diversion routes on which steam trains may be moved around obstructions on the main line. The fact that the steam locomotive is a self-contained power plant is an immense advantage in this respect. In electric operation there is not this freedom of movement.

Speeds. The question of speed is evidently treated from the freight standpoint, for there has never been any question as to the speed capacity of well designed passenger locomotives, being far beyond that permitted by the rules. As I see it, the feature of high speed of trains is of less importance than uniformity of speeds of different trains. If tonnage trains had the same speed as preference trains, and could thus avoid the great delay due to side tracking of trains of inferior rights, far more would be accomplished than the mere saving in time over the division due to the increased speed.

Extent of Electrification. Where electrification is contemplated a very serious question is: What shall be its extent?

Naturally the desire would be to wipe out as many as possible of the extensive accessories to steam operation. If, however, it becomes necessary to operate steam trains over the electrified section, it will obviously be necessary to retain water stations and possibly fuel stations, provided the electrified section is sufficiently long. This operation of steam locomotives under their own power over electrified sections would be necessary in case of redistribution and possibly in case of diversions where the electrified section formed part of the diverted line. Therefore, the claim for economy in doing away with these features of steam operation would probably not be realized.

Mr. Muhlfeld's Paper. Mr. Muhlfeld ignores the fact that the modern improvements which have so added to the performance of the steam locomotives are potential only. It is common for instance to so carry water in the boiler that the superheater becomes merely a steam dryer and its value disappears. In many cases because of neglect of damper mechanism or from dirty flues little benefit is derived from improved appliances. Modernizing of steam locomotives calls for intelligent use of these devices.

Conclusions. The electric locomotive or electric operation has in many cases undoubted operating advantages because the power is generated in quantity at few sources and the power on any one train is not limited by the capacity of a self-contained portable power plant; sustained speeds are possible due to independence of fuel and water stations and, as a result of both these conditions, better use can be made of a given stretch of road.

Electrification does not at all obviate the numerous class of delays due to the train itself, such as hot boxes or other of the numerous derangements which when combined so much retard the movement over the road. Electrification does not obviate that class of delay arising from necessary classification on line of the road to meet terminal requirements. Where the terminal conditions limit the capacity of the road as a whole electrification is not the remedy.

The relative cost of repairs of both classes of equipment cannot be fairly stated at the present time because maintenance conditions are so abnormal and because the most modern locomotives of both classes are too new to have reached a stable condition, this being especially true of the electric one. While the indications are that the maintenance of the electric locomotive will be less than that of the steam, it must be remembered that the electric locomotives are dead affairs without the necessary electric generating, transmitting, converting and track appliances, all of which are an added expense, due solely to electrification; hence the cost of maintenance of all of these, in addition to that of all of the locomotives, divided by the locomotive mileage, is the real treasury cost of maintenance per locomotive mile.

It is to be noted that practically all of the electrifications on steam railroads so far have been based on local conditions. In the electrifications in and around cities a moving cause has been the elimination of smoke and other objectionable features incidental to steam operation, and the possibility of increasing the capacities of the passenger terminals. On the Milwaukee road it was the utilization of available water power. On the Norfolk & Western it was to secure increase in capacity on a congested mountain division with tunnel complications.

If, after careful consideration of the road, based on actual train sheets for the heaviest actual or probable congested operation; the capacity and number of active and available locomotives required; crediting the operation with incidental savings which may be effected, and eliminating expenses peculiar to steam operation; it appears that there would be economy in electrification, either from actual savings or better operations, or both, it still remains for the management to decide whether the money required can be spent to better advantage for electrification than for some other features.

LOCOMOTIVE TERMINAL AS AN OPERATING FACTOR*

Satisfactory Locomotive Operation Dependent
On Adequate Locomotive Terminal Facilities

BY L. G. PLANT

Associate Editor of the *Railway Mechanical Engineer*

THE importance of the locomotive terminal as an operating factor lies clearly in the fact that both the quantity and the quality of work performed by every locomotive depend wholly upon the character of the attention which it receives at the end of the run. The most efficient locomotive may become wasteful or the most powerful locomotive be incapacitated by careless handling or neglected maintenance at the locomotive terminal. When we stop to consider that the average locomotive spends the better part of each day in the terminal and that its ability to render useful service during the remaining hours depends upon the care which it has received at the terminal, it must be evident that the locomotive terminal is a very live factor in the operation of any railroad.

The effect which a terminal can have upon the performance of every locomotive is so very obvious that any broad plan for the betterment of operating conditions must take into consideration the question as to whether a further expenditure in terminal equipment or improvement in terminal methods will not enable us to get more useful work out of our locomotives without a corresponding increase in operating expenses.

We are today operating bigger locomotives than were thought practical twenty years ago and some of them are equipped with devices designed to increase the efficiency and capacity of the locomotive beyond what was considered possible ten years ago. But we are handling many of these locomotives through terminal lay-outs and in enginehouses that were designed over thirty years ago with small margin for subsequent development. Thirty or forty years ago the locomotive terminal was hardly regarded as an operating factor; other causes determined the hours that a locomotive was available for service and there were fewer repairs required in the roundhouse because the locomotives were subject to less intensive operation, because all of their parts were much lighter

and because of the willingness with which the engineers cooperated in those days in the maintenance of their locomotives.

Function of the Locomotive Terminal

This brings us to a consideration of what is now the function of a locomotive terminal. It must, in the first place, afford adequate current maintenance. It may be possible and economical to concentrate the larger share of this burden at one of two adjacent terminals, but there are few terminals at which locomotives can be regularly turned without requiring the attention of mechanics. It may also be anticipated that the inspection required by the government will grow more insistent so that there are practically no locomotive terminals today in which adequate maintenance is not regarded as the foremost problem.

Generally speaking, terminal maintenance should be of such a character that the locomotives will continue to operate at full capacity and maximum efficiency between shoppings. Not only this, but the organization and facilities at every terminal should be adequate to keep all locomotive fuel and labor saving devices in working condition. Inability to properly maintain such devices with the terminal facilities on many railroads has been one of the most serious conditions tending to limit their full field usefulness. It is inevitable that locomotive terminals will be called upon to execute an increasing variety of heavy repair work, and it is imperative that they be so equipped that this work can be done without infringing on what may be described as the routine functions of the enginehouse.

The assignment of one or more stalls in a busy roundhouse to locomotives undergoing heavy repairs where the facilities are inadequate and the work consequently allowed to drag indicates a failure to comprehend the true function of a locomotive terminal. But, on the other hand, if the facilities are such that this work can be done expeditiously and economi-

*From a paper presented before the New England Railroad Club on November 9, 1920. An abstract of the concluding portion will appear in a subsequent issue of the *Railway Mechanical Engineer*.

cally this will do more than any other factor to prolong the useful service of locomotives between shoppings as well as lessen the ultimate maintenance cost.

Importance of Prompt Terminal Movement

A locomotive is of value only when it is performing useful work, and as it can only perform useful work when it is in service, it is startling to note how small a percentage of time locomotives on many railroads are in actual service even when traffic demands are very heavy. This is not necessarily a situation for which the mechanical department is responsible as the manner in which the power is dispatched by the operating department may cause much lost time. But terminal management and the terminal facilities at the disposal of the mechanical department are in most cases the controlling factors.

The cost of a locomotive is no index to what its actual value to the railroad company may be. If it is not a modern locomotive and the demands for power are such that it can be spared from active service it is valueless for the time being and should be stored for some future emergency. If on the other hand it is an efficient unit and the demands for power are pressing, it may easily be worth one hundred dollars for every hour that it is in active service. The value of locomotives will inevitably increase, and with an era of intensive railroad operation before us, we are unquestionably facing the ultimate pooling of all locomotives.

These facts only serve to emphasize the tremendous importance of speed in terminal operation. The function of the locomotive terminal is not only a matter of maintenance, but the execution of repairs and the routine operations of fire cleaning, coaling, sanding, washing and so on, within the shortest possible time. The significance of the prompt execution of these functions will be more fully appreciated when applied in principle to any railroad on which the demands for power are particularly heavy. Assuming that 1,000 locomotives are in service on an average of ten hours each day; if the terminal detention could then be reduced an average of one hour per day, this would be equivalent to an immediate increase of 100 locomotives in the number available for service.

It is the physical equipment, the organization and management of the terminal that determine its capacity to fulfill these important operating functions. Each new terminal development presents a unique problem which can best be solved by engineers acquainted with local conditions.

Essentials of Terminal Equipment

The essential features of locomotive terminal equipment may be roughly divided into outside equipment including the track lay-out, fire cleaning facilities, coal chutes and sanding apparatus; and the equipment which is distinctly a part of the enginehouse and adjacent shops. Where lack of foresight has not set a limit to the space available for expansion, trackage should be expanded to the fullest extent possible. A single track lead over which locomotives move to and from the roundhouse is inexcusable. Where trackage is ample, a well-defined routine for the movement of every locomotive can be strictly adhered to. With three or more tracks available, a majority should ordinarily be assigned to in-coming locomotives. As a general rule a number of short leads are preferable to a single long lead, as this enables one locomotive to move independently of other locomotives. Where the number of leads is restricted, frequent cross-over switches should be placed so as to reduce the liability of blocking the movement of any locomotive.

From an operating standpoint, the relative merits of various means for coaling and sanding locomotives may be gaged principally on the basis of reliability and capacity. Since the operation of these facilities reflects an operating charge, it may be well to consider the relative cost of opera-

tion, but this is not a circumstance to the necessity for reliability in operation and capacity, not only for the total daily quantities of coal and sand, but for the number of tracks served. While there may be some advantage in locating these facilities so that coal and sand may be taken together, there is apparently no real necessity for this, as it is not usually practical to deliver both coal and sand without moving the locomotives during the operation.

The arrangement of fire cleaning facilities and ash handling apparatus is undoubtedly the most vital feature exterior to the enginehouse. Whereas the time consumed in taking coal and sand can hardly be in excess of ten minutes, the time over the ash pit may easily consume one or two hours unless this movement is subject to the strictest supervision and the facilities are reasonably adequate. And yet these facilities at a very large number of so-called locomotive terminals are of the most meagre and primitive character.

Important Details in Terminal Equipment

No single feature about the terminal shows a greater variety in design than the locomotive ash pit. While we are accustomed to everything from an ordinary stretch of track on which the ashes are unceremoniously dumped, to extensive subterranean vaults from which the ashes are removed by mechanical conveyors, I am inclined to think that the water pit with a single gantry crane spanning three or four locomotive tracks and a single cinder loading track will prove to be the ultimate type best suited to meet the demands of intensive terminal operation. The transverse pit serving several tracks is preferable on general principles to the longitudinal pit serving but one or two long tracks. It may be stated that in the most recent terminal projects where space could not be regarded as a limiting factor, short transverse water pits serving three and four locomotive tracks are decidedly in vogue. In any event, the locomotive ash pan should be accessible to fire cleaners working on either side of the locomotive. This may be accomplished on water pits by spacing the locomotive tracks close enough together so that light movable platforms may be used between them or by providing an individual water pit with each locomotive track that is spanned by the crane.

Against the possibility of a break down on the part of the ash pit crane, a locomotive crane should always be available. In fact, the locomotive crane, ready for any emergency and capable of doing many things, must be regarded as indispensable to the operation of any real locomotive terminal.

The washing of locomotives with oil, water and compressed air appears to be an accepted time and labor saving practice. Some of the best results observed in cleaning locomotives by this process are noted at terminals where during the day shift every incoming locomotive is washed off en route from the ash pit to the enginehouse. Two men were engaged in the operation, which ordinarily does not delay the locomotive to exceed five minutes. This method would seem to have advantages over the practice of washing locomotives periodically and doing this in the enginehouse.

Enginehouse Design and Equipment

From an operating standpoint it may be said that there are some facilities which are indispensable to the enginehouse while the necessity for certain machine tools and other special equipment might depend upon the proximity of the terminal to the backshop. With the increasing weight of locomotives and growing appreciation of the value of every locomotive service hour, we are faced, however, with the practical necessity of doing more and more heavy repair work in the locomotive terminal.

It is important, therefore, that in all new terminal projects this situation be taken into account and the enginehouses be fully equipped for any repairs that may reasonably be anticipated. In some of the most recent and important terminal

developments, the enginehouse in reality approaches the modern erecting shop in design and equipment. These roundhouses comprise about thirty stalls occupying approximately a semi-circle. The depth of the house is 115 ft., having a cross-section which resembles that of an erecting shop of a three-bay construction. This includes a lofty bay in which a 75 ft. 15-ton crane operates along the outer side of the house and two lower bays at the turntable side. The outer wall, which rises to a height of nearly 40 ft., is comprised almost wholly of steel sash, which, together with continuous monitor windows 15 ft. in height over the lower bays, provides unsurpassed natural illumination.

Adjustable standpipes, resembling water cranes are located between the stalls in such a position that they may be fitted over each locomotive stack. All smoke and gases are then removed by means of a down draft system, so that there are no smoke jacks to interfere with the operation of a crane throughout the entire circumference of the house. This down draft feature is also relied upon in building fires, thus eliminating the use of the steam blower and blower lines. While a blower fan is installed to create the necessary down draft, the stack erected outside of the house is of sufficient height to effect a strong natural draft when the fan is not in operation. Separate drop pits to serve trailing, main and engine truck wheels are installed. The machine tool equipment at these terminals ranges from a comparatively small number of machines located in an annex to the roundhouse to a full complement of heavy machine tools in an adjacent erecting shop. The annex equipment includes a wheel lathe, boring mill, planer, motor driven lathes and unwheeling hoist, while the shop adjacent to other engine houses has the traveling crane and other equipment conventional to erecting shop lay-outs.

In fact, it is not beyond the range of possibilities to conceive of a development in locomotive terminals along these lines that would supersede many of the functions of the central erecting shop. While this is a subject more closely related to locomotive maintenance than to operation the question may well be raised as to whether better results could not be obtained from an operating as well as a maintenance standpoint if facilities were such that it would be practical to keep locomotives in good condition by frequent and adequate terminal repairs than by executing only the most urgent repairs in the terminal and relying largely on periodical back-shop operations.

The Most Important Facilities

Of the particular features regarded as essential to the most successful operation of terminal enginehouses, those which tend to reduce labor costs are of the first importance. On this ground a traveling crane or electric tractor that would have been considered an extravagance ten years ago might well be regarded as a necessity on the basis of present labor costs.

Splendid results, however, can be obtained by equipping the roundhouse with two jib cranes between each stall located so as to swing over both ends of the locomotive boiler. It is entirely practical to build a jib crane with a toggle joint which will enable it to swing in a complete circle of 15 ft. radius about the column (as described in the August, 1920, issue of the *Railway Mechanical Engineer*, page 544) and to equip these jib cranes with two ton chain hoists. In fact, some foremen would prefer a roundhouse well equipped with jib cranes of this character to having a traveling crane where the repairs required are not too heavy.

The only definite suggestion which can be advanced in regard to this feature of roundhouse equipment is that in all new projects where the development is on an extensive scale the enginehouse should be made ample in size and equipment to allow for a wide variety of repair work without interference with the routine operating functions. The equipment in

such cases should include the overhead traveling crane and downdraft ventilating apparatus. Where the activities of the enginehouse are limited to routine operating functions, the use of jib cranes are satisfactory and, if supplemented by an electric monorail or storage battery tractors, will meet every practical requirement.

Nothing need be said in regard to drop pits further than that they, or the equivalent in the form of an unwheeling hoist are essential to any locomotive terminal responsible for the maintenance of power in satisfactory running condition between shoppings. A number of well arranged drop pits are preferable to a single unwheeling hoist in the roundhouse, but where an annex is designed to care for the heavy repair work originating in the terminal, the unwheeling hoist would appear to be the most practical apparatus for such shop facilities.

It may also be said in a general way that the heating of enginehouses by steam or air even in the southern states is essential and that good ventilation and lighting are very important. Good floors will further contribute indirectly to the prompt movement of power through the enginehouse. The operation of the hot water washout system, on the other hand, has a direct effect on the operation of the railroad by reducing the time locomotives must be held in the enginehouse as well as exercising a very wholesome effect on boiler maintenance, and no locomotive terminal is in any sense complete without this equipment.

KINDS OF FUEL AND OPERATING COSTS*

In order to get the greatest return from money invested and the maximum of efficiency, it is necessary to have complete co-operation among the departments chiefly concerned in the purchase, inspection, distribution and handling of coal. Any failure of one or more departments to fully co-operate with the others in any particular feature or situation concerning fuel, exposes that railroad directly or indirectly to a loss. The effect of the changing grades of coal is soon felt, both on the performance of the engine and the operating costs. One of the most important effects is on the morale of the men. The modern locomotive long ago reached a size that is above the limit of human endeavor to fire by hand and also give the care and attention necessary for the economical use of fuel when different kinds are being continually furnished.

From an economical standpoint, prepared coal, even at a higher cost, is best, due to the elimination of delays caused by steam failures, and it is better adapted for stoker service, on account of being the proper size and free from foreign materials. In many cases the firemen do not break lumps to the proper size and remove foreign material before feeding the unprepared coal to the stoker.

With a grade of coal of a low heat value, and the locomotive equipped to handle it economically and successfully in short haul or local service, when the same uniform grade of coal is regularly furnished, the operating cost can be maintained at a minimum and a satisfactory service guaranteed. It has been proved that, with locomotives so equipped, when it became necessary to furnish them with a grade of coal of a higher heat value the cost of operation in the same service increased far more than the difference in the cost of coal, due largely to the draft of the locomotive and the lack of care and co-operation of the engine crews after the change of fuel was made.

With a grade of coal of a high heat value, usually furnished for long haul, heavy or first-class service, and with locomotives equipped to handle it economically, after a long established and satisfactory service has been maintained at

* From a paper presented at the convention of the Traveling Engineers' Association.

a minimum cost, this same service has been badly disarranged and the cost of operation largely increased when it became necessary to substitute a grade of coal of a low heat value to locomotives so equipped. In this case operating costs are increased because of the additional supervision necessary in the operating department, extra help necessary at intermediate points, extra pay to engine crews for fire cleaning, ash-pan cleaning, etc., required operating agreements, which accrue before changes in the construction of the equipment can be made. Added to this is the maintenance of the engine.

Because of the scarcity of coal at the present time, railroads are using a large amount of commercial or confiscated coal, which disrupts the regular assignment and raises the price per ton far above the regular contract price.

Some mechanical coaling stations have a tendency to separate run-of-mine coal so that lumps will all be on one side and fine coal on the other. Nothing is more discouraging to a fireman than to go out on the road with a heavy hand-fired locomotive supplied with fine coal and then see a yard engine coaled with clean lumps.

We recommend standard nozzles, front ends and equipments, but it is impossible to maintain them as standard without some knowledge of the character of the coal to be used, as it requires time (which is money) to make changes in locomotives to meet requirements of frequently changing coal. After locomotives are once equipped to handle a certain grade of coal, it is impracticable to be continually changing the front ends to suit different grades.

Distribution

It is a prevailing practice that fuel distribution be left in the hands of the fuel accounting or purchasing department. This practice is approved by the committee when coal of the same grade or heat value is purchased exclusively; but on any division or system where various kinds of coal of different grades are used and the grade and quality of the coal are known, the distribution should be under the direction of the officers of the locomotive department, who maintain the power and know its condition and are better able to state where various grades can be used to the best advantage.

An important feature of fuel distribution is to order and insist on the proper kinds of cars. It means an item of increased expense when the unloading has to be done contrary to the usual method.

Pulverized Coal

For good financial reasons, during the war period the railroads practically abandoned experimenting with and using pulverized coal. No doubt in the near future they will give this subject deserved consideration. Experiments made in the past seem to prove that there is much merit in the use of coal prepared in this manner. While many are enthusiastic relative to its merits, the committee has been unable to get any definite information of statistics relative to its regular use in locomotive practice.

Storage

Storing should preferably be done at the coaling stations or power plants, but when this cannot be done, coal should be stored as near to the point of consumption as possible.

So far as it can be brought about, only one kind of coal should be stored in the storage pile. Experience indicates that mixed coal loses more of its value and is more liable to spontaneous combustion while in storage than coal of one kind, under the same conditions. Chemical tests show losses of from one to five per cent if coal is kept in storage for periods from a few months to several years. Stored coal may not ignite as quickly as fresh coal, although there may be no difference in the B.t.u. value by test.

Oil

With the increased demand for domestic crude oil, from which nearly all of our lubricating oils and greases are made and upon which even the industrial life of the nation depends because of the great increase of internal combustion engines that can use no other fuel, it becomes almost a crime to waste this grade of crude oil as a steam producer, in so far as railroads are concerned. Unless greater fuel oil deposits are discovered and the cost of production decreased, which does not seem possible at this time, the most recent statistics on the production, storage and consumption of oil as a fuel clearly indicate that the day is not far distant when it will be prohibitive for locomotive use and it will become necessary to use some form of power obtained from a lower grade of fuel.

The report was signed by J. A. Mitchell (N. Y., N. H. & H.), chairman; E. F. Boyle (Sou. Pac.), H. H. Kane (Sou. Pac.) and G. V. McGlinch (M. C.).

Discussion

It is evident that the shortage of coal for the past year has led to extremely unsatisfactory conditions with respect to locomotive fuel and these conditions have clearly demonstrated the desirability of the maintenance of a uniform supply of coal on each division.

Several systems of distribution were briefly described. On the Louisville & Nashville coal is billed direct from the mine to the division, each division thus securing a uniform quality of coal, always from the same mine. Where coal is shipped from off the line, however, this practice was objected to and some system of distribution after the coal is received on the line seems to be necessary.

The abuse of the reconignment privilege was referred to as one of the causes of coal car shortage, the cars thus being tied up under load so far that in some cases the roads are unable to get cars for their own coal and must confiscate anything available.

Referring to the difficulty of securing uniformity in the distribution of coal under present conditions Robert Collett described the method being employed on the New York Central. A statement is issued periodically showing the distribution as it should be made, in comparison with the actual distribution and giving the per cent of incorrect distribution. This served as a lever to bring about improved conditions.

An Accident Near Manx, Nevada, Due to Spreading Rails in Which the Entire Train Left the Track, Causing Four Deaths

A View of the Readville Shops of the N. Y., N. H. & H.

CLOSING SESSIONS OF C. I. C. I. & C. F. A. CONVENTION

Handling Tank Cars, Loss and Damage, Passenger Car Maintenance and A. R. A. Billing Discussed

THE PROCEEDINGS of the opening sessions of the convention of the Chief Interchange Car Inspectors' and Car Foremen's Association were published in the November issue of the *Railway Mechanical Engineer*. At the conclusion of the discussion of the Rules of Interchange, as reported in the previous number, President Gainey introduced J. E. Grant and T. J. O'Donnell, special agents of the Bureau of Explosives, who addressed the convention.

DUTIES OF CAR INSPECTORS IN HANDLING TANK CARS

BY J. E. GRANT

No other rolling equipment of the American railroads today claims as much attention from the Bureau of Explosives as the tank car. It represents the development of a shipping container by means of which more lading of a character classified as dangerous by the regulations of the Interstate Commerce Commission and Canadian Railway Commission is transported than in any other way.

There is no class of car which should have the careful attention of a car inspector on the line or at an interchange point more than the tank car, and in view of its great importance in freight traffic, it will be interesting to trace briefly its development.

Tank cars are in a distinctive class from the fact that notwithstanding the enormous volume of their traffic, they are almost entirely privately owned. Of a total number estimated at about 125,000 the railroads own only about 15,000 of these cars.

Their range of ownership among the users themselves resulted during the first years of their existence in construction along the lines of individual ideas and until the year 1902 not much attention was paid to details of strength, materials or design provided they were mounted on frames and running gear capable of holding up in the general stream of freight traffic. In that year, 13 tank cars of naphtha were involved in an accident and as the result of the fire and explosion of several of the cars which followed 24 employees and others were killed and 291 injured.

Work of the Tank Car Committee

One of the results of investigation of this accident was the appointment of a Committee on Tank Cars by the Master Car Builders' Association. This action was at the request of the American Railway Association and the committee was charged to investigate and report on the question of proper design and construction of tank car equipment for the safe transportation of volatile oils.

It was found that the tank cars were inadequate to meet safe transportation requirements and recommendations were made to require strengthening of those already in existence, safety valves for the relief of internal pressure and the adoption of new standards for future construction of this class of equipment.

In 1910 the recommended practice was adopted as standard and the committee relieved. The following year, 1911, a Tank Car Committee was again appointed to take up the question of the shipment of liquefied petroleum gas or casing-head gasoline in tank cars in co-operation with Colonel B. W. Dunn, Chief Inspector of the Bureau of Explosives. The year 1912 marked the development of the insulated tank car for liquefied petroleum gas and also for liquid chlorine gas.

Up to the time of the first appointment of the Tank Car Committee the principal products of the petroleum industry shipped in tank cars had been kerosene or illuminating oil and the lubricating oils. Gasoline was more or less a by-product of their manufacture and internal combustion motors had only fairly entered their stage of development for industrial and automobile use.

Hazards in Shipping Gasoline

A steady and rapidly increasing demand for gasoline as motor fuel has continued from that time until today the supply is inadequate from the refining of the greatest petroleum production in our history. To meet the increasing demand it has been found necessary to supplement the refining process by manufacturing gasoline by liquefying the gases from oil wells. This gives the product called liquefied petroleum gas or casing-head gasoline, which either alone or blended with heavier products is capable of causing and has caused

more damage and trouble than any other commodity ever shipped by rail.

Its dangerous nature is due to its great volatility or rapid evaporation and its vapors like those of ordinary refinery gasoline are so highly inflammable that they will ignite and flash back at great distances from their liquid source. Casing-head gasoline also has a very low boiling point and a high vapor tension or pressure which results from a rise in temperature. These hazardous qualities call for the tank cars in which it is shipped to be in perfect condition as non-leaking containers and also have provision for automatic relief of interior pressure which may develop in the tanks beyond a point which might strain them or cause them to rupture. This protection, which is very important, is afforded by safety valves.

The regulations and tank car specifications provide for tanks and valves to be kept in serviceable condition by periodical tests which have to be reported to the Chief Inspector of the Bureau of Explosives. Barring accidents or misuse it may be assumed if the stenciled dates which must appear on each tank show such tests to have been made within the prescribed time limits that the tanks and valves are in proper condition for service.

Rules Safeguard Movement of Tanks

Unless involved in such an emergency as a wreck, tank cars should not be in a condition to permit the escape of an inflammable liquid, and without such escape there is no hazard of fire. Yet reports reach the Bureau of Explosives daily of instances where leakage is found at seams, rivets, bottom outlets or through insecurely closed domes. A. R. A. rule 3, section (e) shows that such a car (empty or loaded) will not be accepted in interchange. These conditions indicate either that the car was offered to the railroad in that condition by the shipper, or that the leakage developed in transit. If the car was shipped in that condition, the initial carrier failed through its inspector to comply with paragraph 1822 (f) which prohibits its acceptance. If leakage developed in transit, the car should have been taken out of the train as soon as discovered and if the leakage could not be stopped, the contents of the tank should have been transferred into another. This action is called for in rule 2, section (b). In these operations or any other where there is an escape of inflammable liquid the principal thing to bear in mind is that lights and fires must be kept away.

This precaution is the most important of all and from various sources of ignition up to a distance of 480 ft. the records of the Bureau of Explosives show tank car fires to have been caused by locomotive sparks, hot coals, lighted matches, cigars, cigarettes, back firing of automobiles, oil or gasoline lanterns, torches, switch lights, fireboxes, steam cranes and other similar causes.

Handling Leaking Tank Cars

Without doubt the most serious situation to deal with is that resulting from wrecks and derailments. Tank cars then lose their contents through leakage caused by rupture of the shells or displacement of bottom outlet valves or it is necessary to transfer their lading into other cars before the wreckage can be cleared up. In nearly every case where leakage takes place through damage to the tanks there is an immediate ignition from the sparks and friction of grinding metal in the wreck. A leaking tank is a reservoir which feeds fuel to the flames and seldom if ever are means available to extinguish the fire until it has gotten beyond control. Water will spread instead of quenching it and if it cannot be smothered by the use of earth, steam or wet blankets, all efforts should be directed without delay to saving other property.

In wrecks involving tank cars which do not leak or where there may be leakage which does not ignite, the action of those handling the situation is most important. The first thing

to do is to move away all lights or fires of every description and police the location with reliable guards to see that this precaution is strictly observed. Any leakage should then be stopped or reduced as much as possible. The next step is to dispose of the leaking liquid so it will not create a hazard. This is usually done by draining into holes in the ground and then covering the area with loose earth. While this may delay the handling of the wreck it must be remembered that there is no possible way of safely handling such wrecks while gasoline is freely leaking from tank cars or while a heavy leakage has not already been taken care of.

While gasoline is actually escaping all lights and fires should be kept at a distance, this distance being necessarily much greater on the leeward than the windward side. The vapor being heavier than air flows along the ground and settles in low places. It may travel a considerable distance with the wind, though when the air is quiet it will tend to form a layer along the ground. With the exception of closed electric lights all necessary signal lights and lanterns should be kept elevated and on the windward side. After allowing reasonable time for escape of vapor from the leakage and buried liquid, a steam crane may be brought up on the windward side, but not within a distance of 500 ft. The least injured cars should be first handled and if it appears that further leakage is to be expected such tanks should either be transferred or emptied into holes or trenches in the ground for burial.

Safe Methods for Transferring Contents

In transferring lading from wrecked or leaking cars several railroads are successfully using the air pressure method and the steam pump. Air pressure will not be practicable where there is any appreciable leakage from the tank, and on some lines it is thought that whether or not the tank is ruptured the steam pump is better. These methods are now under investigation by the Bureau of Explosives and a circular will soon be issued giving details of various types of such equipment which have been found to operate satisfactorily.

Up to this time the bureau has details of the successful use on one of the largest Eastern lines, of the single acting Blake pump by steam taken from cranes or locomotives. One wreck train is equipped with one of these pumps 7 in. by 5 in. by 10 in. and another train with one 8 in. by 5 in. by 12 in. At a point on the same line where movement of cars to be transferred is safe, they are hauled to an oil plant, and the lading is pumped into other cars by triplex No. 4 or No. 6 steam pumps after being drawn into a ground line. At two of its shops, this road also transfers by air pressure of 6 to 8 lb. per sq. in. through piping from the bottom outlet of one tank to the dome of the other.

A large Western line is using the Blake type of pump 6 in. by 4 in. by 6 in. as a part of its wrecking equipment with standard Westinghouse piping where it is possible and standard air brake couplings. Air from the train line of the wreck train is used to operate the pump.

Transferring by Air Pressure

Another road in the Northwest has used air pressure from the train line when tanks are not leaking. A substitute dome cover is placed in position, which is tapped through for two 2-in. pipe connections. One passes through to the bottom of the tank for the discharge and the other merely admits air into the dome. The discharge pipe has an extra joint for lengthening or shortening to fit the diameter of the tank. A rigid discharge pipe, however, will not completely empty a tank that is not plumb.

Several roads in the Midwest are using air pressure from the train line with a special dome cover and flexible non-collapsible hose for the discharge line. This arrangement by dropping the end of the discharge line into the lowest part of the tank will practically empty it of all its contents.

The general principle in regard to pumps for such use is that any pump which will operate on steam will also operate on air; and since these operations are to handle liquids under low head, any good type of steam pump having relatively large water cylinders and metallic valves should answer the purpose. In addition, since it should be portable so as to permit placement in various locations necessary for use, lightness is also essential.

With the air pressure method it will be understood that the safety valves on the tank will not permit use of more than 25 lb. per sq. inch, so no attempt should be made to exceed that amount. It has been demonstrated that pressure considerably lower will accomplish the necessary results. The special circular which I mentioned will be issued by the bureau at an early date and will give data covering various details of the required materials and assembly of apparatus together with rate of flow in transferring and approximate costs.

Other Dangerous Shipments

Other commodities with inflammable hazards such as alcohol, benzol, benzine, naphtha and carbon bisulphide are transported in tank cars as well as acids, sulphuric and mixed, which are highly corrosive and therefore classed as dangerous. Liquid chlorine gas and sulphur dioxide, both highly volatile and poisonous, are considered as especially dangerous because of this characteristic and require specially strong and insulated cars the tanks of which are entirely welded and built without the use of any rivets.

While these last mentioned liquids possess hazards peculiar to themselves, the handling of gasoline is by far the most important by reason of correspondingly greater hazards due to its greater volume of shipment. It is estimated that such shipments now move at the rate of more than 3,500,000,000 gallons annually.

From 1910 to the beginning of this year 117 people were killed on the railroads in the transportation of dangerous articles, other than explosives. Of this number 97 or about 83 per cent were killed by gasoline. Of 1,079 people injured, 684 or 63 per cent were injured by gasoline. Of the property loss amounting to \$6,469,962 during those ten years, \$3,215,922 or over 49 per cent was caused by gasoline.

Gasoline More Destructive Than Explosives

These statistics indicate that gasoline in disastrous results during transportation has shown itself to be many times as destructive as explosives and by a wide margin in point of hazard to life and property the most dangerous commodity from a railroad standpoint. The worst accident which has occurred in the transportation of explosives does not approach in effect the tank car disaster at Ardmore, Oklahoma, in 1915 when 47 persons were killed, 524 injured and property damage reached nearly \$2,000,000.

In the face of this evidence of its terrible toll of life and property which has continued for years, the question naturally arises, "What is being done to prevent it?"

The Tank Car Committee with a membership composed principally of master car builders and selected as representing expert mechanical ability, has been faithful and untiring in its efforts to lay down requirements for the construction and maintenance of tank cars in the safest condition for such important service.

The Bureau of Explosives, with the advantages of research, investigations, the services of a skilled chemical staff and specially trained inspectors directed by a technical and mechanical expert, has had included in the regulations for safe transportation, rules which experience and a knowledge of dangerous products have shown necessary in proper preparation for shipment and safe handling in transit. These regulations have been supplemented from time to time by special circulars and bulletins, pointing out the lessons to

be learned from failure to observe proper safety precautions and giving valuable suggestions and recommendations for suitable action to cope with various dangerous situations.

Notwithstanding all these measures, the loss of life and property continues. Some of it is unavoidable, as it has been truly said that as long as railroads are operated, wrecks will occur. Much is preventable, however, and the share of responsibility which falls upon the car foremen and their inspectors in line and interchange work is by no means light.

Weak Points of Tank Cars

The present types of bottom outlet, dome opening and safety valves are three weak points of tank cars. On account of the fact that records show the bottom discharge outlet responsible for 95 per cent of the leakages from tank cars, the chief inspector of the bureau last year recommended its elimination entirely. This would necessitate unloading through the dome and the suggestion was not favorably received by the oil industry and tank car owners. Their acknowledgment of the inadequacy of this outlet, however, was immediately shown in co-operative action through the American Petroleum Institute to develop a leak-proof valve and a sub-committee of the Tank Car Committee has also been active along the same line. Several types have been investigated and a number are now installed on tank cars for trial in actual service tests. Improvements in dome covers and safety valves are under investigation to develop types which will not permit the escape of vapor.

In addition to the precautions I have mentioned I would suggest the importance of impressing strongly these points in the minds of your inspectors. Remember always that the warning on the placard attached to a tank car loaded with an inflammable liquid means just what it says, "Keep lights and fires away." A leaking tank car of gasoline is a fire trap and if you pass one through on your inspection it may cause the death or injury of one of your fellow employees and others along the line. A loaded tank car is top heavy and if a side bearing is missing or the clearances are too great it may rock off the track and cause a serious wreck.

Bottom Outlet Requires Attention

If the outlet valve is defective or not closed the outlet chamber in cold weather is liable to burst from the freezing of water which settles from the gasoline and leaks into it, and if you discover such a condition by detecting a crack in the side of the nozzle, serious trouble will be avoided later by prompt arrangements to transfer the contents into another car.

If your work is where loaded tank cars are received from shippers, satisfy yourself that the cars are being loaded with the valve caps off. Then you will know that the outlet valve is closed and if the valve cap is lost or the outlet chamber broken off the contents will not leak out. If you have any doubt that shippers are loading without this precaution, arrange to have some of the valve caps removed occasionally before the cars are pulled out to see if the outlet valves are closed and in proper condition.

Examine the stenciled test dates for the tanks and safety valves and if you find either or both overdue, the car should not be forwarded under load. Rule 3, section "p" of the Interchange Code tells you that tank cars, the safety valves of which are due for test within 30 days, will not be accepted. Rule 16 provides that a road having in its possession a tank car due for test of safety valves must make such tests in accordance with the tank car specifications, billing the owner for the cost of same. Rule 9 provides for this and requires a certificate for such test to accompany the billing repair card.

Rule 2, section "b" states that "A leaky tank car shall have stenciled on it, in letters three inches in size, adjacent to the car number, the words 'Leaky tank. Do not load until repaired,' and the owner shall be immediately notified. Sten-

ciling must not be removed until the tank is repaired." This rule is designed to show the owner or user that a tank must be repaired before further use and will apply most often when transfers of lading are made in transit. Another important rule is No. 32 showing delivering companies responsible for missing dome covers and safety valves.

Proper Use of Placards

Remember that all tank cars loaded with inflammable liquids must bear two cards showing the proper classification name of contents and four "Inflammable" placards. If these markings are lacking do not pass the car until they are applied by the shipper or if they become lost in transit see that they are replaced before further movement. Rule 36 covers this and rule 107 provides for the charge for the service.

Any tank car containing liquefied petroleum gas or casing-head gasoline must also bear three white placards on the dome, two on the sides and one on the cover to warn against its removal while any interior pressure exists. Do not remove the dome cover of any such car unless absolutely necessary and this only in a location safe from the danger of lights and fires and after pressure has been removed by raising the safety valve. The boiling point of casing-head gasoline is low and any agitation of the tank will be very liable to cause the liquid to rise and overflow.

Precautions to Be Observed at Night

Never go up around the dome of a loaded tank at night with an ordinary lantern or torch. Use an electric flash light or an electric lantern. In approaching tank cars at night be constantly alert to detect the odor of possible leakage, remembering that the sense of smell if normally developed, is a good guide to warn of such hazards and the great danger is that of igniting the vapors rising from the leaking liquid.

Familiarize yourself with the specifications for tank cars and regulations and rules governing their proper physical condition and placarding. Obtain through the proper official of your line and read copies of bureau publications dealing with the hazards and proper handling of tank car shipments of dangerous articles, especially Circular B. C. L. No. 189, Handling of Wrecked and Leaking Tank Cars and B. E. Pamphlets Nos. 20-I and 20-J, Condensed Instructions for Wreck Crews and General Mechanical Superintendents, Chief Car Inspectors and Car Inspectors.

The prime object of your association and the practical aim of your personal vocation is to maintain equipment in the required serviceable condition for safe transportation. This is common to the purpose of the Bureau of Explosives, and we should all use our best endeavors to meet our share of these responsibilities for successful accomplishment of the greatest enterprise in the world, the operation of the American railroads.

President Gainey thanked Mr. Grant, on behalf of the association, and introduced J. O'Donnell of the Bureau of Explosives.

Address by Mr. O'Donnell

The interchange man is first confronted with a dangerous article by the placard on both sides and ends of the car, placed there before the car reaches the inspector. The method of manufacture of these dangerous commodities known as explosives and other dangerous articles, must be open to the representative of the common carrier or the Bureau of Explosives. The United States goes back to the very beginning and sees that it is made so that it will be safe to transport. Quite a lot of the most dangerous of all explosives are not allowed to be transported. For instance, nitroglycerine and dynamite that contains more than 60 per cent nitro-glycerine, except in gelatine form, and in this form the type of package is specified and limited in weight so that

each package can be handled practically by the effort of one man in an emergency. After doing that, if its shipment is to be presented in less than car load lots, there are certain labels designated for the dangerous articles other than explosives, alike in form and in marking. There is a tremendous safeguard in so doing because the freight handler knows them wherever he sees them, and so they are always alike. The labels are standard. The principal use of these labels is in warning the individual of a dangerous commodity; they also tell the kind of a placard to put on a car, for the car must be placarded.

One of the greatest problems that we had to deal with in the early days of this movement was the number of placards that were moving in transit. You can see that the fewer cards there were the greater the respect would be for them; that is why Rule 107 lays down a specific charge for removing cards that are unnecessary; also when placards are missing, a charge for applying.

The car load lots that you see moving are practically all loaded by the shipper, and he has to load according to a certain specified standard. The very bracing that he uses is specified. It must be no less effective than that laid down by the bureau for his guidance.

When the car arrives at interchange and you see the placard, a number of safeguards have already been taken, and the placard is there to warn you that you have a dangerous commodity in the car and you must handle it accordingly. You will also notice on the side of an explosive car that there are car certificates which state positively that the car passed a careful inspection; that it is a standard car of not less than 60,000 lb. capacity, and where possible it must have a steel underframe and friction draft gear. It must have no loose bolts. The roof must be sound, running gear in good condition, journal boxes packed in oil, and if there are draft bolts sticking through the floor they must be covered and beveled on the ends.

This car demands your most careful attention, and the rules laid down in interchange say you cannot offer such a car for transportation unless in proper condition. You cannot make any arrangements by which you can give that car to a connecting line if it is not in good condition. If it is discovered in bad condition on a receiving line, it cannot be moved back to you. That is a wise regulation because in a crowded terminal there is too great danger of shuffling these cars back and forth.

The interchange inspector is particularly interested in that car because he must go around it; see that from the outside it is in apparent good condition to travel; that the placards are on, and if there are any signs that the car has received rough treatment, he must open the car and inspect the lading. Some roads make a practice of opening all placarded cars on the receiving line; the regulations do not require that, but they do say if there is any apparent damage to the car, you must open it because the lading is of such a nature that you cannot afford to take any chances.

Another class of cars is that placarded "Inflammable." With explosives, unless there is a shock or friction, there is no danger of an explosion. But in approaching a car that is placarded "Inflammable" it is possible that it may be leaking, and bringing your lantern or lamp near, it will cause a fire from the inflammable vapors. So great care should be taken when you see an "Inflammable" placard. Above all things the warning on the inflammable placard should be strictly obeyed—never to bring lights or fires near that car, unless you know there is no leakage there.

Suppose you have a cut of cars moving on A road, transported to B road, standing on interchange, usually at night; it is dangerous for any inspector to take his lamp and begin to go down that cut of cars, not knowing but what some of the inflammable liquids may be pouring out and the wind

blowing that vapor towards the light. I have known of a case where the vapor has reached a fire 480 ft. away and flashed back.

The dominant idea when an inspector sees a placard should be that that placard is for a purpose and that purpose is a warning.

There are a few things I would like to say about tank cars. At St. Louis there are 1,250 tank cars placarded every day. The St. Louis plan is the ideal plan; that is, that every railroad company of any size that handles these tank cars ought to have a trained expert in the person of one of their inspectors whose particular duty it is to learn all he can about tank cars.

One of the best ideas I could leave with you who are in charge of men is to recommend that you take some man who you see is especially interested in this thing and encourage him—give him all the literature you can find on the subject, and when you have a leak or a wreck you will have a valuable asset in this man, who will detect danger at once if other men are careless.

There have been great improvements in tank cars. The head block is gone; the old patched sheet is gone; the old 40,000 lb. tank is nearly gone. The tank that had a shell like a patch of paper is gone. Now we have periodical tests. The 12 lb. valve is nearly obsolete. We have a 25 lb. safety valve, and in a little while we will have a bottom outlet valve, and we will have done a great deal.

I hope that what I have said to you will have some effect; that you will go home with a renewed idea that these regulations which you see for the safe transportation of explosives and other dangerous articles, as they appeal to the car men, will be renewed under your supervision; that the men will be given strict orders; that these are not railroad regulations; that they are Federal laws and must be obeyed. Some penalty is laid down, but we do not want to threaten a man with penalties, because a man who works under duress is not a good man. We want it done because it is the only safe way to do and because it is the law of our land. (Applause.)

Discussion

President Gainey: I want to thank Mr. O'Donnell for his instructive talk that he has given us this morning. I know that what he has said to you is from his heart.

Talking of examining cars on the outlet valve, a few years ago I knew of a case where a train was running along and the cap came off at the bottom and a whole tank of oil was lost. On examination it was found that the tank was loaded with the valve wide open, at a point where there was no inspector. In testing the cap it was found to have five threads and it did not tighten until it got to the last thread. The cap loosened and worked off. I think it would be well to take these caps off once in a while to see whether the valve on the inside of the car is closed.

E. H. Mattingley: As we have a representative here from practically every road in the United States and Canada, I would like to ask how many roads handling tank cars have supplied their inspectors and the men having to do with the handling of tanks, with an electric lantern as outlined by the speakers?

W. P. Elliott: I will say the St. Louis Terminal has.

A Member: The Pennsylvania has.

E. H. Mattingley: I would move that it be the sense of this body that we recommend to our superior officers that all railroads having to do with the interchange or handling of tank cars, supply their inspectors with a special electric lantern or flash light for the safe handling of such cars. (Seconded by W. P. Elliott.)

T. J. O'Donnell: While I fully agree with the motion, I am wondering if Mr. Mattingley realizes what a great expense that is. Wouldn't this motion be better. That every

car inspector be advised by the yard department when a string of cars pulls in, of the initial and number of every car that carries explosives or inflammable matter; then he will know where the car is and when to look for it. I think Mr. Mattingley realizes that while our suggestion is a good one, it probably would not be adopted right away because you would have to delegate one man to do that work. In our terminal we have tank cars going through 37 yards. I would have to have special men at different points. We accept from industrial plants large numbers, and our superintendents have recommended that when a car leaves the terminal each division superintendent will have definite notice what position that car has in the train, so that when our men start on it, they will know right away when to look for it.

E. H. Mattingley: How would you handle that car at night?

T. J. O'Donnell: Odor would be the first definite notice. The inspector should be extremely careful not to go near when the odor is heavy. I have never had an accident of that kind in our district.

J. O'Donnell: It seems to me that the most prolific source of accident is the switchman's lamp. I believe every one of us should keep that before us. It cannot be said that with the inventive genius of today, something could not be gotten up to take the place of that device which has caused many fires in tank cars. There is no use having a man with an electric flash light going to one particular car when you may have an engine passing, or a switchman going down to the rear end of his train with a lamp. Wherever it is known that leakage takes place, we have got to use an electric flash light or wait until daylight. But I believe it would be a good thing if this body would go on record to some extent favoring a change in our plan of lamps for inspectors. I would oppose all inspectors having flash lights for the same reason that Mr. O'Donnell does, but I do say that we ought to have them.

T. S. Cheadle: I think it would be a good thing to have the class of the car stenciled on it. I understand that class 2 could be changed to another class; when it is loaded the man loading ought to be required to change the class of that tank.

E. H. Mattingley: The object I had in mind was that safety first should be and must be recognized, regardless of cost. If the fires which these gentlemen have described are caused, and will continue to be caused, by the open flame light, then, regardless of what it will cost to equip railroads, something of this kind should be prescribed for the inspection and handling of tank cars.

We all know as car men that it is the first duty of the car inspector to detect the trouble. If he finds a leaking tank he notifies the yardmaster, or the proper man in charge of the yard which is concerned, yet the only way he has of knowing the tank car is leaking is by the sense of smell. How many car inspectors will attempt to make repairs and carry a flame light by night while making these repairs? Therefore, in justice to our car inspectors and in harmony with the safety first movement, I would recommend that switchmen and car inspectors who have to do with the handling of tank cars and other cars containing inflammable liquids or explosives, be provided with an electric light, or some improved method.

W. P. Elliott: I believe if you would poll the railroad companies, you would find that they are doing that now. The inspector is the man who is notified nine times out of ten and he will take care of it. When he goes down, he has got to have something besides his lighted lantern. It isn't necessary that each individual inspector have an electric lamp if they are kept on hand so that the men who need them may use them.

E. H. Mattingley: I did not mean that the entire car inspection force should be equipped with an electric lantern, but possibly two to six lights, as may be deemed necessary, could be provided, according to the number of tank cars re-

ceived at that particular yard. I think the lights should be there, but I fear that is not the case in a great many of our large terminals at the present time.

A. Berg: These requirements are already met on our line and have been for a considerable time.

(The question was put upon the motion and the motion carried.)

G. Lynch: Mr. Grant's paper and the able address of Mr. O'Donnell were both very instructive, and I move you that a vote of thanks be extended to these gentlemen and that their remarks be incorporated in the minutes of our meeting. (Seconded and carried.)

President Gainey next introduced E. Arnold, general claim agent of the Grand Trunk.

Address of Mr. Arnold

As a Canadian who has lived half his life on the other side, I want to welcome you to Montreal. The railroad organizations have had some of their most successful meetings in this town, and the Canadians as a whole are very fond of their American cousins. We believe about the same as you do, and the Canadian lines have followed closely all of the rules of the American associations and have respected and upheld them all the way through.

I have been much interested in the remarks of the representatives of the Bureau of Explosives. We have had some very heavy claims on account of the transfer of oils from tank cars containing a high class oil to other tank cars that were not properly cleaned. I have seen several claims amounting to from \$1,000 to \$4,000 because the cars to which the oil was transferred were dirty, or contained inferior oil, and thus damaged the oil and made it unfit for the purpose for which it was intended. I do not know whether the car men are vitally interested in that, but they usually decide whether a car is fit for transfer or not.

Another thing which I brought up personally before the A. R. A. is whether we cannot get tank cars with the valve at the top instead of the bottom. If the valve breaks the car may leak for hours and the train men are unable to stop it; consequently oil of the value of from \$2.00 to \$4.00 a gallon is leaking along the entire right of way. With all of our American and Canadian inventive genius we ought to be able to invent a tank car without a valve at the bottom. In the large oil districts we have endeavored to have a change of that kind brought about.

The A. R. A. executives are much exercised at the present time on account of the large sums we are paying out in loss and damage. It is a subject that has been very close to me for a number of years and consequently I am very much interested in it.

I have a circular from J. E. Fairbanks, general secretary of the A. R. A., calling our attention to the large sums and asking us to get together and see what can be done. During 1919 the Class I roads alone paid out \$104,000,000 during the year for loss and damage. A good deal of that was due to defective equipment, and I know during federal control and during the war we have not been able to keep our equipment up as it should be. In consequence there is a great deal of poor equipment going over the roads. Also, on account of the immense volume of business moving, we have not been able to pick out cars for certain commodities that require good cars, as we have in the past.

During federal control we did not examine the cars at interchange points as we did before. We did not take the seal records, and in consequence the sums paid for loss and damage were double.

We have recently been granted a large increase in rates, and it behooves us to give the public the service that they are paying for, and they are going to be more critical in the next year than before they paid the higher rate. They are going to expect us to give them good service.

The A. R. A. has ruled on defective equipment and said that the carrier supplying the car must make a proper inspection through a representative; must keep a book record of that inspection and must show that every time there is a claim presented for damages, and if they are not able to show that on loading the carrier will be charged with the full amount of the claim. Claims of that kind have been prorated on a through mileage basis, and it has been carried by all of the cars instead of the one that was very often at fault. Beginning September 1, unless we have a book record, we have got to pay the claim if we use a defective car. So it behooves us to give proper inspection in that respect.

There are a great many hopper bottom cars loaded with coal leaving the mines that are in unfit condition, and a car has to carry the coal to its destination. I would like to emphasize the importance of close inspection at the coal mines. There is a cry for coal all over the continent as there never was before, but I think we can get better repairs to some of these cars than at the present time.

Since 1893 our average claims have increased from \$30 to \$55. The courts all the time are ruling in favor of claimants. Up to a few months ago we paid claims on the basis of invoice value at the place and time of shipment. We would make a man show his invoice, but now the courts have ruled that we have got to pay the claim on the basis of the value of the goods to destination of consignee. It has made a wonderful increase in our claim payments because we are not able to determine the value of goods at destination.

We have many cases where refrigerator cars containing fruit and other things of that kind are run over several different roads. The drip pipes are supposed to be clear. They are iced and when they get to destination, from the Pacific to the Atlantic, we frequently find that the drip pipes are clogged and the car will have a foot or two feet of water, the doors are open, and we have a claim to pay. Refrigerator cars are largely privately owned cars. Get better inspection to protect your own road and to protect your connection.

We have the same trouble in connection with the bunkers and different parts. Many of the employees did not know what the different parts of the refrigerator cars were and were not able to carry out the instructions. Now we have a monthly meeting and we have been instructing all employees and examining them as to their knowledge of the car, just as they are being examined for safety and other appliances.

The Grand Trunk has had in operation for some time a claims prevention campaign, and the results have exceeded our most sanguine expectations. Without going into details or quoting figures extensively, I would say that broadly speaking our claim payments due to defects in service of one kind and another have decreased by 50 per cent.

I mean of course a decrease as compared with the earned revenue. The actual amount would be more in our favor were it not for the fact that the high cost of the commodities operates against us. To achieve this result required the co-operation not only of our own staff, but also the staffs of other lines. The benefit of better methods of handling freight which will accrue to any one particular road as a result of their own endeavors will be negligible if other roads are not moving in the same direction. The great bulk of traffic moves in car load lots, and it will be easily seen that handling with the utmost care over portion of the route will be practically of no use if the car is negligently handled on the balance of the journey. The damage in evidence at destination will be what is known as "unlocated damage" and the claim if paid will be prorated on a mileage basis so that the careful carrier pays a prorata amount equally with the careless one.

This condition cannot be overcome. The remedy is for employees to handle cars as if their own company only was involved and they were individually responsible for the arrival of the shipment at destination in good shape.

In the proper apportionment of claims paid as between car-

riers the members of your association play a very important part. Especially is this the case in losses from open equipment. When loss has been established and the claim paid, the next question is whether the loss is a located one or an unlocated one. This gives rise to the query, "How did car check at the junction point?" The answer to that question will depend to a great extent on the thoroughness with which the inspector carried out his duties or rather to what extent he carried the inspection.

The principal losses from open car equipment are coal shortages and parts of machinery. As regards the latter, unless in very exceptional cases, a junction examination will scarcely be sufficiently minute to say with certainty whether loss occurred or not. Such shipments are usually described as a carload of machinery and the parts can be and frequently are removed in transit without anyone being the wiser till check is made by consignee when it is found parts are missing. These cases rarely present any difficulty, it being pretty generally agreed by all having any connection with the adjustment of claims that such losses are unlocated and where settlement must be made as a result of suit or otherwise such claims are usually prorated from shipping point to destination.

In the case of coal shortages, however, a different situation presents itself. Here we have a case where the whole matter is in the hands of the railroad employees. The car is scaled and a certificate furnished to the mine owner giving details of gross, tare and net weights. The car arrives at destination, the consignee is advised of arrival and demands the car be weighed before he accepts it. He gives as his reason for this demand that a previous car accepted by him in apparent good order was ten tons short. On weighing this car a similar shortage is discovered and the carrier delivering the car is presented with a claim for the value of the shortage. In fact various firms refuse to accept cars of coal till weighed and rely on weights so obtained to press claims for loss.

Such claims must be recognized as the legal departments of various roads have ruled unless it can be proven conclusively all the coal loaded at shipping point was delivered at destination, less allowances if any covered by tariff, carriers are liable. Where shortages of quantities up to say five tons occur in transit either as the result of robbery or rough handling causing part of the contents to fall off the car, or of leakage developing in transit and being stopped without record being made on the waybill it will be conceded without question such losses would not be noted in junction inspection.

The number of heavy claims covering shortages of coal principally from Pennsylvania points to destinations in Ontario induced this company to give special attention to the examination of cars received at Niagara Falls during the months of July and August 1920. As a result our records covering the 30 day period ending August 19 gave the following results:

From the L. V. we received 32 cars in which shortage existed of 176 tons. From the N. Y. C., 35 cars in which shortage existed of 170 tons. From the Erie, 9 cars in which shortage existed of 27 tons. A total of 76 cars representing 373 tons short.

Figuring the value of this coal conservatively at \$14.00 per ton the loss represented \$5,222.00 during one month.

We also receive coal from the D. & H. at Rouses Point. During 1919 shortages were noted for the entire year totalling 1,795 tons. Commencing Jan. 1, 1920, a more rigid inspection was put in force and the figures covering eight months since installing this new method shows a shortage detected of 3,753 tons. To obtain the best possible results from junction inspection we are convinced it is imperative that where any depression is noted in the load or where any evidence

of leakage is evident the car or cars should be weighed as it is impossible for any examiner to give a reasonably safe estimate of the quantity missing. In fact we have had cases of shortage where the junction record showed overhead inspection made and no exceptions noted to either car or contents, yet a heavy shortage was disclosed as a result of weighing out at destination. As a result of direct enquiry to operating officials of the carrier on whose rails car originated we found the quantity claimed for, over 15 tons, was removed on their rails.

Cases of this kind of course are rare and the only inference to be derived from their occurring occasionally is that the party entrusted with the duty of inspecting cars did not in fact inspect them but merely made a book record to the effect everything was O. K.

These remarks are made not in any spirit of carping criticism but are offered in the broad spirit of betterment of the service. If they succeed in eliciting from this assembly suggestions tending to improve the claims situation or promote closer co-operation between the car inspectors and car foremen of the various roads at interest their purpose will have been achieved.

I am glad as a claim representative to meet you gentlemen. I want to say in closing that on Oriental oils we have had serious loss, and have considered the matter of preventing this loss to a large extent, but we do not seem to be getting anywhere. This oil comes in wooden barrels and in summer it seems to thin and leak. We are trying to classify it so that these cars should be iced during the summer. The shippers fought us so that we got the Interstate Commerce Commission interested.

President Gainey: I want to thank Mr. Arnold for his very instructive talk, which will be incorporated in our minutes.

W. P. Elliott: Why would oil be put in a different kind of car? The way bill would tell what that car carried previously.

E. Arnold: What I meant was, when you have to transfer a car of oil that is worth two or three dollars a gallon, try to get the same kind of a tank, and a car that is fit to hold it. On grain leakage last year the Grand Trunk paid \$128,360. There were a great many cars used that were unfit for grain. Our claims have been reduced 50 per cent the present year over 1919, notwithstanding the heavy increase in the cost of all commodities, due to the efforts of the claim prevention committee.

T. J. O'Donnell: The losses that Mr. Arnold mentions are largely due to defective hoppers. For the past five years we not only used brown paper but we used logs to keep the coal in the cars. Out of 50 cars that were delivered there were 25 fixed up with boards and stakes to hold the coal in. We cannot transfer every car that is defective. The Grand Trunk goes the limit in fixing them up. We have inaugurated an inspection in the receiving yard by a Grand Trunk man. Our car inspectors in addition to the mechanical inspection, when they are up on the end of a car to look for brake appliances, must see if there is any depression of the load. They note the depth and take a record. While I would rather see the agent do it, the car man can do it with little or no delay. It ought to be done where open top equipment is used so extensively.

I want to introduce Mr. James Coleman, who is now assistant superintendent of motive power of the Grand Trunk.

Address of Mr. Coleman

I did not expect to be called upon to say anything to you today. I came here to listen and not to be heard, and I have been very enthusiastic over what I have heard here this morning. I believe this is a school of troubles in the car department. You are starting here a campaign to show to the railroads the shortcomings in the handling of their equipment,

also in the design and construction. It is true that the equipment has not been taken care of. The railways have not had an opportunity, but if the men in charge of the departments of the railroads could only sit in here this morning and listen to the intelligent criticism, and the defects that have been brought out by you this morning, it would be an education. I want to say to you frankly that the proceedings of your meetings, if they have all been on the same strain of this one here this morning, do not get publicity enough. It does not reach the heads of the departments. You men here know more about the defects and the reasons for them than the man who sits at a desk in an office and designs the equipment and tells you how to operate it. You will find the defects.

If a man in the car department wants to find the shortcomings of some particular design of a car, who does he go to? The car inspector. He is the man who finds the defects; he is the man who knows; he is the man the railroad pays to know, and if he did not qualify he would not hold the job.

I am going to advocate, all I possibly can, more publicity for your proceedings where they will reach the men who are responsible for the maintenance of the equipment, for the good criticism that you offer here will be an education to them, as I have stated before. I am glad to welcome you here and hope you will return to Montreal next year.

President Gainey: I am sure we all appreciate the very kind words of Mr. Coleman.

W. R. McMunn: All the gentlemen who have favored us with their presence have been thanked before, but I would like to suggest that the association extend to them a rising vote of thanks, to show that we appreciate their coming. (Carried unanimously.)

Thereupon the meeting adjourned.

Wednesday Afternoon Session

At the opening of the afternoon meeting M. J. O'Connor presented a paper on the Lubrication of Freight Equipment, with regard to obtaining maximum mileage and methods to be pursued to overcome hot box trouble. This paper, with the discussion will be published in the January issue.

REPAIRING CARS IN TRAIN YARDS

BY O. E. SITTERLY

Foreman Car Inspector, Pennsylvania System

I have been requested by our secretary to open a discussion on the best means of repairing cars in train yard for defects that can so be repaired to overcome setting cars on the repair track, especially loaded with high class freight such as meat, iced commodities, poultry and similar shipments.

I personally believe that there is no one present who has not the same subject in mind, knowing the real necessity of cutting down so many cars being crippled, which have to be switched out of trains and moved to repair tracks, and bearing in mind the serious delay to shipments, the liability of claims and the extraordinary expense in so handling.

We, as supervisors, have been hiding behind the transportation department and using this as a defense, claiming that the holding up of trains to make repairs in transportation yards is causing serious delay. However, my inquiries, as well as our practice on the Pennsylvania, have proved beyond a doubt that the delay in holding cars in outside yards for making repairs has overcome considerably the delay and expense of switching cars into shops, and we find that the transportation people are co-operating with us in our efforts to cut down the shopping of all classes of cars.

It has been so arranged that on our inbound trains the yardmaster will allow us to work on trains until such time as they are ready to handle the cars, thereby we have in-

creased the number of cars repaired in the outside yard, which, as you can readily see, has decreased the number of crippled cars, delays and amount of expense in handling the cars to our shop tracks.

For your information, I am particularly referring to repairs such as brake beams, ladder treads, hand holds, adjustment of lading at doorway, applying journal bearings, etc.

I have every reason to believe that this discussion will bring out some very interesting information. Also I believe that during this discussion facts will be brought out or some recommendations made that will help us all to go back home and start a campaign in such a manner that it will be a surprise to our officials to note the large number of cars that are being repaired in the outside yards, thereby cutting down the shopping and holding up of so many cars.

It is a surprise to note the defects that cars are being shopped for at the present time. This is due to the lack of sufficient help in the outside yard. This also should be looked into with a view of reducing delays in making these repairs.

My experience in the outside yard for the past 22 years has proven to me, beyond a doubt, that there is considerable room for improvements along these lines, and I know that we have the timber amongst us today that can do considerable to help this along.

Discussion

W. P. Elliott: We do nothing in train yards except safety appliance repairs that can be made without the men going under the cars.

T. S. Cheadle: We have a man who makes repairs on perishable trains, as has been brought out in the paper. The practice is to put up a flag on the end of the train when the inspector makes his inspection and checks defects, and makes the repairs. At our Potomac yards we have a man who does not do any inspecting but passes on inspection, and makes the original record of repairs. At either yard we have a man who makes the repairs and the original record himself, and turns it in to the general car foreman to be made out on the A. R. A. billing repair card.

Mr. Smith: We have several places where we receive cars in the yard, and the inspector is not exempt from making repairs. He has to make a certain number of repairs, and then behind him comes the repair man who will make heavier repairs, such as cutting off a handhold or putting on a brake-beam. We have two men working together who follow up on heavy work. We do not exempt the inspector from making light repairs. We lock the track in addition to putting up a blue flag.

W. P. Elliott: How many follow the same practice of having inspectors make light repairs? Under the national agreement all of these men are classed as car men. The inspectors have claimed in some districts that they maintain the classification of car inspector if they do not have to make repairs. We say the car men are only entitled to the distinction that he is assigned to. It does not relieve him from any work that he is assigned to do. Do you ask car inspectors to make light repairs?

President Gainey: We ask all of our inspectors to make repairs. Three or four months ago I was at one point on our road and that subject came up, whether a car inspector had to do the work and their own inspecting. The sentiment on our system was at that point that they did. While their classification on the pay roll was inspector, it is done so that the man at the head of the department will know where his men are, but he says "A car man is a car man, no matter where he is put; if he hasn't got repairing to do he must help out with the inspecting and vice versa." That is what we are following out.

T. S. Cheadle: We are carrying that on now without any exceptions being taken to it.

W. P. Elliott: Our men say they are not supposed to do it. I maintain that a car man is a car man. If it is a question of doing autogenous welding, or something like that, it is different.

President Gainey: We take two inspectors, one light repair man and one oiler to go over a train; two inspectors go over the train and a light repair man follows. If an inspector gets to the end of the cut, he doubles back and makes the repairs until he meets the light repair man.

T. J. O'Donnell: I believe that we are overcoming the switching of light repair cars to the repair track. We have six or eight meat trains between midnight and morning. You all know what it means if you cut out five or six cars to the repair track. The D. L. & W. will hold a train while they are going through and oiling and repairing at East Buffalo. They have five or six follow-up yard repairers. I maintain that two or three men following up the inspectors on a meat train is an excellent practice, because if a meat car is set out to a repair track it not only loses the train, but the next train is 12 hours away, and when you hold it that long it means 26 or 28 hours in the terminal, because the operating department cannot handle it, and the result is that we get a claim.

R. Barnaby (D. L. & W.): In East Buffalo we have two air inspectors and two followers-up and an oiler on a train. After a train is completed by the yard department we lock both ends of the switch with a blue flag on each end. On live poultry or meat cars we apply brake shoes in the train and do all that class of work. We generally use 40 minutes or an hour on a train of 45 to 50 cars. We do everything we possibly can to keep these cars in transit.

W. P. Elliott: I believe that is the practice pretty generally to put the flag at both ends. We get a certain amount of time not only on live stock trains but on dead freight.

A. Berg: I think it is general throughout the country. I know it is mandatory with many of the railroads. We will tolerate a fellow remaining idle a few hours rather than tie up a train.

President Gainey: In some yards you cannot do that where you have 25 or 30 tracks and they are continuously switching and classifying. You can even put draft bolts in if it is an empty train.

T. J. O'Donnell: We put draft bolts in a hog train.

W. P. Elliott: You can do a lot of that work by co-operating with the yard department. In classification it is different, and if you have a car going to the repair track, it doesn't make any difference. You cannot do work on that class of trains. It is out of the question.

T. S. Cheadle: The freight houses in our territory are taken care of the same way. They have one or more men to look after the light repairs. These men are inspector and repairer and classed as such.

A Member: What is the general practice of having the material on hand for making the light repairs, and what is followed out in most yards from a safety standpoint?

T. S. Cheadle: We have a pen that we put the material in. If they have to have a brakebeam they go get one. The men go every day and fill up the pen with the pieces that are lacking in the stock that is put there. Provision is made that this can be charged out to train yard repairs.

President Gainey: In a great many yards the material is kept in about the center of the yard or some in the center and some at both ends where the men can get it readily.

A Member: At West Albany, on air brake inspection on the receiving track where there is one movement one way and another movement the other way, and also classification in the yard, we have a difficult problem. At one time we tried to test our trains on the receiving track with the engineer's valve. It was surprising to see the number of defective brakes found on the trains on receipt. We try to put in cylinder gaskets, test the triple valves and change triple

valves, and get the trains in pretty good condition on the receiving track. We had quite a big yard and found there were so many defective brakes and it delayed cars so long that we had to stop it. We tried carding and found that we needed a shop track of 5,000 cars to make the percentage and bring it up to the required 85 and over.

We have what is known as hand brake tests; one man working on top and two on the ground. These men are followed by running repair men. We have had 10 or 15 brake cylinders to take down in a train of 65 cars. I wonder if anybody else is doing that or what their method is.

R. Barnaby: We have three men on each shift. They change triples and clean cylinders on all trains after the trains are made up.

Mr. Smith: We do not do any of the work of adjusting and cleaning brakes in the receiving yard. The cars are repaired there except the brakes, and they are humped over into the classified yard. They have enough men down there and do not call the crew until they know the train is ready. All trains are made up and called one hour before they go. It does not mean that we could only despatch one train an hour; you would have to have two or three gangs, the train would be ready an hour before being called to leave.

T. S. Cheadle: I think we should all read the discussion on this by the Air Brake Association and do the best we can with it.

F. W. Trapnell: I move that the paper be received and spread upon our minutes, and a vote of thanks extended to the man who wrote it and to Mr. Barnaby who read it. (Seconded and carried.)

T. J. O'Donnell: I am going to appeal to all our members to try to get more new members. I asked Mr. Keene at noon how many he had and he said about 40. We came up here with the firm idea that we could get 150. If you brush up against anybody who is not a member, I think we ought to get after them.

Thursday Morning Session

As soon as President Gainey called the meeting to order the discussion of the selection of the place for the next convention was taken up.

T. J. O'Donnell: I really think the time has arrived when we ought to consider one central city as the meeting place of this association. We have practically covered the section east of the Mississippi River, and I would like to have our Executive Committee consider the city of Chicago as the meeting place of our association in the future.

W. J. Stoll: That city has been my choice not only now but in the past. I think Chicago should be made a permanent meeting place on account of hotel accommodations there as well as trains. The Sherman Hotel is equipped with air and electricity for power that the supply men may use for running machinery if they want to, and it would increase our membership perhaps 100 per cent.

F. W. Trapnell: I think the proper method would be to read the invitations. When I was president I favored one meeting place.

President Gainey: I am in favor of a regular meeting place, and I would like to see the members of this association this morning vote to make Chicago our permanent meeting place and let the Executive Committee set the dates of meeting. The by-laws should be changed so that one meeting place could be designated.

F. W. Trapnell: You cannot change the by-laws now.

W. J. Stoll: I believe the Executive Committee should have full power to act.

Wm. P. Elliott: I do not believe it is right to give the Executive Committee full power. They assumed power last year that did not belong to them.

T. J. O'Donnell: I move you that this assemblage recommend that this convention has come to the conclusion

that it would be for our best interests that all future gatherings of this body be held in one central city, and that the association, knowing the location and convenience, select the city of Chicago for our meetings in the future and that arrangements be made accordingly by our Executive Committee. (Seconded.)

J. C. Keene: We have a small attendance here this morning, and I think it would be well to let the Executive Committee decide.

T. S. Cheadle: It seems to me it would be no more than right to put that up to the members now.

(The question was put upon the motion and carried.)

Two papers on A. R. A. billing were then presented.

REPORT OF COMMITTEE ON A. R. A. BILLING

In order to provide the most essential requirements for A. R. A. billing, the building up of an efficient force of car inspectors and repairmen is necessary. The duties of these are to report work on cars under A. R. A. rules. The shop force, such as car foremen, car inspectors and repairmen, is the only foundation from which an efficient organization can be built, and when properly coached by some one in intimate touch with all phases of the work, the billing department will be one of the best and most efficient departments in the railroad service.

The fact that should be impressed on the shop men as well as the A. R. A. clerks is that every item of repairs should be shown on the original record, and all items should be thoroughly checked against the work performed, to see that no repairs are shown on the original record that were not actually made. This will ensure foreign lines being billed only for work actually performed, and will also ensure the handling road being reimbursed for its work.

There was, during federal control, more or less disorganization of the A. R. A. forces, which had been built up by years of training men for this class of work, and I doubt if there is a railroad in this country that is getting the efficiency they should get in the A. R. A. billing department at present. This condition results in a considerable amount of incorrect billing and causes a large amount of controversy and needless correspondence, which an efficient organization will avoid.

In our experience we have found the average shopman ready and willing to learn when an opportunity was afforded him, but, unless the importance of keeping in close touch with the rules and various changes from year to year is occasionally brought to his attention, he is liable to overlook some very important item.

The first thing that should be done when an inspector, car repairer or A. R. A. clerk is put to work, is to give him an A. R. A. book of rules to be studied. His superior should discuss the rules with him thoroughly until he is satisfied that the man is familiar not only with the rules, but that he understands their interpretation and application correctly. The A. R. A. clerk should visit the repair tracks, where the original record is compiled, as often as conditions will permit, and check the work on the car with this record, so that he may have an opportunity to familiarize himself with the work and various kinds of material used in making repairs to cars. This will enable him to check more closely the original record as turned in by the repairmen, and detect errors that might otherwise be written into the repair cards, causing them to be returned for correction, resulting in unnecessary work and delay.

For instance, if a repairman in applying a pair of steel wheels to a car would through lack of familiarity with correct billing practice fail to report the amount of service metal on wheels removed and applied, the clerk handling the repair card for the same reason would write up the repair card, leaving this information off, and forward the card to the billing department which would have to return it for proper

information, with the result that the car having gone back into service and the wheels removed disposed of, any report made would necessarily be fictitious.

Also in applying journal brasses, if the box location were omitted and the following information not given on the original record:

Coupler applied, not showing whether key or yoke attachment or size: also if A. R. A. type *D* applied not shown. Number of brake beam removed or applied.

When applying center sill or center sill splices, showing all bolts and other items necessary to complete the work: also if center sills are spliced, whether first application of splice boards, so that all bolts used will be charged at gross weight.

In applying one draft timber, if draft bolts were used other than were used in the draft timber applied, and were just shown as draft bolts, not showing how many were used in the opposite timber, would result in incorrect information.

We have just cited a few of the many, almost thousands, of discrepancies with which we have to deal almost daily.

Every effort should be made to have these reports accurate, as to fall into the practice of estimating is bound to result in fictitious information, and tends to create the impression that correct and accurate reports are not necessary, and would have the effect of introducing carelessness and indifference into clerical work, as well as loss of interest at the shops.

The report is signed by J. A. Roberts (C. & O.), chairman, and Allen Foster (N. Y. C.).

INDIVIDUAL PAPER ON A. R. A. BILLING

BY C. C. STONE
Southern Railway

The subject of the preparation of original record, billing repair cards and A. R. A. bills, is a big and important one in which all carmen are vitally interested, in that it is the only item or resource from which the motive power department of the railroads may secure a credit to their accounts and thereby reduce operating expenses, which the officials are so often called upon to explain.

The matter of records is of vast importance in supporting charges for repairs. The rules require that the original record, whether in loose leaf, card board or book form, be complete and that no information be assumed. The Arbitration Committee has always based its decisions on the records, and the A. R. A. Section III—Mechanical has gone far in the past few years in adopting standard forms with a view to obtaining uniform records in all railroads. The average mechanical man who repairs cars and also takes record of same, more or less depreciate records, and we feel that their importance should be impressed upon all concerned for the preparation of billing repair cards and A. R. A. bills, keeping in mind the principle of honesty advocated by the American Railway Association and the necessity to show the true condition at all times.

The A. R. A. rules require that billing repair cards must check with the original record of repairs, as regards the detail of charges, and that the common terms bent, broken, and missing, if used when caused by derailment, cornering or side-swiping or other causes shown in Rule 32, must qualify to show such cause, as authority for endorsing billing repair cards "No Bill."

The rules require that a billing repair card must be furnished the car owner for any repairs made to all cars. The average car department employee is under the impression that when repairs are made to a foreign car that will not be properly chargeable to the car owner, no billing repair card is to be furnished the car owner; this is entirely wrong, for the car owner desires to know at all times the repairs made and whether the repairs are proper or improper.

The preparation of original records, billing repair cards and A. R. A. bills, which involves a mass of detail work.

is largely a routine matter and we feel that the most important factor is the preparation of billing repair cards, the foundation on which the A. R. A. bills are rendered.

The car department employee should learn to term the material used in making repairs, as they are termed in the A. R. A. rules, for the benefit of employees who are not practical car repairers, whose duties are the preparation of billing repair cards.

A good deal of trouble is being experienced in not giving correct car initials, numbers and dates.

The A. R. A. rules stipulate the charges to be made for nearly all items of repairs to cars, and I would suggest to those making up billing repair cards and A. R. A. bills, that if they will keep before them the spirit or intentions of the A. R. A. rules in applying the labor charges shown in Rule 107, and which spirit or intention is shown all through the rule, it would greatly assist in eliminating if not practically doing away with the difference of opinion as to the proper method of applying such labor charges.

For this reason we wish to call your attention to the importance of an efficient organization in the car department; and to point out the duties of each as relating to this work and to show the necessity of systematic instructions in keeping all concerned thoroughly acquainted with the rules at all times.

We believe that meetings should be held upon receipt of a new rule book each year, also on receipt of supplements received from time to time, and that free exchange of views, where matters are argued from all points, is the most efficient manner in which matters of importance can be impressed upon the minds of those concerned, with a view of establishing a uniform understanding of the A. R. A. rules.

The position of car foreman is one of the most important in the operating department, and requires a man of sound judgment. He is required to repair equipment of all classes and design and maintain standards without blue print instructions. He is responsible for inspection in interchange and transportation yards and is required to pass judgment on the safety of equipment and in fact he is the versatile man of the railroad to whom all operating officials turn when anything special is anticipated. Car foremen should be thoroughly acquainted with the A. R. A. rules of interchange and billing that they will be familiar with the actual value of labor and material and thus protect the financial interests of the railroad company by which they are employed.

The position of A. R. A. billing clerk is very valuable in assisting the car foreman. The clerks should be picked from the car repair force when available, they should have a fair education and write a legible hand, and with the practical knowledge of construction of cars the task of the application of the A. R. A. rules will be much easier in the preparation of billing repair cards.

With the interchange inspector rests the responsibility of protecting the railroad company from receiving equipment with handling line defects, to see that standards are maintained, and that cars are in a safe and serviceable condition, and that no safety appliance defects exist, as required by law, and that all handling line defects are properly carded. Many interchange inspectors are located at insulated places and unless some special efforts are made to keep them posted in the application of the A. R. A. rules, they will naturally feel that their positions are of little importance and become lax. Keep the inspectors enthusiastic by calling on them occasionally, impress upon them the importance of keeping records in protecting the company's financial interests, subject them to periodical examination on the A. R. A. rules and their ability to determine proper names of various defects. Special attention should be called to the importance of showing all necessary information required by the A. R. A. rules for repairs made, on the original record and billing repair cards.

Special attention of car inspectors is called to the impor-

tance of closely inspecting all cars received from foreign lines and of requiring defect cards for all "cardable" defects discovered. It is also important that special attention be given to inspection of all cars for safety appliance penalty defects.

It not infrequently happens that an inspector, not being familiar with the A. R. A. rules, will place a defect card on a foreign car to cover an owner's defect. This is a serious mistake because under the A. R. A. rules the issuance of such a card under such circumstances makes the line issuing the card responsible for labor and material, whereas, if the card were not issued, the owner would be responsible. Great care should therefore be used by inspectors in issuing defect cards to prevent errors of this kind.

It also happens that some interchange inspectors will receive a foreign car with a handling line defect, and run the car on book record, not taking in consideration that the same car when offered at some other interchange point on the line of road will have the defects carded, thus penalizing the handling line for not having car properly carded when received at some other interchange.

Remember that a defect card is authority to bill for labor and material necessary to complete the items shown thereon and is a check against the railroad issuing same.

Defect cards should specify that all damage occurred to A or B end, right or left side, which will give bill clerk a fair conception of the damages and enable him to check overlapping labor.

The successful rendition of A. R. A. bills also requires an efficient organization thoroughly familiar with the A. R. A. rules, interpretations and arbitration decisions and in view of the importance of this work, in that they are handling the equivalent to cash money, special attention should be given to the training of bill checkers.

To successfully price billing repair cards, it is necessary that bill clerks secure a general knowledge of the physical construction of cars, which can only be obtained by practical experience or observation.

Clerks whose duties are the preparation of billing repair cards, located at or near repair tracks, who have not had practical experience, should take every opportunity to avail themselves of the physical construction of cars from observation, thus enabling them to properly prepare billing repair cards.

The handling of A. R. A. bills on the Southern Railway System is a joint arrangement between the motive power and auditing department. The motive power forces prepare the billing repair cards as to repairs made and reason for same, showing kind of material, weight of material and labor hours, the auditing force, checks the weights, labor hours, inserts all net charges and totals up repair cards, seeing that all information as required by the A. R. A. is properly shown. These repair cards are forwarded from the master mechanic's office to the auditor of disbursements' office weekly on form 1043, showing the number of repair cards forwarded. After record has been made of repair cards received, they are then passed to bill checkers for pricing. Any repair cards not properly prepared are returned to the originating station, with a notation pointing out the additional information required and calling attention to the specific rule which governs. After pricing, the repair cards are assorted as to owners and passed to the bill writers. For writing bills we use billing machines.

The auditing forces also check and voucher foreign bills; the checking is done by separate forces, one force checks and prepares bills against foreign railroads, and the other checks foreign railroad bills against the Southern Railway System. The forces are continually comparing charges, all disagreements are decided by the chief A. R. A. clerk.

The accounting department has a force of special traveling auditors, assigned to A. R. A. work. They are to visit all

shops and inspection points and confer with officers and employees having to do with making repairs to cars, and issuance of A. R. A. billing repair cards, defect cards, and trainmen's report of repairs made. Special attention is given by them to explaining and interpreting the practical application of A. R. A. rules to work done by car inspectors, and others. All officers and employees are earnestly requested to give them their hearty co-operation and support.

Their duties are both instructive and constructive, instructive in that they are required to teach the A.R.A. clerks, inspectors and repairmen the fine points of the work and explain the application of A. R. A. rules in billing, constructive in that they are required to suggest changes in methods or organization to best safeguard the company's interest.

Supplement No. 3, effective Sept. 1, 1920, on account of changes in labor hours and net material charges, and additional items, requires careful study to properly prepare billing repair cards and A. R. A. bills.

Discussion

On motion the reports were received and ordered spread upon the minutes of the association.

T. J. O'Donnell: One thought occurs to me and that is that the heavy responsibility that falls upon these accounting clerks would justify a change in their title. They should be classed as shop inspectors, or shop accountants. The word "clerk" does not appeal to me. I think also there should be an outside man working in harmony with the general foreman.

W. R. Morris (A. B. & A.): I have exclusive charge of A. R. A. billing repair cards. The greatest fault among inspectors is the different names we have given parts of repairs. If they would adhere to the rule in writing up the repairs, it would save much trouble. Some fellow will write spring bolster by three or four different names, and a lot of them are not familiar with the proper terms. I stayed five years on the repair track before I went in the office. In the past two weeks before I came to the convention I checked \$35,000 worth of bills against us. I found technical errors due to the inspector or foreman not showing conductors putting in brass and air hose. I did not write a letter because the system used on our line is to furnish all points and train crews with new brass and air hose. If the man fails to put this in, one man cannot handle it.

As for the bill clerks, I would like to have the gentlemen here go into that and tell them not to take exceptions to technical errors such as new air hose and brass applied. We are using a re-filled or re-lining brass and standard air hose and I would like to ask each of the foremen here to ask their bill clerks personally, when they take exceptions to a bill, to know that they are right and not take exceptions to a technical error that some bill clerk has overlooked.

T. S. Cheadle: It seems to me that we get the highest efficiency in this work and we should have a technical understanding of terms. It is very tedious for bill clerks. The same thing is true of sheathing on ends; on sides it is siding.

The committee appointed to consider the maintenance of passenger cars did not submit a report, but an individual paper prepared by the chairman, J. R. Schrader, was read by C. S. Adams.

PASSENGER CAR MAINTENANCE

BY J. R. SCHRADER

District General Car Foreman, New York Central

This is a very broad subject and one which requires considerable attention. After equipment is received from manufacturer, or after general shopping, it should be, and generally is, in first class condition. Therefore, it is important, in order to maintain this equipment in first class condition, that it receive careful inspection at each terminal and that all necessary repairs are made. If small defects are not re-

paired it may not be long before the car has to be cut out of service and shopped.

In order to obtain the best results there should be a system enforced at points where this class of work is done. The condition existing at each point, of course, has to govern the organization of such a system. At terminals where equipment lays over, trucks should be examined, all bolts tightened up, all worn parts which require renewing changed, brake connections and rigging keyed and bolted and cars inspected in general on the exterior and the interior for any defects, and proper repairs made.

Lubrication being one of the important items, journal box packing, brasses and wedges should be examined on arrival at terminals and given proper attention. Good results can be obtained by having a book of instructions for the lubrication and care of journal boxes.

The axle lighting system should receive careful inspection and proper repairs, and also be governed by a book of instructions for the maintenance of electric car lighting equipment.

Air Brake Maintenance

At terminals and repair tracks proper inspection must be made, and this can only be done by the use of a testing outfit, either stationary or on a truck. As the application and release of brakes are the two most important factors, it is essential that the rate of brake pipe reduction (to apply) and the rate of increase of brake pipe pressure (to release) be made as near as possible to actual operating conditions in order to determine that equipment will operate in a satisfactory manner when the car is placed in any location in a train, and the above cannot be accomplished if a too rapid reduction, or increase, is made. As for instance, the use of the angle cock, to apply, and the opening of the angle cock to which a yard hose is attached, for release, should not be considered as a test for the reasons given above.

At shops and repair tracks when triple and control valves are removed for cleaning and repairs, special attention should be given dirt collectors and strainers, as they perform an important part in keeping foreign matter from the valve mechanism.

The automatic slack adjuster when cleaned should be tested for leakage both in the piping and its cylinder. The brake cylinder piston travel should be let out beyond eight inches to ascertain if the adjuster is in proper working order. Oil or grease should not be used on the slack adjuster screw.

On cars equipped with P. C. equipment and automatic slack adjusters it is not only important that the travel of both the service and emergency brake cylinders be adjusted equal but it is also necessary to know that the service cylinder adjuster is in operating condition; as inoperation of this adjuster is very likely to result in tight brakes.

When brake cylinders are cleaned, a wooden paddle, the edges of which have been rounded, should be used in placing the packing leather in place in the cylinder. Many packing leathers are ruined by using chisels, or such tools as file shanks, or iron scrapers. The amount of lubricant used should be measured for each size of cylinder, not guessed at. The exact quantity of lubricant should be determined by a set of tin measures furnished, each measure stamped so the cleaner can know the proper amount allowed for each cylinder. An excessive amount of lubricant in brake cylinders is not only wasteful, but is liable to be forced into the triple valve mechanism, thus causing improper operation of the brakes.

The work mentioned above should only be done where proper air pressure is available, for to make repairs without making proper tests after equipment is applied to the car is out of the question.

All triple and control valves when cleaned should pass the prescribed tests for such valves before they are allowed in

service. This should also apply to new valves received as spares or on new cars.

The tests can best be made and better results had if valves are not lubricated before being tested, as in this manner worn bushings and poorly fitting packing rings can be detected; while, if lubricant is used, especially heavy oil or grease, the valve may pass the test O. K. and in a very short time fail in service. As the cost of cleaning and testing air brake equipment is no small item at the present time, we cannot be too particular in regard to the kind of repairs and efficiency of tests made in the air brake room. I might also add that past experience with lubrication of triple and control valves shows that the less used the better results will be had. Only dry graphite should be used on the slide valves and seats and then the quantity allowed to remain on the parts should be so small that it cannot be seen.

The improved method of testing triple and control valves devised by the Westinghouse Air Brake Company will give better results and all older types of test racks should be modified to the new, as the new method of testing for packing ring leakage and friction is far above the old.

The question of removing equipment from the car and sending to the air brake room for testing and cleaning on account of slid flat wheels, in the majority of cases is unnecessary, as the equipment can be properly tested by the use of a yard test truck, and when any equipment fails to pass such test it should be removed.

Weather and track conditions are responsible for more slid flat wheels than defective air brake equipment.

Car should receive proper cleaning on arrival at terminals and should be handled in a systematic manner and the interior as well as the exterior of the car should be well cleaned. The best result from this cleaning can be obtained by instructions on the proper method of cleaning cars at terminals, these instructions going into all details such as, general cleaning, interior cleaning, exterior cleaning and economy in material, and the workmen should be governed by the book instructions on cleaning.

Roofs of cars should receive regular inspection and be repainted when found necessary; floors, platforms and steps, and all iron work which has become rusted should receive same attention.

Shopping of Cars for General Repairs

General repairs to a passenger car is divided into three classes of repairs, viz.: A, B and C, which class of repairs denotes the paint operations only, and are explained as follows:—

Class A repairs covers the removal of all paint and varnish from the exterior of a wood car by burning, and a steel car by sand blasting, or when all sheathing or plates have been renewed.

Class B repairs covers the removal of all paint and varnish where necessary on a wood car exterior, painting the car complete, re-lettering and numbering.

Class C repairs covers the painting of the exterior, cutting around lettering and numbers, thus eliminating the additional expense of re-lettering and numbering.

When a passenger car arrives at the shops for general overhauling it follows the routine as designated.

1. *Inspection and Classification of Repairs.*—The receiving Inspector keeps a record of all cars arriving at the shop, and makes a daily report to the superintendent of shops. He records the number of the car, class, type, lighting, and any noticeable or carded defects. If the car is in a condition for general repairs, he shops the car for classified repairs, A, B, or C, noting any additions or betterments required. A "Bulletin Board," in the inspector's office, is maintained, showing the cars shopped daily.

2. *Stripping the Car.*—The foreman of the strippers notes the cars shopped daily and operations are started wherever the

car is located in the yard. The stripped cars are spotted, and delivered to the wash shop via electric transfer table. All material is removed from the car and delivered to the various repair departments for cleaning, inspection and repairs.

3. *Wash Shop Work.*—When all material has been removed from the car, the interior is scrubbed, pipes scraped, if necessary, and the exterior is burned off or washed according to the class of repairs. Steel cars for sand blasting are delivered direct to the sand blasting room prior to entry in the wash shop.

4. *Repair Shop Work.*—When the car has been finished in the wash shop, it is then delivered to the repair shop, jacked up, placed on horses and the trucks removed for their repairs. After the car has been jacked up and trucks are removed, the car is given a careful inspection, defects noted and card attached to car, showing repairs, changes, etc., to be made.

During the course of repairs, the air, steam and water are tested and repairs made. Roofs are examined and repaired. Electrical work on car is also repaired. New wood applied, or plates renewed, is primed while the car is in the repair shops, thus saving time on the arrival of the car in the paint shop.

A bulletin board is maintained in the repair shop showing date in shop and date the car is due to be delivered to the paint shop, also all other parts removed by the strippers must move forward to the painters on the same day the car is delivered.

5. *Car Delivered to Paint Shop.*—When the car arrives in the paint shop, the car is inspected and a delivery date is forwarded to the delivering inspector, who makes a daily report, of cars to be delivered, to the superintendent of shops, who, in turn, notifies the superintendent of passenger transportation, when the car will be ready for service.

A bulletin board is maintained in the paint shop showing the dates cars will be ready for trimming, and all material removed must be ready for application.

When the painters have completed their work, the car is turned over to the trimming department, who trim the cars before they leave the paint shop.

6. *Final Inspection.*—The car is then taken out of the paint shop, placed on scales, weighed, measured for height and is then placed on the inspection and testing track.

Air, steam, water and electrical systems are tested, and the brakes and car adjusted. Final inspection is then made by the delivery inspector, and when all adjustments have been made the transportation department is notified that the car is O. K. for service.

(On motion the paper was received and ordered spread upon the minutes.)

A paper on the subject of lubrication by J. C. Stewart, foreman freight car inspectors, Cincinnati, Indianapolis & Western, was then read.

LUBRICATION REQUIRES ATTENTION

BY J. C. STEWART (C. I. & W.)

While I know that the interchange rules and car department work and duties will, as usual, be ably and efficiently discussed and handled from every angle during this convention, I have one great handicap in particular in mind, namely, hot boxes. I desire to suggest that the association arrange some means of urging and encouraging all the railroads to start a "more efficient understanding and service drive" along the lines of the care of the journal box.

We know that hot boxes are always caused by excessive friction, and that a vast amount of instruction as to the best method of handling lubrication, etc., has been issued from time to time. Notwithstanding this there still remains a great deal to be done before conditions will be as good as desired. While I am not in a position to state, neither do I

believe, that there is lack of efficient service in this line on all railroads; however, I do know that the majority of railroads have cars running throughout the country with such equipment in poor condition.

In many cases we find car oilers, box packers and even car inspectors who do not have the proper knowledge of the many causes of hot boxes, which cause a multitude of troubles and costs. All these troubles are caused by two conditions; either defective lubrication or excessive bearing pressure. However, we are aware that there are many details connected with the insufficient lubrication or excessive bearing pressure area, and, in order to get the proper results, all employees should know how and why they are caused. Unless they are familiarized with and we remedy these causes, we cannot successfully attempt to overcome or remove them.

Apparently, in many cases, authorities do not act in close enough relationship with these matters, thereby not following up and urging better conditions and attention. As, for instance: sending employees out along the divisions daily to repair hot boxes on cars set out of trains, and not keeping a record and check of the causes, etc.

There are many causes for the hot box situation that can be made readily remedial. I believe that the association through the officers or a committee could, by going in detail and following up these conditions, advocating better service to all railroads through correspondence, do a great service. I feel all officials and supervisors will consider that our best and most consistent friends are those who tell us of our faults, and they will thereby impress upon the minds of employees that if we want knowledge, like anything else, we must toil for it, and that the price of success in any line is not too great to pay. For the fit man, with no apology up his sleeve, is always admired.

On motion duly carried both papers were received and the subject carried over for next year, with the suggestion that a paper be prepared by M. J. O'Connor and the same committee continued. F. W. Trapnell then read the report on uniform inspection blanks.

REPORT OF COMMITTEE ON UNIFORM INSPECTION BLANKS

This committee was appointed at the annual meeting of the association held at St. Louis to look into the matter of a

and the record of the car entirely lost. After considering the various forms submitted the chairman of the committee with A. Kipp recommend that the blank form shown herewith as Fig. 1 be used for points where the inspector merely takes the physical or mechanical conditions of the car, but at points

A. B. C. RAILROAD

DAILY REPORT OF CARS INSPECTED

TimeDate19....

FromTo

Fig. 1—Form for Recording Physical Condition of Cars

where the inspectors, working under a bureau, take the records for the transportation department in addition to the mechanical department, we recommend that the form shown in Fig. 2 be used.

The card for bad order safety appliances, should be print-

Fig. 3—Card for Bad Order Safety Appliances

ed on both sides as in Fig. 3, showing on one side where safety appliances have penalty defects and must go to the repair track for repairs and the other side showing safety

uniform inspection blank to be recommended to the Arbitration Committee of Mechanical Section III for their consideration and adoption, if in the opinion of this committee it would be necessary.

I have written all the interchange points of any particular note and secured samples that were being used at various points. We find all kinds of forms and some points with merely a book record. The book could easily be misplaced

appliances with penalty defects but light repairs that can be made in the yards by the light repair men.

The committee is in receipt of a communication from T. J. O'Donnell, stating that at Buffalo there are two lines only having a form for handling their cars in interchange, the balance using a book.

Those are the only two members of the committee that I have heard from but I would recommend that the matter be

discussed and if in the opinion of the association such blanks should be recommended to the A. R. A., I believe that we will be making a move in the right direction as the Mechanical Section III from time to time has been simplifying and getting uniform rules and regulations, uniform cards for handling the business and a uniform blank would be not out of place so that the records could always be taken care of at a very little expense, a great deal less expense than by using a book record.

Discussion

After reading the report Mr. Trapnell said: The need for a uniform inspection blank was brought out by a freight claim agent of the Canadian Pacific who stated that without a proper record of a car at the initial loading point, the road loading the car would have to assume all of the responsibility for loss to that car. I have before me the blanks of the various interchange points throughout the country and I find that they are badly mixed up. Some have none; some have a blank piece of paper, without any heading, to be torn out of a book. These are easily misplaced unless a file is provided to keep them in.

The chairman of the committee corresponded with each point and after assembling the blanks and picking out the various kinds, each member of the committee having a copy of the blanks used by other points, the chairman took it up with all members, recommending a certain blank. I have a favorable reply from one member of the committee, Mr. O'Donnell, but he does not give his sanction of a uniform blank.

(A motion was made that the report be accepted and the matter referred to the Executive Committee for their handling at the February meeting and report at the next meeting.)

T. J. O'Donnell: My recommendation was on personal talks of our 150 car inspectors. They seem to all favor the book in bad weather. If you make out a blank statement today and file it in the office of the chief interchange inspector or a foreman is there any reason why an inspector, if he wants to make a false record, cannot get that blank and replace it with another blank? You fill the book from beginning to end. All you can do with that is simply to erase it. That was my reason for not voting affirmatively for the blanks. It seems to me, if you have the books properly filed, they will serve the purpose much better than the blanks.

W. J. Stoll: The form that is being used in our city is sent in by the inspector at the end of the day. One copy is filed in the chief interchange office and a copy of it is kept in his possession, or in the possession of the general foreman for him. The hard copy is sent to the interchange office and no inspector or anybody else can get in there without a key.

F. W. Trapnell: We use a blank and the inspector makes five copies of that inspection: one for the receiving line, one for the delivery line, one for the receiving agent, one for the delivering agent and one for the I. C. C. In that way we save an enormous lot of work by furnishing the agent the physical condition of the car when it is received, and when he gets his claim back he has the condition of that car.

T. J. O'Donnell: I favor the agent having a record. It saves a lot of correspondence. It would overcome 3,000 claims a month coming to our office.

President Gainey: We do the same as Mr. Trapnell, except that we do not give the agent a copy. The inspector takes the numbers and initials of the cars in his book. On those that are defective he notes the defects. After going through the cut, he takes the record to the shanty and writes three copies on a form: one to the delivering line, one to the foreman of the receiving line and one to the I. C. C. His own record is his book record.

W. M. Herring: We tried to get up some kind of a sheet instead of the five by nine book. Some claim they can carry

a book in their pocket much handier than the sheet. We continued the book on account of the objections to carbon, and the disadvantage of carrying our sheets either in pad form or any other form.

President Gainey: That has been the general objection. Kansas City is about the only one that has used the loose leaf form.

M. W. Halbert: We tried the book record several years ago and now we use the sheet. The inspector writes the original record and takes a copy. The original he sends to the chief inspector's office, and the duplicate is sent to the foreman of the delivering line. We never have any trouble.

W. P. Elliott: In our district we take two and three copies of the record. I do not approve of making six copies of the record. Mr. O'Donnell is right; to put carbon in between four sheets of paper in rain or snow you have a job. I approve the loose leaf idea. It gives a better filing system in the office. I do not think it is a good idea from a practical standpoint to furnish the agent a copy of that record, because they have all of these records in their own office and I am satisfied there is less expense when we furnish them than in furnishing to all of the agents. If you put another man in the office it would be cheaper if you figure the time the inspector consumes in doing this extra work.

E. H. Mattingley: I want to agree with what Mr. Elliott has said. I think the car inspector today has all he can do without making five carbon copies of his records as to the condition of a car in interchange. If he will carry out the inspection according to the rules, take care of running repairs on defect cards, he has about all any man wants to do. We have joint bureaus at the large terminals and they get the original record at the time the car is inspected. If anybody else wants it, why not get it from that office?

F. W. Trapnell: I did not recommend that in the report. I simply said we did that. I do not care how many copies you have, but the idea that Mr. Mattingley laid down is not a correct one to place before this convention. The inspector makes five records with one scratch of the pencil. The car inspector is not so loaded down with work. The carbon is changed in the twinkling of an eye.

W. P. Elliott: I agree with Mr. Mattingley and disagree with Mr. Trapnell. The most disagreeable thing a car inspector has to do today is to change the carbon. I know whereof I speak. Many a time I have written my records on a bad night and found that I had the carbon upside down.

T. S. Cheadle: I know from experience that the form as recommended by Mr. Trapnell can be used, for so far as the use of carbon, if a man wants to do a good job he can come pretty close to doing it, and if he wants to make a bad one he can do it. As I understand it, Mr. Trapnell is not recommending his way.

A. A. Helwig: It does away with much correspondence with the agent. Where we get 10 or 15 claims from the agent, it means taking down back records. At Kansas City they let the agent do it himself.

W. J. Stoll: Our system has been in force since 1910 and the trouble with it from the agent amounts to nothing. The records are so handy that in a very few minutes we can dig up records of five years back.

E. R. Campbell: We are using the type of blank furnished by Mr. Trapnell. We only make three copies, one copy for the chief inspector's office, one for the inspector on interchange and one goes to the Western Weighing Association, which has a bill of lading over all the roads.

E. H. Mattingley: I do not want Mr. Trapnell to understand that I am taking exceptions to his form, but I do object from practical experience in trying to insist on a car inspector making three or four copies at the time he inspects his car.

President Gainey: One of the finest records I ever saw in a chief interchange inspector's office was in Mr. Stoll's

office at Toledo. I could pick out anything in 5 to 10 minutes. I do not approve of making four or five of these copies, as suggested by Mr. Trapnell, but I do believe in a regular form. The inspector takes his record in a book of the entire cut, and makes a report to the delivering line, the foreman of the receiving line and one to the chief joint inspector, keeping the book record. If the claim agent wants to know anything about that car and can give the date received the inspector will give him the defects in less than five minutes. We ought to have a regular form, but like the others, I do not think an inspector should be required to make four or five copies in the yard.

F. W. Trapnell: That isn't part of my recommendation. The only recommendation is that we have a uniform blank.

M. W. Halbert: We have used a form 3½ in. by 9 in. for 10 years. The inspector uses one piece of carbon and takes two copies. We have a pigeonhole just the size of these slips. We have 24 railroads and 100 connections from which we receive these daily reports. All cars received by each line are separated. All cars delivered by the same line are kept separate. All we have to do is to go right to the pigeonhole. We can get a record in two minutes of every car that is handled. The reason we made the form that size is that it fits the inspector's pocket. We have no trouble whatever. It is a nice clean proposition for the inspector and everybody else.

A. Kipp: I was one of the committee and it does not seem to me that we are getting anywhere, or that this body could do anything more than make a recommendation that this blank be a standard blank to be used throughout the country for making records, and until such time as that is approved by the A. R. A. we have no authority to say that it shall be used. We can go on and keep just such records as we see fit, and if we do not agree to use this blank we can use a book. It seems to me with all this discussion this association should do one thing or another, accept this committee's report and recommend a blank, or to reject it.

W. M. Herring: In the southeast we cannot require an inspector to furnish a record to the transportation department. Any information they get, must be obtained from the mechanical or car department. (The motion for the adoption of the report was put and carried.)

Secretary-Treasurer's Report

The Auditing Committee reported that the books of the secretary-treasurer had been audited and found correct.

REPORT OF SECRETARY-TREASURER.

Members deceased during the year— C. D. Mitten, St. Paul, Minn.	

Election of Officers

The following officers were elected by unanimous vote:

President, Edward Pendleton, general foreman, Chicago & Alton, Chicago; first vice-president, A. Armstrong, chief interchange inspector, Atlanta, Ga.; second vice-president, W. T. Westall, special inspector, New York Central, Cleveland, Ohio; secretary, W. P. Elliott, general car foreman, Terminal Railroad Association of St. Louis, East St. Louis, Ill. Members of Executive Committee (to fill vacancies): W. H. Sherman, car foreman, Grand Trunk, Sarnia, Ontario; A. Herbster, assistant master car builder, New York Central, Chicago.

Other Business

At the Thursday morning session, the arrangement made for publishing the official proceedings of the convention in the *Railway Mechanical Engineer* was ratified and the matter was left to the Executive Committee for further action next year.

The entertainment provided by the Supply Men's Association during the meeting included a trip to the top of Mt. Royal; an informal reception and ball; a tea party; a theatre party; and a sight-seeing trip around the city of Montreal.

The resolutions committee, T. J. O'Donnell, chairman, reported as follows: The members of the Chief Interchange Inspectors and Car Foremen's Association of America in closing their twentieth annual convention in the city of Montreal, Quebec, wish to repledge and offer our fullest individual and mutual support to the mechanical and car department officials throughout the country for the purpose of bringing about the very best and most efficient service that the public and higher executives demand or hope to carry on in the future, realizing the efforts and labor required from each and every one in railroad service to bring such results about.

The Chief Interchange Car Inspectors and Car Foremen desire to express their united appreciation and sincere thanks in closing this annual gathering in Montreal to the following who have contributed to the success of this meeting and the pleasure of the guests while in this City:

First, to the City of Montreal, including the press, and the officers of law on the street, for their uniform courtesies.

To the Hotel Windsor for their excellent service and permission to many of our members to sit up all night in their lobby. (Applause.)

To the beloved and loyal gentlemen of the Supply and Entertainment Committee for their indefatigable and unceasing efforts at this convention, as in many of the past, to make our stay and convention such a pleasant and grand success.

To the railway officials in this district, particularly James Coleman, of the Grand Trunk, to E. Arnold, of the Grand Trunk, to J. E. Grant and T. O'Donnell for their inspiring talks and valuable suggestions for the guidance of this association, as well as to the officials of the Canadian Pacific and other railways for their attendance and interest in our numerous gatherings, and help in making our stay most pleasant and return to our homes most agreeable.

To our presiding officer, J. J. Gainey from Ludlow, Kentucky, we tender our heartfelt thanks. While we have known his genial and pleasant disposition in the past, we have gladly recognized it in the highest position of our association, that of presiding officer.

To our secretary Mr. Keene, who leaves us after one year of service, we extend our sincere thanks for his efficient service. We are very grateful to Miss Unkenholz for her courtesy as our stenographer. And to all the people in Montreal who have contributed toward our pleasure while we have sojourned here, we are deeply indebted.

May we return to our homes full of hope, and may future gatherings, wherever they may be held, be as pleasant and splendid as this great convention has been in Montreal.

The convention closed with the singing of the national anthem of the United States.

CANADIAN PACIFIC HOPPER BOTTOM BOX CARS

High Ratio of Load to Gross Weight in New Equipment Designed Especially for Grain Service

TWO features which make the equipment particularly suitable for service on a road with a heavy grain traffic stand out strongly in the design of the latest box cars recently placed in service by the Canadian Pacific. The limit load which the cars will carry is $60\frac{1}{2}$ tons and the floors of the cars have special hopper bottoms which are designed to facilitate unloading of bulk material and to eliminate the need for temporary grain doors. Roads that have a heavy merchandise traffic generally consider that the cubical capacity usually limits the load in a box car and, therefore, a 40-foot car with a limit load of about 45 tons is most economical. However, where much grain and coal are carried in box cars, as is the case on the Canadian Pacific, the extra cost of the heavier car is, no doubt, more than offset by the higher ratio of load to total weight in a fully loaded 60-ton car. In these cars, which are 40 ft. 6 in. long,

door posts, pressed steel intermediate posts and braces and to the flanges of the corrugated steel ends. Pressed steel posts and braces were chosen in preference to rolled sections because the ends have area for riveting without the use of gusset plates, and the ends of the braces can be brought much closer to the ends of the posts; also the pressed shapes provide superior support for the sheathing boards. The ends of the car are of pressed steel, each end being in two sections.

The roof is of the flexible outside metal type supported on metal carlines. All carline flanges are covered with strips of wood arranged to prevent the accumulation of dust that might be shaken down from time to time and possibly damage the lading.

Grain Hoppers

Hoppers of the Burnett type are located at the side door

Box Car With Burnett Hoppers Built for the Canadian Pacific

8 ft. 6 in. wide and 9 ft. high inside, the ratio of load to gross weight is 71.4 per cent.

Type of Construction

The cars are built with steel underframes, steel side frames, corrugated steel ends and outside metal roofs. The center sills consist of two 12-in. channels continuous from end to end of the car. The bolsters and cross bearers consist of pressed steel diaphragms with top and bottom cover plates, while the floor beams are pressed steel diaphragms. The decking, which is $2\frac{1}{4}$ in. thick, is secured directly to the center and side sill flanges by means of bolts.

The side frame consists of 9-in. channel sills, 6 in. by $3\frac{1}{2}$ in. by $\frac{3}{8}$ in. angle plates, 4-in. Z-bar door posts and U-shaped pressed steel posts and braces. The side sheathing, which is $1\frac{1}{2}$ in. thick, is bolted to the flanges of the

opening on each side of the car. When used for freight that cannot be dumped through the hopper the car has a solid level floor, the same as an ordinary box car; when grain, coal, etc., are to be loaded the specially constructed sections of floor over the hoppers are turned up against the side door post. This arrangement allows the load to go directly into the hoppers, and also saves considerable temporary door lumber. When the cars are unloaded it is only necessary to remove the pin that locks the hopper doors; the doors open quickly by gravity and immediately a large percentage of the contents of the car discharges through the hoppers. The balance of the load may be shoveled to the middle of the car by hand, or if the unloading plant is equipped with power shovels, as most elevators are to-day, the floor door on one side of the car is released from the door post and the cables are taken through the door opening as usual. The

hopper doors have no operating mechanism, the doors being closed directly by hand and secured by a simple locking bar arrangement.

Special care has been taken to obtain a side door of satisfactory design. The interlocking front and back edges afford exceptional protection against weather and pilfering. The top edge is thoroughly weatherproof, yet so arranged that it cannot become blocked with ice. The bottom of the door is fitted with turned rollers that fit on a very substan-

The Hopper When Open Discharges Outside the Track

tial and rigidly supported track. This track is not likely to be blocked with ice but in case it should be the interference is plainly visible and easily removed. The location of the rollers at the bottom of the door does away with the binding or cramping so frequently noticed on doors suspended from the top.

The brake arrangement includes a manually operated

Interior of Car With Hoppers Closed

slack adjuster, which is a double safety device, as it enables inspectors to adjust the brakes to compensate for wear on brakeshoes without going under the trucks; and, as no truck parts are disconnected, the possibility of trouble due to oversight in replacing connection pins is eliminated. As the time required to adjust the brakes by this device is much less than with the old arrangement it enables inspectors to

give attention to more cars in a given time, thus resulting in better maintenance and less detention. The hand brake arrangement is specially designed to be operative regardless of climatic conditions, this being accomplished by arranging the ratchet, pawl, etc., so that snow or ice on top of the

Floor Section Raised for Grain Loading

parts will not interfere with their operation. The entire arrangement is located overhanging the end of the roof so that it is impossible for even the deepest snow to pile up underneath. The ratchet pawl is of the gravity type, and therefore the trainman is not required to use his feet for holding the pawl in position.

The trucks are of the standard arch bar type with improved truck columns, spring plank and truck column fastenings, pinless brake beam hanger brackets, and four-point brake beam suspension. The railroad states that up to date this type of truck has given the best satisfaction in Canada.

THE SUCCESSFUL FOREMAN*

BY W. P. ELLIOTT

General Foreman, T. R. R. A. of St. Louis

To my mind a successful foreman possesses two very important qualifications. One is loyalty, and the other is ability, which, of course, covers a very broad scope. It has been said that an ounce of loyalty is worth a pound of cleverness. I have often thought in my contact with men and in the daily performance of my duty how necessary loyalty was to success. Be a man ever so clever, without loyalty to the company or individual he is working for, his cleverness or ability is liable to be more detrimental than beneficial.

During the period of federal control I visited nearly every car shop and repair shop in the St. Louis and East St. Louis terminal. During that time the salary of a car foreman was hardly in proportion to the ability and responsibility expected. That has, in a large measure, been rectified since that time. However, I could not help noticing the attitude of some of the men filling supervisory positions. Regardless of the wage conditions or the working conditions under which foremen were working at that time, there was hardly any excuse for the attitude of some of them. The dissatisfaction was so apparent that it had its effect on the men that were working under the foreman. That "don't care" spirit went out to the men they were expected to lead, and the result was about what was to be expected.

I think one of the best characteristics of a foreman should be his ability to overcome difficulties, personal difficulties as

*From an address delivered before the St. Louis Car Foremen's Association

well as difficulties that come up in his daily work. If the foreman would be successful, it is essential that he be considered as to his capacity for accepting responsibility and his capacity for leadership. I do not know exactly what to attribute the lack of acceptance of responsibility to, unless it is due to labor organization. It seems that labor organizations have caused men, rather than leaning on their own responsibility, to lean on some organization or some set of men. For a man to be successful in a supervisory capacity, he should lean entirely on his own resources. Within the past two years especially there has been a disposition for men to say, "Why should I want the responsibility? Why should I take the leadership." And to my mind those men are not successful foremen.

When a foreman is given charge of a plant, regardless of its size, he should feel the responsibility of the management of that plant, and he stands in identically the same relation toward his superior as the general manager stands toward the corporation. He should be keenly interested in the success of that plant, and he should be keenly interested in the economical operation and should feel the same responsibility regarding its management that he would feel if it was his own individual property.

The car foreman today has an exceedingly responsible position. As an example let me cite the hazardous and highly perishable commodities now handled in tank cars. Few foremen realize the responsibility connected with the handling of this class of equipment. The tank car itself is relatively simple, but the commodities it carries makes exceptionally intelligent handling necessary. I have found that the simplest of defects have been considered serious by many car foremen and inspectors and many of the more serious defects have been considered simple. This has been due to lack of knowledge of the cars and their commodities. A foreman should know the United States Safety Appliance laws, and he should know well the rules of the Mechanical Division of the American Railway Association, and he should subscribe for books and periodicals that deal with the car department.

There are very few periodicals at the present time that go into car department matters very thoroughly. However, the car man himself is as much responsible as the publisher, if not more so. Publishers are always glad to receive subject matter from men who are on the ground, but car department matters have been principally covered by mechanical engineers, bill clerks, master mechanics and others who would be less liable to understand real car conditions and methods than the car man.

One of the features in being successful is to properly spread abroad your ideas so that other car men will have a chance to criticize them, either favorably or unfavorably. To my mind there is no other one thing that so broadens a man as association and discussion of the problems that confront us in our daily activities. I would like to see the car foremen get the habit of reading articles and talking upon matters that concern our daily duties.

For instance, as an idea for a subject, how far have we gone into the question of economical lubrication? What ideas have any individual car men put out as to the preservation of cars by painting? What ideas have we put forth or what action have we taken towards the proper inspection and the maintenance of draft gears, and what system of repairs have we suggested for draft gear, which is very essential to the proper handling of freight cars today? I recall very few papers that have been written on the question of brake beam failures, and yet there is no other one thing that is as important to us today. I think it would be a good thing for you, a good thing for the association and for car men in general, if there was more written on these subjects and more discussion of them by practical car men.

There is much that could be said that would be of assist-

ance to car men towards success, but the things that come most forcibly to my mind are: be loyal, respect your superior and if there is any shortcoming, see that he knows about it, and I am sure that you will be given proper consideration. Invite responsibility. If there is any one thing that will make for success, it is that. Everyone admires a man who invites responsibility, and it gets back to the old saying that a man who does not make a mistake is not a real man. When you invite responsibility, you invite mistakes, and when you invite mistakes, you are showing your superiors that you are at least progressing.

SIMPLE DEVICE AIDS IN CHANGING CAR JOURNAL BRASSES

BY ROBERT I. LILLIE

All car shop employees, especially those responsible for work on the rip track, realize the difficulty that often is met in changing brasses or making other repairs to journal box parts. It is necessary to use a jack to lift the box from the journal and many times the wheel raises at the same time and has to be driven back by hammers or wedges between the wheel and the car body.

To obviate this difficulty a simple arrangement, illustrated, has been devised. An old brake beam lever is bent as indicated and placed with one end resting on a block, the

Efficient Arrangement for Jacking Up Journal Box

other offset end being supported on the inside rim of the wheel. When a jack is applied between the brake lever and bottom of the journal box, it is evident that operation of the jack will cause the journal box to lift, the wheel being held down by one end of the brake lever.

By placing the jack a little nearer the rail than shown in the illustration, there will be even less tendency for the wheel to lift. This device is sometimes called a wheel holder. When made from scrap truck levers it is inexpensive to make and its use results in a considerable saving of time and labor in making journal box repairs.

LINING DRIVING BOX SHOES AND WEDGES

A Shoe and Wedge Lay-Out Which Involves Little Possibility of Error; Pedestal Jaw Grinding Machine

BY J. McALLISTER

General Foreman, West Albany Shops, New York Central

ONE important object in laying out shoes and wedges is to place driving wheels under the locomotives so that the tire flanges will not cut or wear more on one side than on the other. That this object is not always attained with the usual method of laying out shoes and wedges is evident from the large amount of flange cutting which is found in practically all locomotive shops. It is a common occurrence, after a locomotive has received general repairs to see on the work report, "Throw wheels on account of flanges cutting."

Years ago when locomotives were small and parts light and easy to handle, a sharp flange was not so serious a matter as at present when motive power is relatively heavy. At the

to fit the standard contour of a tire flange. A movable or sliding scale, graduated as shown, is arranged to be clamped in any desired position by means of a thumb screw. The method of using this gage is plainly shown in Fig. 2 and consists in measuring accurately, at the two positions shown, the distance between the working side of the flange and the frame. The theory was that if these distances proved to be equal, the flange must be parallel to the locomotive frame and

Fig. 1—Gage for Measuring Distance Between Tire Flange and Locomotive Frame

present time a flange which shows signs of cutting is often neglected until it becomes so bad that the wheels must be dropped and tires changed, or the locomotive sent to the shop for tire turning. The result is a low mileage and high cost of maintenance.

The method usually employed in laying out shoes and wedges is to work from the centers of the cylinders, trammings back to the frame jaws. There really is no good reason for working from the cylinders, however, as the only connection between them and the wheels is the main rods, and they must be adjusted to equalize piston clearance. With this fact in mind and with a view to getting data which would demonstrate the value of the proposed new method of laying out shoes and wedges, the gage shown in Fig. 1 was made. This gage consists of a piece of 3/32 in. steel shaped as indicated

Fig. 2—Method of Using Gage

would not, therefore, cut or wear away faster than the flange on the opposite wheel.

Several precautions had to be observed in the use of the gage. It could be used in the case of turned tires only because of the possibility that new tires might not be shrunk on in exactly the right place. It was found necessary to check only the main wheels, the other wheels being trammed from the centers of the main wheels. In taking measurements with the gage, two points were selected on the front and back of

the wheel on a line parallel with the top of the frame. This is illustrated in Fig. 2.

All locomotives coming to the shop for a certain period were tested with the gage previously described, and it was found that when the wheels were parallel with the frame, all flanges were worn evenly; when not parallel, they were cut on one side or the other. The practice was then adopted of gaging the wheels in the shop after the locomotive had been wheeled, the shoes, wedges and binders put in place on the main jaws and the wedges set up tight. When the gage showed that the flanges were not parallel with the frame, the

method of laying out is explained, the jigs and gages being described in the order in which they are used.

After locomotives are stripped in the erecting shop and necessary bolting done, the frame jaws are inspected by the erecting shop foreman in charge. If the jaws are found to be worn, they are trued up with the grinding machine illus-

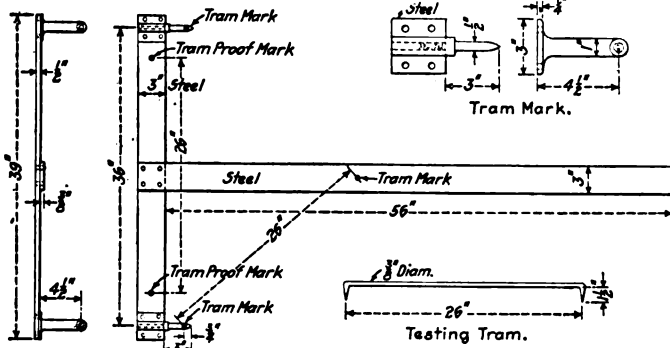

Fig. 3—T-Square for Laying Out Shoes and Wedges

binders were pulled down and the shoes and wedges relined to correct the error.

The results of the above practice were in a way surprising. No matter how carefully the laying out was done, it was found necessary to throw the wheels more or less on about 60 per cent of the locomotives. The improvement in flange cutting which followed was so pronounced that the extra work entailed in throwing the wheels was felt to be well worth while. Practically doing the work twice, however, was expensive and the attempt was made to find a better method of laying out shoes and wedges.

Method of Laying Out

Having proved conclusively that flange cutting on one side of a locomotive could be eliminated if the work was done

Fig. 5—Gage Used in Setting Tool for Planing Boxes

trated and described later on in this article. This machine does accurate work, saves the labor of filing and removes just enough metal to true up the surface of the jaw.

Referring to the lay-out shown in Fig. 4, the box center is

Fig. 4—Method of Laying Out Shoes and Wedges

properly and checked with the gage, it was decided to standardize the work and develop a set of jigs and gages which would reduce the possibility of errors to a minimum. The

located on the main jaw and a vertical line drawn through the center, using a small square. The T-square, illustrated in Fig. 3, is now brought into use. This is not a plain T-

square, but has two projecting points raised a set distance above the square, an arrangement which clears the bolt heads and allows the points to come in contact with the frame at points not subject to wear or incorrect alinement. As shown in the illustration, a 26-in. testing tram is provided to make sure that the square is correct each time before it is used. The testing tram itself may be checked from time to time by means of two points shown on the T-square head 26 in. apart.

Referring to Fig. 4, the T-square is now placed across the frames as shown at A and the box center transferred to the opposite frame. By placing the square on the other side of

ENGINE NO.-----				ENGINE NO.-----			
BOX	GAGE NO.	BOX	GAGE NO.	BOX	GAGE NO.	BOX	GAGE NO.
R-1	1	L-1	1	R-1	1	L-1	3
R-2	1	L-2	1	R-2	2	L-2	4
R-3	1	L-3	1	R-3	1	L-3	1
R-4	1	L-4	1	R-4		L-4	

Fig. 6—Charts Showing Gage Numbers to Which Boxes Must Be Planed

the locomotive frame, the work can be checked by squaring back. If the marks do not coincide, the frames are out of parallel, in which case lines are stretched through the center lines of the cylinders to determine where the frames are out. If the marks check, however, the frames are square and work on the lay-out may proceed.

A careful consideration of Fig. 4 will make the method of

Fig. 7—Jig Used When Drilling 3/8-in. Location Holes

laying-out practically self-evident. A square and straight edge are used, as shown to square down from the top of the frame and proof marks are prick punched 5/8 in. outside of the driving box sizes, the standard box sizes being those shown on the blue prints for the particular class of locomotive involved. When all shoes and wedges are laid out on the outside of the frame, the marks are transferred to the inside of the shoes and wedges, using a back marker, shown at B,

Fig. 4. The vertical positions of the proof marks are transferred as shown at C, Fig. 4. This provides a form of lay-out which is necessary when using the shoe and wedge planer to be described later. The responsibility of the erecting shop, except for a final checking, is now ended.

Machining Driving Boxes, Shoes and Wedges

Driving boxes are delivered to the machine shop, new crown brasses applied and the shoe and wedge fits relined.

Fig. 8—Shoe and Wedge Planer Chuck

The boxes are then placed on a planer and machined to a standard size, using the gage shown in Fig. 5, a separate gage being provided for each class of locomotive. The driving box is then stencilled to show the size between shoe and wedge faces and delivered to the boring mill, where it is bored to actual size, a universal chuck being used to center the box.

It will be noted that the gage illustrated in Fig. 5 is a step gage, each step decreasing by 1/8 in. This arrangement is to provide for light repairs when driving boxes are not rebrassed but simply trued up. The tool is set to whatever step the box will true up at and stencilled 1, 2, 3, 4, 5 or 6, as the case may be. A chart is now made out by the wheel foreman,

Fig. 9—Driving Box Shoe Set Up Ready for Planing

as illustrated in Fig. 6, showing the locomotive number, each driving box number, and the gage number to which it was planed. Two charts are shown in the illustration, one being for a set of driving boxes rebrassed and planed to standard sizes, and the other showing the sizes to which a set of light repair driving boxes were planed without being rebrassed. The chart after being made out is delivered to the man who operates the shoe and wedge planer.

While the driving boxes are being planed, the shoes and wedges are delivered to a sensitive drill, which is placed near the shoe and wedge planer. The jig A, Fig. 7, is then used in drilling the holes which are to hold the shoe or wedge in correct position for planing. As shown in the illustration,

the jig consists of a metal bar with a hardened steel bushing in either end to guide the $\frac{3}{8}$ -in. drill. These bushings are 12 inches apart, as are the two guiding points arranged to enter the proof centers and thus indicate the correct position for the jig. The jig is held in place by means of a pneumatic clamp, as shown in Fig. 7, and two $\frac{3}{8}$ -in. holes are drilled $\frac{1}{4}$ in. deep on each side of the shoe or wedge.

The shoe or wedge is now placed in a chuck, shown in Fig. 8, being held in the correct position for planing by means of $\frac{3}{8}$ -in. pegs in the chuck body entering the $\frac{3}{8}$ -in. holes previously drilled. Two of the $\frac{3}{8}$ -in. pegs are shown in Fig. 8, the other two being machined on the ends of the holding set screws. The jig and chuck, shown in Figs. 7 and 8 respectively, are designed so that when the shoe or wedge is clamped in position the proof center marks are exactly in line with the top of the chuck. A driving box shoe held in position ready for planing is shown in Fig. 9. The proof circles extend $\frac{5}{8}$ in. above the top of the chuck. The gage at A, Fig. 9, is placed on top of the chuck and the planer tool set to the step called for on the chart, previously issued to the planer operator. Thus, if the box is a standard size, the tool is set to No. 1 step; if it has been planed down and is not a standard size, the tool will be set to the required step. It will be noted that steps on the gage increase by

Fig. 10—Pedestal Jaw Grinder Set Up Ready for Operation

$\frac{1}{16}$ in. so that if the driving box is planed $\frac{1}{8}$ in. small, the shoe and wedge by this method will each be planed $\frac{1}{16}$ in. large. The chuck automatically sets up the shoe or wedge parallel ready for planing, and the gage determines the tool setting without any further measurements.

Frame Jaw Grinder

It is necessary to start with frame jaws which are true. With cast steel frames, which are naturally tough and become almost case hardened in service, it is practically impossible to true up a frame jaw by filing. Various attempts have been made to perform this work by machinery and one device was designed to machine the jaws by means of a portable milling machine. The two objections to this device were its lack of rigidity and the danger of removing too much

metal. Obviously the best method would be to use some form of grinding machine which would cut no matter how hard the surface and remove only enough material to true up the jaws. The machine illustrated in Figs. 10 and 11 was devised for this purpose. As shown in the illustrations, power is supplied by means of an air motor driving a 1 in. by 8 in. grinding wheel through one pair of gears. Both the motor and grinding wheel are arranged for vertical movement by means of a square threaded screw, guided by two upright rods securely fastened in the base plate. The grinding wheel is guided in its horizontal movement across the face of the frame jaw by means of the V-ways shown. The device is supported by two bolts through the bottom frame rail, the base plate being held at the required distance from the

Fig. 11—Details of Pedestal Jaw Grinder

rail by means of two pipe thimbles. When it is desired to grind the wedge jaw face a set of pipe thimbles are used which are cut off to hold the base at an angle of 5 deg. This arrangement brings the two machine guides parallel to the frame jaw. A galvanized iron guard is provided for the wheel, as illustrated. Experience has shown that this grinder does a first-class job, especially on wide extension frame jaws, and removes just enough metal to true up the jaws.

PRESS FOR FORMING STACK HOODS

BY C. E. YOCUM

On roads where a hood is used over the stack to avoid setting fires from cinders, the press shown in the sketch will be found a great labor saver. The netting is cut to the

Air Press Reduces Labor in Forming Stack Hoods

proper size and placed centrally over the hole in the base of the press. The air-operated cylinder forces the former down and draws the netting into the proper shape, thus greatly reducing the hand work required.

THE TESTING OF WELDS IN STEEL PLATES*

Conditions Which Affect Quality of Welds; Simple Bend Test and Etching of Sections Recommended

BY S. W. MILLER

Rochester Welding Works, Rochester, N. Y.

THERE have been many failures of welds in the past, some not explained and some very expensive. As in all other developments, welding first received its principal impetus from the practical man. Of late, however, the tendency has been to investigate more carefully and more fully and by means not available to the ordinary welder. This means that scientists of all kinds have been called into consultation and that almost every conceivable method of test has been suggested in order to determine what methods and materials would make the best welds both from a standpoint of security, service and cost. While some of the methods employed at present are beyond the reach of the ordinary welding shop, yet they are of great value and, in fact, necessary in order to determine correctly what has occurred during

Chemical analysis is another powerful method of investigation and many specifications have been made in which its use is vital.

The microscope has been found to be of tremendous help in the study of metals and, in fact it is now a necessary instrument in all laboratories. Its principal function is to determine the extent and location of impurities in a metal, to decide whether the structure is proper for the purpose desired and to decide whether various heat treatments will give satisfactory results. While no one method of test shows everything desired to be known, the microscope is probably the most powerful single method of investigation in the case of metals, and in the study of welds it is particularly valuable because of the method of their formation. A weld is a casting

Fig. 1—Strained iron. The curved lines are not cracks, but the edges of parts of the grains that have slipped past each other. They are called slip bands.

Fig. 2—A good looking oxy-acetylene weld, but made with too large a tip, as shown by the short straight lines in some of the grains.

Fig. 3—Oxy-acetylene weld showing heavy slipping at grain boundary. This is not a crack, but shows a weakness.

the welding operation and what results may be expected under given conditions. Most of the published results are incomplete in one or more respects and one of the objects of the American Welding Society is to put the testing of welds and welded structures on a firm and safe foundation.

Common Methods of Testing

The testing of metals, aside from welds, is quite well developed both in theory and practice. The usual test is the tensile test that gives the tensile strength per square inch, the yield point or elastic limit in pounds per square inch, the elongation in per cent of the original gage length and the reduction of area in per cent of the original section. Compression, torsion, shock and alternating stress tests are also used and the two latter are beginning to be used much more than they have in the past because it has been found that materials may give high results in the tensile test and yet be entirely unsuitable to resist service where shock or alternating stresses are met. Another of the common tests is bending to a certain radius either hot or cold and it has been found that it is a very valuable test of certain qualities.

and is subject to all the defects found in castings, which are, however, exaggerated in the case of welds.

Welds in Steel Plates Only Considered

This paper is confined to defects in the welding of steel plate by the oxy-acetylene and metal electrode processes. The welds considered are those in some important structure where soundness and high quality are necessary. By soundness, I mean freedom from mechanical imperfections such as lack of fusion, the presence of films or other inclusions, gas pockets, slag, etc. Welds of inferior quality may answer some purposes admirably, and if they do, there is no use in making better ones, but this is not the goal at which to aim for one who desires to make really good welds. The welding of steel is frequently considered as not being especially difficult, and it is also sometimes considered that steel is steel and that no different treatment is required in the case of different qualities and varieties of steel. This idea is much less common to-day than it was several years ago, but it is still too prevalent for the good of the art. A comparatively small difference in the percentage of carbon in the material being welded makes a very great difference in the results of either a bend or tensile test. If the carbon is .12 per cent or less, the material is

*A paper read before the September meeting of the Chicago Section of the American Welding Society.

soft, ductile and yields readily to any strain that may be put on it. Such material is frequently used for tanks, and because of its ductility and comparative freedom from damage by heating, is admirably suited for welding. Structural steel, bar steel and boiler plate contain about .15 per cent to .25 per cent carbon and have a tensile strength of about 60,000 lb., while the soft low carbon material has only about 52,000 to 55,000. Ship plate is required to have a tensile strength of

in an oxy-acetylene weld of about 50,000 lb. Neither of these materials will weld boiler steel, boiler plate or ship plate, so that the rupture will occur outside the weld when the section of the weld is the same as the section of the piece, so that in making tests of welded pieces, it is necessary to know accurately the character of the material being welded because if Welder Jones makes a weld in soft tank steel and Smith makes one in bar steel, the first will break outside

Fig. 4—Good oxy-acetylene weld made with rather high carbon steel. Note presence of slip bands as in all good welds.

Fig. 5—Film of foreign matter, probably oxide, in oxy-acetylene weld.

Fig. 6—Inter-granular cracks in strained oxy-acetylene weld. No defects visible before straining, showing that films were very thin.

from 58,000 to 68,000 lb. and in the heavier sections requires as high as .30 per cent carbon.

It has been found by experience that the higher the carbon the more difficult it is to get a satisfactory weld and the more danger there is of injuring the metal being welded. From a metallurgical point of view this is entirely natural and to be expected. It is also evident that a weld made with a given welding rod or electrode can have only a given strength. If this strength is greater than that of the material being welded, the test piece will always break outside of the

of the weld and the latter in the weld with a probable adverse criticism of Smith's work.

Recommended Physical Tests

The method of test to be applied in any given case depends largely on the use to which the welded piece is to be put. If it is to be used in a pressure vessel, I believe that not only should a tensile test be made but that an alternating stress test should be used because of the breathing of the tank due to changes of pressure. This latter test should also be

Fig. 7—Arc weld made probably with too long an arc, as there should not be so much iron nitride.

Fig. 8—Slip bands in arc weld. The heavier straight lines are iron nitride. These weaken the weld little, if any.

Fig. 9—Large defect in arc weld. Dark streak is oxide of iron.

weld. If, on the other hand, the weld is weaker than the material being welded, the rupture will always take place in the weld. An oxy-acetylene weld made with ordinary low carbon welding wire will have a tensile strength of about 52,000 lb. This is stronger than soft tank steel and weaker than the other materials mentioned. It is possible to get with alloy steel rods of proper composition a tensile strength

applied where the weld is subjected to bending strain. There are no standards at present for weld tests, but it is advisable, whenever possible, to follow those of the American Society for Testing Materials. Inasmuch as a welded piece is not of uniform character, it is not possible to use the elongation and reduction of area as commonly measured. Where the break occurs in the weld, the elongation of the whole test piece tells

very little about the quality of the weld, and I have been in the habit of taking the elongation in each inch, two inches, etc., of the gage length, beginning at the center inch, which includes the weld, and plotting these figures, against the gage length. Evidently, when the break is outside the weld, the various physical characteristics are those of the original material and not at all of the weld. The best test, in my opinion, to determine quickly the general character of a weld is to grind it off level with the surface of the pieces and clamp it on an anvil, with the center of the weld level with the top of the anvil, the bottom of the V toward the anvil so that the top of the weld is stretched when the projecting end is struck with a sledge. The blow should not be too heavy and the number of blows and angle to which the piece bends before cracking are quite a good index of the value of the weld. It is true in this test, as in the tensile tests, that the quality of the material being welded has a great influence on the results. Stiff material throws more of the strain into the weld while soft ductile material will itself take considerable of the bend. In the case of defective welds, that is, those not fused along the V or which contain slag or other inclusions, this test will at once develop the defects. If a welded piece were to be used in a place where it might become red hot, such as, for instance, in a locomotive firebox crown sheet, it would be entirely proper to test the weld at a good red heat, and I believe that it would be of much interest to all of you, if you would test some of your welds by clamping them in a heavy vise or on an anvil with the center of the weld about half an inch from the edge of the table or above the face of the anvil, heating them to a bright orange with the torch and then bending them as before with a sledge.

If such welds are made in half-inch by two-inch bar steel, a 90-degree single V being used, and they bend to a right angle cold without cracking on the outside, a welder may feel well satisfied with his work.

Conditions Affecting Quality of Welds

There seems to be quite a definite relation between the thickness of metal, the size of tip and the size of the welding wire, in the case of gas welding, and between the thickness of metal, the diameter of the electrode, and the current used, in electric welding. It is also to be understood that electric welds, except possibly those made with covered electrodes, will not stand as much bending as oxy-acetylene welds.

In many cases, the defects in welds are easily visible to the naked eye when tested. In other cases, they are not, and while it would seem plausible that the visible ones were more dangerous, yet, to my mind, the hidden danger due to the ones that are hard to see is a matter that must not be overlooked. For many years, the dangerous defects in steel rails have been those which were not visible and which have usually been very small at the start. During the war, when the demand for gun steel was very heavy, flaky steel, so called, was the material that gave the government the greatest cause for concern. In fact, those who are best posted on the metallurgy of steel are paying more and more attention to the minor defects, which heretofore have been considered but of little importance. This is equally true in a case of welds and in finding out what a welder can do, this is one of the things that should be examined most carefully. A method for testing rails for these hidden defects has recently been developed by F. M. Waring. It consists of deeply etching a polished surface of the material under test. For instance, a section of a weld might be cut out with a hack saw, machined or filed to a true surface, and polished on various grades of emery paper, ending up with 00 Manning. It is then placed in a warm solution of 25 per cent hydrochloric acid and water for from a half an hour to an hour. The acid will eat away the defects, making the edges of the material at them taper, so that rather large grooves and pits will be visible where the defects prior to the etching

would be only microscopic. It is not really necessary to warm the acid, although it takes longer when it is cold. The bending test, hot and cold, and the etching test are of the greatest value in ordinary shop practice where it is desired to find out rapidly and quite accurately what the quality of the work done by the different welders is.

Effects of Strain

Some of the defects in welds are visible under the microscope, but others are not visible until the weld is strained. A small bending machine that can be placed on the microscope stage is very useful, because after etching, the piece can be bent and examined to see what the effect of the strain is. In the case of bare wire electric welds, the rupture, as far as my experience goes, always occurs at the grain boundaries, even where no defects are visible there at the highest powers of the microscope. Of course, where there are visible defects, the rupture takes place first at these. Where there are no defects, the distortion occurs by slipping in the grains as in normal steel. The causes of these defects are to my mind almost always oxides of one or another constituent of the metal, but usually of iron. There is no positive proof of this as yet, but there are indirect proofs. An electric weld that will bend very little may be made much more ductile by heating in a reducing atmosphere at a low red heat for one or two hours, indicating that the weakness at the grain boundaries has been removed. The reducing atmosphere would seem to make it clear that the material at the grain boundaries was an oxide. Again, heating an electric weld in an oxidizing atmosphere makes it more brittle.

These rough tests, while satisfactory for determining the general quality of the work, do not answer as a basis for design and more refined tests must be used as before referred to. I believe that the most important of these are the tensile and alternating stress tests.

Conclusion

A great deal may be learned from the appearance of a weld. It is difficult to describe the appearance of good welds, but after they have been seen a number of times, an inspector can readily say whether the operator knows what he is doing. In gas welding, I would not accept a ripple weld in heavy material nor one which was narrower than about $2\frac{1}{2}$ times the thickness of the sheet, because I have never seen a weld having these appearances that was properly welded. The appearance of properly made electric welds has been well described by Mr. Escholtz of the Westinghouse Company and has been published in several of the trade journals. The appearance in a gas weld of porosities on top, indicates that the metal has been overheated, and the same thing is true in an electric weld. Inasmuch as I believe that the serious defects in welds are caused by oxides, it would appear wise in the case of gas welding to use no larger tip than is necessary to produce thorough fusion. This means that the catalogue speeds of welding are impossible if good welds are desired. The same thing is true of electric welds. The reason is that at the high temperatures of the steel caused by too large a tip or too heavy a current, the metal becomes overheated, and in that condition combines more readily with the oxygen of the air or with any excess oxygen in the torch flame, and produces oxides which are readily dissolved by the melted metal. As the metal cools down, these oxides are rejected in large part and pass to the grain boundaries, as do other impurities, so that it is perfectly natural that material which has been seriously overheated should be more brittle and weaker than the material which has been properly melted. I have found in a number of cases that very great improvements in the quality of the work were made by using regularly a bending test, and by carefully instructing the welders until their welds meet this test with unflinching regularity.

LABOR SAVING DEVICES ON THE SANTA FE*

Several Effective Methods of Holding and Machining Various Locomotive Parts Are Described in Detail

BY J. ROBERT PHELPS

Apprentice Instructor, Atchison, Topeka & Santa Fe, San Bernardino, Cal.

WITH the present high cost of labor, it is important that every possible effort be made to simplify shop operations and increase the output. One of the best methods of accomplishing this result is to design and install efficient jigs and fixtures wherever possible, thus saving time and in many cases affording more accurate work. The following comparatively simple shop devices have worked out well at San Bernardino:

Drilling Steam Pipe Casings

Much difficulty is sometimes experienced in drilling the connection bolt holes in steam pipe casings. If the attempt is made to hold the casing on a block of wood with one hand and operate the drill lever with the other, there is a considerable chance of either the block or casing slipping with possible injury to the operator or breakage of the drill. The jig illustrated in Fig. 1 has proved both simple and convenient for this work. It consists of a framework of $1\frac{1}{2}$ in.

Fig. 1—Jig for Holding Steam Pipe Casings

by $\frac{1}{2}$ in. iron built up by bending and electric welding and arranged to rest squarely on the drill table. It is fastened to the drill table by a $\frac{3}{4}$ in. by $2\frac{1}{2}$ in. bolt and supports the steam pipe casing in the proper position for drilling. A set screw is provided to hold the casing in place. This device eliminates all blocks, bolts and clamps and is a big time saver, as the casing to be drilled needs no leveling and is quickly applied and removed.

Machining Eccentric Blade Jaws

A device which has proved useful in machining eccentric blade jaws is shown in Fig. 2. It is especially useful when the inside jaws have become worn and are built up by gas or electric welding to take up lateral play. An eccentric blade is shown in Fig. 2, set up on a milling machine table. Referring to the illustration, the Arbor *A* is turned to the standard taper of the eccentric blade pin holes, namely, $\frac{3}{4}$ in. in 12 in. The eccentric blade is set up and securely fastened to the milling machine table so that the arbor is level and square with the table. The boring bar *B*, shown in de-

tail in Fig. 3, is provided with a cutter *C*, held in place by set screw *D*. After the blade has been securely clamped in the correct position, the arbor is removed from the eccentric blade jaws. The boring bar is placed through one side of the pin hole and both inside faces are machined with the

Fig. 2—Eccentric Blade Set Up on Milling Machine

double acting cutter fastened in the boring bar. In addition to getting a smooth, accurate job by this method, there is a big saving in time over the former method of performing the operation on a slotting machine. To care for eccentric

Fig. 3—Details of Boring Bars for Light and Heavy Work

blades with non-standard taper two additional arbors are provided with tapers of $\frac{3}{8}$ in. in 12 in. and $\frac{1}{2}$ in. in 10 in., respectively.

Boring Cylinder Bushings

It may sometimes be necessary to bore high pressure cylinder bushings in a lathe and for this operation some holding device must be employed. An arrangement of four iron bars, provided with set screws, and placed in wooden blocks, as shown in Fig. 4, has been found effective. The blocks are securely fastened together by iron straps and the cylinder is adjusted and held in place by the set screws. Previous practice was to bore blocks to the exact bushing size, place

*The first article written on this subject by Mr. Phelps appeared on page 721 of the November *Railway Mechanical Engineer* and described five efficient jigs and fixtures in use at the San Bernardino shops.

the bushing in the hole and clamp down the block. This practice made it necessary to have seven or eight different sizes of blocks and every time a set became warped or a

Fig. 4—Device for Holding Cylinder Bushings in Lathe While Boring

bushing varied in size, new blocks were required. By the use of the jig illustrated one set of blocks will hold every size of high pressure cylinder bushing in stock. As the bushings are now cast about eight inches shorter and with-

Fig. 5—Throttle Rod Stuffing Box and Jig Used in Drilling Stud Holes

out flanges, there is a saving of three hours' time and 90 lb. of cast iron on every high pressure cylinder bushing.

Drilling Stuffing Box Stud Holes

An arrangement for holding throttle rod stuffing boxes while drilling the two stud holes is shown in Figs. 5 and

Fig. 6—Stuffing Box Set Up Ready for Drilling

6. Owing to the slant or angle of the flange, a large amount of leveling and blocking is necessary to get the stuffing box

face level; not only that, but the blocking in many cases slips out and all the time spent in leveling has been wasted. Where many stuffing boxes have to be drilled, it will certainly pay to make a special jig for holding them. The jig may be made of cast iron or brass. As shown in Fig. 6, it consists of a bushing or piece of tubing just large enough to slip on over the ball joint of the stuffing box. The bushing is cut off to a taper or angle corresponding to that of the stuffing box, an arrangement which brings the stuffing box face horizontal ready for drilling. The stuffing box cannot slide off, being held by its projecting ball joint and the entire arrangement can be held firmly to the drill table by one clamp and with no clumsy blocking.

BROKEN THERMIT WELD

BY J. D. SMITH

One of the back pedestal legs of a locomotive was broken at an old Thermit weld, and it was decided to repair the frame by making a new Thermit weld. It was necessary to cut out a block of steel from the leg as shown at ABCD in the illustration, the distance AC being about 3 in. and the total volume of metal removed about 48 cu. in. The surfaces AB and CD were chipped flat and parallel to the top of the frame. The Thermit box was assembled around the break and risers taken off at the inside and outside of the frame.

After the job was finished and the engine returned to service, within a few days the weld broke along the line AB. Upon examination of the fractured surface, it was found that the Thermit steel had not united firmly with the frame. About one-half of the area was composed of slag and blow holes; the slag, being lighter than the steel, rose to the top, and there coming into contact with a flat horizontal surface, did not all escape up the riser when the heat was poured. The other half was of a very coarse crystalline nature, brittle and easily chipped. It had the appearance of the fracture of a

Position of Weld on Pedestal Jaw

bar of nickel. This was probably due to the fact that the free nickel and the manganese content in the Thermit had not been properly diffused throughout the steel at the time of tapping the crucible. It was probable that the crucible was tapped before the reaction was complete. The mold was pre-heated in the usual manner, but the pre-heating was not carried so far as to bring the chipped surfaces of the frame to the fusing temperature.

It seems reasonable to assume that had the surface AB been faced off at an angle with the top of the frame instead of parallel to it, and the riser taken off at the highest point, the accumulation of slag would have been avoided, as there would have been no tendency to lodge under the frame, and a better weld obtained. Along the surface CD, the weld was perfect, showing that the hot Thermit steel striking that part first, had thoroughly united with it. The breakage of this weld shows the importance of thorough pre-heating of the surfaces, and of allowing the reaction in the crucible to become completed before tapping. In a larger weld, the conditions are somewhat different, as a large volume of liquid steel is employed and the rate of cooling after pre-heating less.

MODERNIZING THE RAILWAY POWER PLANT

Superheated Steam and Other Means Needed to Improve Stationary Plant Capacity and Efficiency

BY R. A. HOLME

Locomotive Superheater Company

THE railroads of this country for their locomotives and stationary power plants use approximately 180,000,000 tons of coal per year, of which 20,000,000 tons, as nearly as can be estimated, are consumed by the railway stationary power plants. Figuring coal conservatively at \$3.50 per ton, the value of the coal consumed in stationary power plants of the railroads for one year is \$70,000,000. This enormous expense should be reduced, and with the application of possible and practical ways and means, worth while savings can be effected.

The average railway stationary power plant is subject to improvement, because outside of a few of the larger shops, equipment of old and antiquated design is being used in the smaller plants. Railway men agree that little attention has been paid to efficiency in the operation of their stationary power plants. There are many ways in which fuel can be saved in these plants. The skill and carefulness of engineers and firemen can be increased, but with the constant changes in the class of labor available, the scarcity of labor and its high wage, it is an exceedingly difficult matter to effect improvements by methods that involve the human factor.

The Government Fuel Administration as well as the Fuel Conservation Section of the Railroad Administration did an inestimable amount of good educational work among the personnel of railway officials. Great improvements resulted from these efforts, but in order to be effective this work must be continued indefinitely.

Stationary Plants Must Be Modernized

We must do more, however, than make the best of the equipment that is being used. The plants now in operation must be modernized by the installation of practical modern devices which lead to a positive increase in economy. These devices should be as far as possible inherently automatic. The utilization of modern and efficient devices will give positive and continuous improvement in fuel economy, whereas old and antiquated plants require continual expenditures to be kept in a reasonably efficient condition. The design of machinery and equipment predetermines the efficiency of a power plant. An incorrectly and poorly designed plant can never be made economical, regardless of how intelligently it is operated. It is essential therefore that all new plants built in the future be designed to give the most economical results, both in the use of fuel as well as in the training of labor.

Modern superheater equipment as applied to stationary plants should show an average saving of 15 per cent in fuel. In a 1,000 h.p. plant using 50 tons of coal a day at \$5 a ton, this saving would amount to about \$14,000 a year. This saving will not only pay for the charges against the investment, but will leave a substantial margin of profit.

Careful consideration should be given to the design and construction of the baffles which form the passage for the hot gases. Leaky baffles result in great waste.

The question of keeping the boilers clean is important and the installation of soot blowers can be made at a very moderate cost. Boilers should also be kept clean internally to prevent the failure of water tubes or boiler plates and to keep down the consumption of coal.

The proper amount of air required for burning the fuel dictates the correct use of dampers. A few railway plants

are equipped with damper regulators and this equipment can be installed at a moderate cost. Another apparatus which results in improved efficiency and one seldom found in a railway plant is the feed regulator, which is a highly successful means toward improving the efficiency and operation of a plant.

The wonderful development in the design and construction of mechanical stokers now makes possible better regulation of the fire and higher economy by the installation of such equipment. Coal and ash handling equipment are improvements which are factors in modernizing the average railway stationary power plant, from which economy is derived.

Advisability of Using Superheated Steam

Superheating theoretically reduces the amount of fuel consumed from 6 to 15 per cent and actual tests have shown fuel saving of better than 20 per cent. Where the cost of fuel is high, therefore, superheating directly applied is a valuable and profitable investment.

The following is a comparison of the steam consumption of different types of engines using saturated steam (under average plant conditions) with those using superheated steam at 100 deg. and 200 deg. Fahr. superheat:—

Type engine	Steam consumption, lb. per hp. hr.		
	Saturated steam	100 deg. superheat	200 deg. superheat
Simple non-condensing	29.45	20.30	18.36
Simple non-condensing automatic	26.40	18.34	16.30
Simple non-condensing Corliss	26.35	18.30
Compound non-condensing	19.28	15.25	13.22
Compound condensing	12.22	10.20	9.17
Simple duplex steam pumps	120-200	80-160
Turbines, non-condensing (kw. hr.)	28.60	24.54	21.48
Turbines, condensing (kw. hr.)	12.42	10.38	9.34

The saving, of course, depends upon the efficiency of the engine itself, but it will be noted that in all cases superheating shows substantial steam economy. The percentage of saving varies from 9 to 33 per cent for 100 deg. superheat to from 19 to 38 per cent for 200 deg. superheat.

Another factor which should be taken into consideration in the modernizing of an existing plant by means of superheating is that of maintenance. The question of maintenance depends on the design and construction of the superheater installed. Under no circumstances should superheater equipment be installed until the existing conditions in a plant have been properly, carefully and thoroughly studied. Recommendations for superheater equipment can be made correctly only after such a study has been made. On these recommendations depend the degree of superheat which can be most advantageously used. In a properly designed superheater the maintenance of the superheater should be no higher than the maintenance of the boiler. It is well to bear in mind that the maintenance of the boiler itself is actually reduced when a superheater properly designed is installed, because superheating so increases the capacity of the boilers that in a battery of superheated boilers the added capacity may make it possible to periodically rest each of the boilers as the other boilers will still have sufficient capacity to carry the load economically. In a plant so designed and so equipped one boiler can be held in reserve, with the result that all of the boilers will last longer and their maintenance cost thereby be reduced.

The superheater equipment should be such that it can be easily maintained by the usual boiler room help and by the

use of such tools as are ordinarily found in the boiler room. It should not be necessary to go outside to secure skilled boiler makers to keep it in first-class operating condition.

Capacity an Important Factor

Not the least important of the factors which indicates the advisability of applying superheated steam is the question of boiler capacity which frequently faces railway officials. We have already seen that superheating decreases the steam consumption of the engine. This decrease may be attributed to the fact that superheating eliminates cylinder condensation, thereby insuring dry steam reaching the engine. With a decrease in steam consumption, due to superheating, a steam reserve is built up, which reserve is available and can be utilized in the engine to take care of its overload capacity, should an additional power demand be required.

Another important factor to be considered is the course which must be pursued by the power plant operator if he is forced by boiler insurance companies to operate his boilers at a lower pressure. The logical result of such pressure reduction is the loss of capacity of the plant, necessitating the possibility of adding another boiler to make up for the loss. Because superheating makes up the loss in boiler capacity caused by the reduction in the pressure, it is a convenient, satisfactory and inexpensive method to overcome the difficulty which obtains in many power plants. Furthermore, the plant operating on superheated steam will furnish more power even under a reduced pressure than it will if it were using saturated steam; in other words, superheating will enable a plant to operate economically and at its original capacity at a reduced pressure.

Long steam lines in many cases have illustrated that the problem of condensation is a serious one and the necessity for reducing this condensation is frequently a vital factor. With superheat, therefore, it may be possible to raise the temperature of the steam to a point where all of the steam can be transmitted to its destination without condensation losses.

HANDLES FOR GRINDING BRACES

BY F. W. B.

Homemade valve grinding braces vary in size and nature to suit the work they are used on, but the handle is usually a troublesome part. The sketch illustrates how a

Grinding Brace Handle Made From Scrap Air Motor Piston

desirable handle can be made from a scrap air motor piston. Discarded pneumatic motor pistons are of all sizes and it is not much trouble to anneal a number of them, cut away some of the wing making a solid durable handle grip that will stay on and run smoothly. The end of the piston rod can be welded to the brace quickly with an acetylene torch.

HOW TO MAKE A GOOD CHISEL*

A large number of the chisels now in use are not forged, shaped and hardened in the best way to give long life and adequate service. Considering the making of a chisel from $\frac{3}{4}$ -in. octagon tool steel, the following method has been found to give good results.

Forging

Cut off a length of steel, depending on the length of chisel desired, and heat up the end for 2 in. to a bright cherry red. Trim off two opposite sides so as to form a blunt nosed tool and eliminate the danger of lapping when drawing out. The horn of the anvil should be used in drawing out, inasmuch as this will have the least possible tendency to widen the piece, and therefore the minimum amount of "edging in" or hammering on the edge will be necessary. A chisel should not be hammered on the edge because the grain of the steel will thereby be distorted or "crumpled up," and this always has a tendency to weaken any metal. If in the final forging operation the chisel gets a little too wide, it can be trimmed off on the emery wheel during the grinding operation.

Draw the chisel out so that it will be about $\frac{1}{8}$ in. thick

Fig. 1

Fig. 2

Fig. 3

Three Methods of Grinding Flat Chisels

at the end and about $\frac{3}{8}$ in. thick and $1\frac{1}{4}$ in. back from the end. The forging should be finished with light blows until the steel has almost lost color, but it absolutely must not be struck after the color has disappeared. It is good practice to reheat the steel to a dull red without using any blast, and give it a second hammering with light blows until the color has again almost disappeared.

The four important things to remember in forging a chisel are, therefore: Draw out at a good cherry red heat; finish with light blows at a dull red heat; do not hammer after the color has disappeared; hammer as little as possible on the edge and then only when the steel is fairly hot.

Grinding

Grind the chisel before it is hardened, as it can be ground faster in this way without the danger of drawing the temper. The shape of the edge of the chisel is very important, although this fact is often overlooked. Fig. 1 shows a chisel ground with a concave edge. If this is driven down onto a flat surface, it is obvious that a great strain will be put on the corners, and they are almost sure to break off. Fig. 2 shows a chisel ground with a perfectly flat edge. If this chisel is driven down onto a flat surface and held perfectly straight the cutting strain will be distributed evenly over the entire edge, and the chisel will be satisfactory. It must be remembered, however, that it is almost impossible to hold a chisel absolutely straight and, therefore, either one corner or the other will be severely stressed by the chisel being tilted over. Fig. 3 shows a chisel ground with a slightly convex edge, which is by far the best for ordinary work. The corners of a chisel are always the danger point, and with the convex edge these

*Abstract of 4-page folder issued by Joseph T. Ryerson & Son, Chicago, Ill., entitled "Do You Know How to Make a Good Chisel?"

corners are protected even when the chisel is tilted over considerably to one side or the other.

Hardening and Tempering

After the chisel has been ground to the desired shape, heat it to a dull cherry red color for about $2\frac{1}{2}$ in. from the end and quench it vertically in cold water to a depth of $1\frac{1}{4}$ in., moving it up and down until no red color is left in any part of the steel. The part which has been drawn out should now be polished with emery cloth and the temper drawn to a dark purple or a blue by holding the chisel over the fire or in a furnace. Always draw a chisel a little more in winter than in summer. It has been recommended to harden the chisel back much further than usual because a chisel so made can be ground a great many times without redressing. Inasmuch as grinding is cheap and redressing is expensive, considerable loss can thereby be avoided.

FOUR FRAME WELDS IN TWO OPERATIONS

An interesting example of the possibilities of Thermit welding was afforded recently by an accident which happened to Baltimore and Ohio locomotive No. 4010 used in hill service. While pushing a heavy train up grade all four

Fig. 1—Appearance of Front Frames Before Welding

front frame sections were broken in front of the cylinders as shown in Fig. 1.

In making repairs, the frames were straightened and the broken ends located in place ready for welding by the Thermit process. As the two pairs of fractures happened to be very

Fig. 2—View Showing Thermit Welds and Front Deck Casting Ready to Be Applied

close together, the top and bottom members of each set were repaired by making only one weld, thus joining both frames together as shown at the arrows in Fig. 2. The result was not only a saving in time, labor and material, but a strength-

ening of the frames at the points welded. After the welds were completed and the deck casting put in place, it was only necessary to ream out the holes and rebolt the casting. These welds were made by J. W. Boyd on April 6, 1920, and the locomotive has since been in constant service.

TRIPLE VALVE GRINDING MACHINE

The device illustrated was designed to eliminate the labor of grinding triple valve slide valves. As shown, the valve is arranged to be held on a stand on the air brake bench. The grinding compound is applied to the slide valve and it is then placed in position on the valve seat. An eccentric with a crank arm and crank is driven by means of a light

Triple Valve Grinding Machine

belt from overhead shafting. The crank arm is arranged to be connected to the slide valve and when power is applied, the valve will be moved back and forward.

When either the slide valve or its seat is badly worn, experience has shown that a long time is required to grind out the irregularities by hand. The slide valve grinding device illustrated has proved a labor-saver for this operation.

CARBON AND HIGH SPEED STEEL*

BY J. PURCELL
Western Pacific

When designing or making a tool from carbon steel we must first consider the proper kind of steel to use and then see that the tool is designed so that it will harden properly without breaking.

Too much cannot be said about the heating and forging of steel, as the heating of steel to forge is one of the most particular of all the operations. The tool dresser must turn the steel over in the forge or furnace to see that it is heated evenly to a little above the hardening temperature, say about 1,475 deg. to 1,500 deg. F. The tool dresser must bear in mind not to forge steel after the forging heat is gone, as the steel will develop small cracks and bad forging strains, which will cause it to crack in hardening.

I consider it good practice to first anneal the rough forging, then have it rough machined and then re-anneal it to take out all possible forging strains; then the tool must be machined to finished sizes. It is then ready for hardening.

In heating any ordinary carbon steel tool to harden, care must be taken not to apply heat too quickly, as this will result in cracking the tool while it is cooling in the hardening

*From a paper presented at the convention of the Master Blacksmiths' Association.

bath. A good practice is to have tools that you are going to harden placed around the forge fire, or, on top of the tool furnace, where they will become slightly heated before they are put into the fire. The tool must have time to heat to the center, otherwise it will crack when it is removed from the hardening bath. A good hardening heat for carbon steel is from 1,400 deg. to 1,450 deg. F.

There are various ways to temper, but we use the oil and thermometer. The tool is placed in the bath of oil, which has a thermometer attached and the bath is placed in the furnace. The oil is brought up to the required temperature, the tools are removed from the oil and put into a vat containing lye to remove the oil, then quickly removed from the bath and allowed to cool in the open air. We draw the temper from 380 deg. to 590 deg. F., according to the amount of carbon in the steel.

The forging, hardening, and tempering of high speed steel is carried on by practically the same methods as carbon steel, except at a much higher temperature. We forge our high speed steel between 1,875 deg. and 1,925 deg., harden between 2,300 deg. and 2,350 deg. F., and let the temper down to about 600 deg. F.

AIR COMPRESSOR STAND

All shop men are familiar with the difficulty of handling air compressors, especially the heavy Westinghouse cross compound compressors. Many different kinds of tables or stands have been devised for holding them while under repair and the one illustrated has proved both simple in construction and efficient for this purpose.

As shown, the stand itself is composed of built up sections of pipe. Two iron brackets are arranged to be solidly fastened, one on either side of the compressor, by means of pipe studs in the air and steam intake and exhaust passages. On each bracket there is a projecting center arranged so that

Stand Arranged to Swivel Air Compressor

both the compressor and brackets will be suspended at the center of gravity of the compressor. By this means, a compressor can be easily swiveled at any angle, or upside down, whichever position is most convenient for the workman. Dogs are arranged to hold the compressor firmly in either the horizontal or vertical position.

In operation, the compressor is first thoroughly cleaned and the brackets put in place. A monorail crane then lifts the compressor and brackets, setting them down at whatever compressor stand may be vacant. In this way, practically no trucking by hand is required and there is a big saving in labor.

HEAT TREATMENT OF FORMING TOOLS FOR WHEEL LATHES

BY FRANK D. KENNEY

Toolmaker, Billerica Shops, Boston & Maine

There are a great many factors to be considered in explaining why a certain tool does extraordinarily good work. When all other factors remain constant and the tool efficiency is improved by changes in heat treatment, it is possible to arrive at a point where breakage is practically eliminated and the tool does its greatest amount of work. The heat treatment directly responsible for such a tool is of more than passing interest.

Wheel lathe forming tools giving the maximum amount of service at Billerica Shops are made of a well-known brand of high speed steel. They are about 6 in. long, 4 in. wide

Wheel Lathe Forming Tool

and 1 1/2 in. thick. On one of the 6 in. sides, a profile of the tread and flange of the tire is milled. The other long side is shouldered in about 1/4 in. leaving a square rib on the lower edge which fits into a slot on the tool post. Two holes are drilled in the proper places to allow for bolting to the machine.

For the heat treatment of these tools, the one thing that is necessary is equipment. Not necessarily expensive equipment but efficient equipment must be provided if it is desired to obtain good results, and duplicate them to any degree of accuracy. For heat treating forming tools, four crude oil-fired furnaces, pyrometers, thermometers, etc., are used. The larger of the furnaces is held at a heat of from 1,400 deg. F. to 1,450 deg. F. and used for carbon steel; also for pre-heating high speed steel. Adjacent to this is the high heat furnace for the hardening of high speed steel, held between 2,250 deg. F. and 2,300 deg. F. Then there is the lead bath which is held at about 750 deg. F. and used for both quenching and drawing forming tools among other operations. Finally there is the tempering furnace used in drawing operations up to 600 deg. F.

Forming tools come to the tool room for treatment in pairs, a right and a left. They are laid on the roof of the carbon steel furnace and left there until too hot to handle with the hands. They are then removed to just inside the door of the 1,450 deg. F. furnace, which spot happens to be the coolest place within the oven. After becoming warm, they are gradually worked toward the center of the furnace. When the steel becomes thoroughly heated to the temperature of the oven, the tools are ready for the high heat. They are placed in the 2,300 deg. F. furnace one at a time, each tool being constantly watched and frequently turned and moved about to insure uniform heating. When the last "shadow" has left the center of the tool, and the surface looks glossy and wet, and when little bubbles seem about to form, or in other words when the tool attains the proper hardening temperature, it is removed and placed in the lead bath which has been previously heated to 750 deg. F. and quenched therein.

On account of the lead having a higher specific gravity than steel, the tool must be weighted to keep it wholly immersed in the bath. This is done for the want of a better way, by means of a heavy block of iron long enough so that one end rests on the edge of the pot and the other on the tool which is dipped endwise. This added weight keeps the tool covered with lead. The use of the lead as a quenching medium positively eliminates breakage, a fact which in itself is reason enough for its use. The second tool which was left in the 1,500 deg. F. oven goes through the same operation and both are left to cool to the temperature of the lead.

In drawing, we take advantage of that phenomenon in high speed steel treating known as secondary hardness or the 1,100 deg. F. draw. The pot is heated slowly to between 1,050 deg. F. and 1,100 deg. F., and the tools are allowed to soak at this temperature ten or fifteen minutes, after which they are removed and allowed to cool naturally. Care must be taken not to heat the tools about 1,100 deg. F., as beyond this point there is a sharp loss of high speed steel's greatest asset, that of red hardness.

The one bad feature of lead as a quenching medium is the fact that it has a tendency to stick to the work with the resultant glazing of emery wheels and trouble in general trying to get it off. This can be overcome to a great extent by using

Heat Treating Corner of Toolroom

a piece of oily waste which, if rubbed briskly over the tool immediately after leaving the bath, will remove most of the lead. The two points of the operation that must be most carefully observed are the above mentioned caution of not drawing above 1,100 deg. F., and the temperature at which the tools are quenched. Subsequent operations all depend on the quenching temperature and, of course, are of no value without the proper hardening to begin with.

In regard to the 1,100 deg. F. drawing temperature, some very definite conclusions may be drawn from a paper prepared by the chief metallurgist of a leading machine tool manufacturer. From each of twelve different brands of high speed steel used in a test, four milling cutters were made. These were all heated and quenched alike (heated to 2,300 deg. F. and quenched in oil at 100 deg. F.). Two of the cutters from each brand were drawn to 450 deg. F., and the remaining duplicate set was drawn to 1,100 deg. F. A comparison of the hardness numbers made before and after the 1,100 deg. F. draw showed that two of the steels actually gained in hardness. Probably the most valuable data given

was that made while the tools were checked under actual working conditions, which is in the last analysis the only real test of a tool. Tools drawn to 1,100 deg. F. in every case gave greater production than the ones drawn to 450 deg. F., and in some cases two or three times as much. These final phases of the experiment prove conclusively the great value of secondary hardness.

FLUE HOLE CUTTER

BY A. G. JOHNSON

Mech. Engr., D. & I. R., Two Harbors, Minn.

The illustrations show a special cutter used to make holes in firebox flue sheets for superheater flues. It is also adaptable to cutting holes in front flue sheets which, however, seldom need to be renewed. The cutter is used in a heavy drill press or radial drill.

The shank is turned to a number five Morse taper and the

Assembled Flue Hole Cutter

guiding end is made of tempered tool steel. The center piece is a piece of soft steel, screwed onto the shank. Square slots are milled so that the cutting edges of the tools will come exactly on the center lines. The finished ring is shrunk on, then drilled and tapped for the safety set screws.

The cutters, which are made of 5/8 in. square tool steel, are held in place by the safety set screws shown and a plate is fastened on the back to prevent them from coming out. The tools are now dressed up on the grinding wheel and turned inside and out, with the grinder, to the exact size circle

Sketch Showing Cutter Details

required. It will be noted that two tools are ground to cut on the outside and the remaining two are ground to cut on the inside so each continuously leaves clearance for the other, which makes a smooth job. Oil holes are put in, one for each tool and one for the center pin.

In operation the sheet is first layed out and flanged, the centers for flue holes being drilled 1 5/8 in. in diameter to guide the cutters. Finished holes are cut in the sheet, at the rate of one every five minutes, through a 1/2 in. sheet.

One hundred and ninety holes have been cut through 1/2 in. plates with one set of tools without regrinding.

Self-Contained Cylindrical Grinding Machine

A NEW cylindrical grinding machine developed by the Norton Company, Worcester, Mass., embodies two important departures from previous practice. The new machine, known as the 10-in. by 72-in. Type B grinder, is entirely self-contained, being arranged for electric motor drive with the motor an integral part of the machine. This eliminates all overhead shafting and belts. The second noteworthy feature is the table speed obtained. In the past, it has been difficult to obtain a table speed of over 10 ft.

per min. glasses in front of the operator. The spindle bearing adjustment is simple and the operator can cause the bearings to close tight upon the oil film on the spindle by simply turning the thumb screws until he cannot turn them any more. This adjustment is made at any time while the spindle is running. The end thrust also is adjusted by a thumb screw.

The spindle is driven by a belt from the power shaft enclosed in the base. Owing to the belt pull being down-

Norton Type B Cylindrical Grinding Machine of 10-in. by 72-in. Capacity

per min. but by means of a patented reversing mechanism which reduces the shock and noise at reversal, the new Norton grinder provides table speeds from 10 to 32 ft. per min.

The head stock work drive is by means of spiral and worm gearing entirely enclosed in oil. The rotation of the work is started or stopped simultaneously with the table or alone by the use of a quick-acting lever and a multiple disc clutch. The footstock of the grinder is of improved construction combining the screw and lever types. Adjustment for the spindle fit can be made over its entire length at any time.

The wheel head or wheel slide is of massive construction and hollow containing a chain-driven pump and oil reservoir for oiling the wheel spindle and end thrust bearings. The oil supply to the spindle bearings is visible through two

ward instead of up, it is possible to transmit a greater amount of power to the wheel spindle than in former drives. An idler is provided to take up slack in the belt.

The work table is of improved construction to secure neatness in the care of the grinding compound. The sliding table is started and stopped either simultaneously with the work or separately as desired. The speed changes for the table are transmitted by means of heat-treated sliding gears and positive clutches in an oil bath. There is an independent table speed for truing the wheel which is obtained by moving a lever for this purpose only. The proper speed is obtained at once regardless of which work traverse speed may be in gear and is returned to the original table speed by moving the same lever back.

A quick-acting hand cross traverse for the wheel slide

and an improved micrometer adjustment for sizing work are provided. The in-feed is operated either at each end of the table stroke, or when the table is still for a direct in-cut. The change is made by the simple movement of a lever.

The pump tank and settling tank are integral, mounted

Rear View of Grinder Showing Setting Tank, Headstock Drive Mechanism and Driving Motor

upon ball-bearing truck wheels, so that the tank is in reality a dump cart on wheels. The pump is arranged to swivel on its driving-shaft axis and can be swung up out of the tank and the tank removed to dump while a duplicate filled with clean compound is rolled into place. The time required for changing the tank is only from three to five minutes. The steadyrests are of improved construction. They have thumb-screw stop adjustment for size of work and are attached or detached quickly by a lever and cam. The work shoes and work-shoe holders are interchangeable with previous types of Norton grinding machines.

Special attention has been paid, in the designing of the

machine, to the lubrication of bearings. With the exception of a few places where it is not essential that the oiling be frequent, all the bearings are automatically oiled. There are also 47 ball bearings throughout the machine, all of which are enclosed in oil baths.

Six work speeds are provided ranging from 53 to 167 r. p. m. There are seven speeds for the work table. A truing speed of 2.3 ft. per min. can be obtained and regular speeds vary from 10 to 32 ft. per min. The length of the table is 8 ft. 10 3/4 in. Cylindrical work 72 in. long and up to 10 in. in diameter can be ground. Each tooth in the

View of Wheel-head Showing Bearing Adjustment Screws

index gear represents a work diameter reduction of .00025 in. and there is an automatic feed range from .00025 to .0035 in. diameter reduction at each reversal of the table. A 15-hp. motor, designed to operate at a constant speed of 1,200 r. p. m., is required to drive the new Norton grinder.

Collapsible Tap of Simple Rugged Design

THE original and outstanding feature of the new collapsible tap, made by the Rickert-Shafer Company, Erie, Pa., is the method of withdrawing the chasers when the work has been tapped to the required depth. The manufacturers claim it to be positive in action, inasmuch

that the chasers will be released at exactly the right point.

The illustrations show the manner in which this is accomplished. At the point of release the force of the cut pulls the head from the locking pins and revolves it. This action causes the cams on the core to act and pull the core back, drawing the chasers in the head and clearing them from the

Rickert-Shafer Collapsible Tap

as it is impossible for it to stick. This is a decided advantage in all cases, but especially so where work has to be tapped close to the bottom of the hole, in which case the operator can place full reliance upon the tool, as it is stated

View Showing Mechanical Details of Collapsible Tap

work. It will be seen that in this tool no dependence is placed upon springs for the purpose of collapsing.

Attention is also directed to the method of making adjustments, which allows these to be made to the fractional thousandths. A guarantee accompanies these taps that they will

hold to size, within the most exacting limits, and that sizing hand taps can absolutely be dispensed with.

These tools have hardened and ground wearing parts and scientifically accurate chasers. They are manufactured in

sizes from 1 in. to 10 in., or larger, and can also be combined with boring, reaming or chamfering tools, thus greatly increasing production by eliminating additional operations and set-ups.

Heavy Duty Continuous Milling Machine

THE continuous milling machine of the ring table type illustrated herewith has been developed by the Newton Machine Tool Works, Inc., Philadelphia, Pa. The base of the machine is circular in form, providing a central taper column. The table casting is fitted to the central taper column of the base, and in addition is provided with an annular bearing close to the periphery of the table. The cross rail and the central upright are made in one piece so as to reduce the number of bolted connections.

The machine table is 84 in. in diameter and the depth from the annular bearing to the top of the table is 12 in. The least diameter of the taper fit between base column and table is 36 in. The table is provided with a finished hub 42 in. in diameter to assist in locating jigs on the table. The central column is bolted and keyed to the base and the cross rail is fitted in the front with one housing containing two spindles for the roughing cut. On the back of the cross rail and at a distance of 42 in. is a similar housing carrying a single spindle for the finishing cut.

Both housings for the roughing and finishing spindles can be positioned on the cross rail so that, where the machine is used for a variety of work, the spindles can be positioned to the most economical location of the jigs upon the table. The outer end of the cross rail is supported by a column which is bolted and doweled to the base as well as the cross rail. Motor drive is provided on top of the machine, the motor being geared to a jack-shaft. At the extreme outer end of the cross rail there is a box used to transmit the motion from the jack-shaft to the roughing and finishing spindles. This permits of varying the rotative speed of the spindles independently of each other and, while the speed is predetermined and fixed, this provision permits of changing the speeds when the grade of material or size of cutters is changed, a necessary feature if the maximum efficiency of cutting tools is to be utilized.

The rotative movement of the table is controlled by a fixed feed which is predetermined, but can be changed to suit any change in the grade of material. There is not, however, any possibility of the operator increasing or decreasing the production of the machine as the rotative speed has been predetermined. This means that a given number of stations per hour must pass the loading station, hence that number of pieces must be machined or require an explanation.

The table itself is rotated by a herringbone gear 81 in. in diameter. Each of the spindles is provided with an individual adjustment for setting the cutters to gages. Different sizes of housings providing varying centers between the roughing spindles are used, depending upon the dimensions of the work. Generally, however, these centers are either 12 in. or 14 in. Both spindles are rotated inward or clockwise

Newton Ring Table Type Continuous Milling Machine

on the left hand spindle and counter clockwise on the right hand spindle.

With the distance of 42 in. from the center of the roughing cutters to the center of the finishing cutters, it is quite clear that the roughing operation has been performed on a given casting before the finishing operation commences, hence the finishing cutter is relieved of any influence on the part of the roughing operation and, due to the slight cut taken by the finishing cutter, any inaccuracy resulting from either dull roughing cutters or inequality of castings is picked up by the

finishing cutter, insuring accuracy of both finish and dimension. The principle of roughing and finishing cuts permits of operating at much higher cutting speeds and table feeds than is practical by any other process of surfacing operations.

All bearings, except the spindle bearings, are oiled by the cascade method of lubrication. Oil is pumped from a reservoir in the outer upright to the box on top of the machine, from which point it is distributed.

An important element is the extreme ruggedness of all operating parts and an excessive amount of weight is provided in view of the fact that the parts machined are quite incapable of absorbing any of the vibration set up by all cutting actions. The machine is designed to absorb and dissipate such vibration. The character of the work usually presented to these machines does not require a great range of adjustment, hence with the standardized model, this is taken

up, first, by the adjustment in the spindle heads and second, by variation in the height of the jigs themselves.

The work presents itself to the cutters at varying angles providing that shearing action which it is recognized gives the best cutting results. Also the inner or right hand cutter is further advanced than the left hand cutter. This is a good feature because the cutters are not on a radial line, hence the inner cutter does cut considerably in advance of the outer cutter, a condition which permits of the use of a head with 14 in. centers equipped with 12 in. cutters to completely cover a surface which by any other method would require that the cutters be interlocked.

The planing of journal boxes in car machine shops is a more or less difficult operation and it seems probable that the Newton ring table type continuous miller would prove valuable in the quantity production of these and similar parts.

Preheating Furnace for Welding Work

THE success of welding depends not only on the skill of the welder but also on the manner in which the job is prepared for welding. Experience has taught that metal cannot be welded cold, because as the weld cools it contracts and pulls away from the cold metal in the casting, thus rendering the job useless. Proper preheating is one of the principal factors in reducing welding costs, and it is

Hauck Preheating Furnace

claimed that the consumption of welding gases can be reduced from 50 to 75 per cent where a good preheating medium is used.

A practical and satisfactory furnace for preheating, made by the Hauck Manufacturing Company, Brooklyn, N. Y.,

is shown in the illustration. It consists of a deep box or oven, with a detachable cover, mounted on a preheating table. The box is large enough to accommodate a block of six automobile cylinders and other small parts at the same time. It is equipped with three sliding doors, enabling the operator to watch the work and see that it is not overheated. The inside of the box is lined with asbestos, which retains the heat, and the oven can be used for reheating after welding. The burners can then be turned off and the castings allowed to cool gradually.

By removing the box and cover, the furnace is converted into a preheating table. The combustion chambers, through which the flames of the kerosene preheating burners travel, are lined with a patented type of refractory brick, which breaks the flame up into a number of small, soft, radiating flames. This is an important item in evenly and thoroughly transmitting the heat to the castings or broken machine parts.

The furnace has been found valuable for such work as welding gears, crank-cases, and other parts with comparatively large areas and of intricate formation. The even heating prevents cracking and avoids any possibility of unequal expansion.

Frequently, for unusually heavy, cumbersome parts, the preheating can safely be confined to the break, without heating the entire casting. Loose fire bricks or sheet asbestos are used in this case with one or two of the Hauck preheating burners. The table is then called into service, the part placed thereon and the work started. The burners shown are the so-called hand pump type using vaporized kerosene oil as fuel.

Spiral Tooth Cutter and Grinding Machine

THE advantages of spiral cut teeth have long been recognized by users of plain milling cutters. As contrasted with the blow struck by each successive tooth of a straight tooth cutter, the progressive shearing cut with spiral teeth, assures a smooth even surface and permits the use of greater feeds and faster speeds. With these points well in mind, the Pratt & Whitney Company, Hartford, Conn., has developed a formed milling cutter with spiral teeth and eccentric relief to be sold under the trade name of Curvex cutters.

At present, there are in general use two distinct types of cutters for milling contours. The eccentrically relieved formed milling cutters are produced by a broad lathe tool, having a cutting edge of the same contour as the work to

be milled. These cutters have the distinct advantage that they can be resharpened by grinding on the face of the tool without changing the form. The contour ground cutter was developed for smoother work and greater freedom in cutting. It is made by gashing the teeth to approximate the desired contour and then finished by grinding each tooth to correspond to a template or former.

Both of the above cutters have straight teeth and consequently are handicapped for production work as the feeds, speeds and depth of cuts have to be restricted in order to produce a smooth surface. It is claimed that Curvex cutters combine all the advantages of the older types of formed cutters, eccentric relief, free cutting qualities and accuracy. In addition to these, they have the advantage of spiral teeth

with the resultant smoothness of cutting and greater feeds and speeds available.

A wide range of sizes is provided and the cutters can be made to order with right or left hand spirals, having prac-

Curvex Spiral Tooth Milling Cutters

tically any lead from 1.607 to 125 in. and with any helix angle up to 20 deg. Due to the fact that no expensive forming tool is necessary these cutters can be manufactured at a slight additional cost over the price of ordinary formed milling cutters.

Curvex Cutter Grinder

While designed especially for grinding Curvex cutters, this machine can also be used on all types of milling cutters

Front View of Cutter Grinder

and hobs with straight cut teeth. It is also adapted for grinding fluted reamers and similar tools. The machine is equipped with a conical grinding wheel which presents but a single line of contact between the wheel and the work at any one time. The wheel may therefore be made to follow accurately the helical path of the tooth and grind the cutting edge to the required form. There is always considerable difficulty in sharpening spiral hobs with a flat face wheel

which is inferior to the cone shaped wheel both as regards accuracy and free cutting.

In grinding the teeth to the required helical path, the machine imparts a combined traverse and rotary movement to the cutter. The table on which the cutter is mounted can be swivelled horizontally about an axis which intersects the axis of the spindle and grinding wheel. When grinding Curvex cutters, the table is swivelled at an angle to corre-

Pratt & Whitney Special Cutter Grinder

spond to the helix angle of the cutter teeth. It is then reciprocated in the usual way by means of a handle operating a rack and pinion. At the same time a reciprocal rotary movement is imparted to the cutter through a set of change gears selected to conform to the lead of the cutter.

An indexing device is provided for successively bringing the teeth in line for grinding instead of holding the back of the tooth against a spring stop. Another interesting feature is the arrangement by which cutters of different sizes can be ground radially without resetting the head or table. The surface of the grinding wheel is kept dressed to the correct shape by means of an accurately mounted diamond. Provision is further made for adjusting this diamond from time to time so as to maintain the true cone angle of the grinding wheel. The machine is arranged for wet grinding which is a feature tending to promote increased production.

Meno Rust Remover and Cleanser

A PREPARATION known as Meno rust remover and cleanser has been developed to remove rust from machines, engines, tools, and all metal surfaces, thereby greatly reducing the time and labor previously required for this work. The compound is a blending of certain chemical ingredients, which in combination produce an electro-chemical action that rapidly loosens and dissolves rust, corrosion, grease, oil, dirt, carbon, paint or any other

foreign substance adhering to the metal, irrespective of its age or hardness. It is stated that the action automatically ceases when contact between the cleanser and the metal is established, and it will not injure or mar the surface of the metal itself. One important use of the preparation in railway shops would be in cleaning motion work before repairing it.

The preparation may be applied with a brush or by dipping. It will not burn or explode and protects the metal and

makes it exempt from corrosive or disintegrating action for a long period after treatment. The preparation is an economical one to use, as it does not deteriorate or lose its cleansing power and the same solution may be used many

times over. Peter A. Frasse & Company, Inc., New York, are the sole distributors, and are now establishing agencies in various parts of the country for the sale of this preparation.

Turret Lathe for Intensive Production

By the elimination of speeds and feeds not actually necessary for the best high speed production practice, it has been possible to simplify greatly the geared head of the turret lathe illustrated, which is made by the Millholland Machine Company, Indianapolis, Ind. Only four geared spindle speed changes are furnished, it being maintained that greater production can be obtained where too much reliance is not placed on the operator's judgment as to the speeds and feeds to be used.

Eight broad-face gears and two friction assemblies are provided in the geared head illustrated. A two-step driving pulley is mounted on the back-shaft and provides eight speed changes. But few changes have been made in the friction assembly over other types manufactured by this company. Large driving surfaces are provided with simple adjustments for wear. A bath of oil assures ample lubrication and resultant long life to all moving parts.

Arrangements are made for placing a motor on the headstock cover when individual motor drive is desired. Sight feed lubricators are provided for the main spindle and back-shaft bearings. Except for changes in the geared heads, this turret lathe is designed along the same lines as previous models. The tool-post carriage spans the bed, and is arranged to be brought close to the head of the machine, permitting the use of short, sturdy tools. The turret slide and saddle unit is provided with a taper base and taper gibs for horizontal and vertical adjustment. It is operated by a rack and pinion movement, being automatically indexed on the backward movement of the slide.

Both the turret and its feed mechanism are interchangeable

stops, operating automatically for each position of the turret. Broad bearings are provided for the cut-off slide, which is constructed to insure rigidity under heavy forming and turning cuts. The hand longitudinal feed adjustment is

Gearing Arrangement in Headstock

provided with adjustable clips on a dial so that shoulder positions may be duplicated.

The turret lathe bed is of box section, well ribbed and provided with a pressed steel oil pan and cast iron reservoir

No. 6 Millholland Turret Lathe of 2½-in. Bar Capacity

able with that of the corresponding size cone-head machine. Engagement of the turret feed is by means of the lever of the friction clutch, and eight speed changes are available. The feeds are automatically tripped by independent adjust-

underneath. A pump, driven by a pulley on the back gear shaft, furnishes ample cutting lubrication. The new turret lathe is made in three sizes, Nos. 3, 4 and 6, having automatic chuck capacities of 1¾-in., 1⅝-in. and 2½-in., re-

spectively. The diameters of swing over the turret slide are 6 in., $6\frac{3}{4}$ in. and 8 in., respectively. The lengths that can be turned are 8 in., 10 in. and 14 in. The respective

diameters of swing over bed are $16\frac{1}{2}$ in., $18\frac{3}{4}$ in. and $21\frac{3}{4}$ in. Pulleys on the countershafts are recommended to run at speeds of 345, 306 and 283 r.p.m.

Light Weight Portable Pneumatic Grinder

A LIGHT pneumatic grinder, using 6 or 8-in. wheels and weighing 14 lb., has been placed on the market recently by the Roto Pneumatic Company, Cleveland, Ohio. The grinder is simple in both design and construction, there being but three moving parts. The shaft assembly with pistons rigidly mounted constitutes a single rotating member.

Roto Pneumatic Grinding Machine

This, in combination with two self-sealing sliding valves, forms the only moving parts in the motor. By eliminating crank shafts and connecting rods, friction and maintenance costs are greatly reduced. Another advantage is the reduction of motor vibration.

In operation compressed air enters the machine through the control handle and is applied to the pistons in the direction in which the shaft rotates. The turn-handle air control of the motor is self-sealing, absolutely balanced and the throttle will stay in any position in which it is placed by the operator. This control valve will throttle to zero without causing any intermittent pulsation, and when the throttle is closed suddenly, the motor valves automatically release, permitting the air to by-pass and allow the motor to idle down gradually. The air port areas are large and the maximum amount of grinding power can be obtained from the air. Under average conditions about 15 to 20 cu. ft. of free air per min. at 80 lb. pressure are consumed.

The cylinders and valve chest of the motor are of bronze, and bronze bearings are used throughout the machine. The motor bearings are thoroughly lubricated through the center of the shaft from an oil reservoir in the handle of the motor.

Another practical advantage of the machine is the direction of rotation of the grinder, which is such that the sparks and chips are thrown away from the operator and the load of grinding toward him. The machine is adapted for light grinding work around machine shops, such as grinding castings, dressing gas or arc welds, and other miscellaneous grinding work.

Electrical Speed Control for Automatics

MANY advantages in the way of increased flexibility and ease of operation have resulted in the past from the application of electrical speed control to various types of machines. Recognizing this fact, the Cleveland

device is particularly valuable in the case of automatic screw machinery because it is often necessary to rotate the work at different speeds for each successive tool set-up and operation. Various different types of mechanism were exper-

Fig. 1—Large Electrically Controlled Cleveland Automatic Provided With One Driving Motor

Automatic Machine Company, Cleveland, Ohio, after experimenting for a period of two years, has finally developed an automatically controlled spindle speed-changing mechanism to be applied to Cleveland automatic screw machines. This

experimented with, some of which were automatic and others semi-automatic, or hand operated. The objection to the latter type was that it required one operator for each machine. The machine illustrated is provided with an automatic

mechanism which varies the speed of an adjustable speed-driving motor by regulating the resistance in series with the shunt field windings. It is possible with this mechanism to maintain the correct cutting speed for each tool.

Cleveland automatic screw machines, provided with electrical control, are known as type A automatics. The 1½-in., 2-in., 2½-in., 3-in. and 3½-in. sizes are equipped with two electric motors. One of these is of the adjustable speed reversible type, and is used for driving the spindle only. The other motor runs at constant speed and drives other parts of the machine, including the patented automatic spindle speed controller. The larger, type A automatics, with capacities from 4½ in. to 7¾ in., are provided with only one electric motor. These machines are not furnished with back gears, so that eight changes of spindle speed only are available. Also, because no threading is done on the larger machines, there is no provision for reversing the direction of spindle rotation. As only one motor is used, the power is transmitted to a shaft running along the back of the machine to carry movement to all other members of the machine. Sixteen changes of spindle speed are available on the smaller sized machine, giving a range of 10 to 1 in either direction at any point in the cycle.

Method of Obtaining Automatic Control

Front and rear views of the control mechanism are shown in Figs. 2 and 3. Reference to Fig. 1 shows a push button at *A* which controls the starting and stopping of both motors through a main switch. The drum *B* shown in Figs. 2 and 3, is mounted at the end of the main cam shaft. Other cams

Fig. 2—View Showing Automatic Control Mechanism

on this shaft are so arranged as to properly time all the automatic movements of the machine.

In the smaller sizes of automatics the cam drum *B* is provided with three cams for starting, stopping and reversing the spindle driving motor. Two other cams provide for engaging the high and low speed gears, and the eight cams operate the controller to obtain any of the available speeds. Referring to Fig. 2, the function performed by the several cams, carried on the drum *B*, are plainly marked on the cover plate over the box. In the case of the eight cams that effect speed changes, the speeds that are secured with each cam when the spindle is driven through the high-speed and through the low-speed gears are shown. Each cam engages its respective controller lever at some point in the revolution of the cam shaft. The desired result, in the case of speed changes, is secured when the cams come successively into

engagement with respective controller levers when the contacts are carried into engagement with corresponding contacts in the controller box. This results in a variation in field resistance and changes the motor speeds as desired.

The electrical connections are made by a combination rubbing and rolling action that keeps the surface contact clean. Engagement of the high or low speed gears is secured by means of two cams and control levers that operate a solenoid. One complete revolution of the cam shaft and drum *B* means that each cam has performed its function and the finished piece of work has been cut from the bar. A control panel *D* is located at the rear of the spindle-driving

Fig. 3—Automatic Control Mechanism With Cover Plate Removed

motor, and contains the main switch, accelerators and overload coils for both motors. The overload coils are arranged so that an overload on either motor stops the whole machine.

Advantages of Electrical Control

As an example of the flexibility of the Cleveland automatic, due to electrical control, it is maintained that the peripheral speed in a cutting-off operation can be held constant by increasing the speed at which the work is rotated as the tool approaches the center. Maximum production is secured because the cutting speed can be held at the most efficient rate for each operation. Other advantages claimed for this machine are individual motor drive, ease of set-up, and spindle speed changes effected from a standing position as readily as changes in feed.

French Passenger Locomotive in Nevers Shop

Railway Mechanical Engineer

Entered at the Post Office at New York, N. Y., as mail matter of the second class.

Subscriptions, including the eight daily editions of the *Railway Age*, published in June, in connection with the annual convention of the American Railroad Association. Section III—Mechanical, payable in advance and postage free: United States, east of the Mississippi river, \$3.00 a year; west of Mississippi river and Canada, \$5.00 a year; elsewhere \$5.00, or £1 5s. 0d. a year. Foreign subscriptions may be paid through our London office, 34 Victoria Street, S. W. 1., in £ s. d. Single copy, 30 cents.

WE GUARANTEE, that of this issue 10,300 copies were printed; that of these 10,300 copies, 9,295 were mailed to regular paid subscribers, 5 were provided for counter and news company sales, 263 were mailed to advertisers, 32 were mailed to employees and correspondents, and 705 were provided for new subscriptions, samples, copies lost in the mail and office use; that the total copies printed this year to date were 137,350, an average of 11,446 copies a month.

The *Railway Mechanical Engineer* is a member of the Associated Business Papers (A. B. P.) and the Audit Bureau of Circulations (A. B. C.).

Americanization of foreign-born employees, which has been carried on by the Pennsylvania Railroad systematically for several years, has now been extended to the wives of such employees, plans looking to action in this direction having been adopted at a meeting of the Pennsylvania Railroad Women's Club, in Philadelphia. The Pennsylvania Railroad Mutual Aid Society will co-operate in carrying out these plans.

The recent wrecking of an express train outside of Paris, which resulted in the death of nearly 50 persons, and injuries to many more, is causing the French government to consider the need for the adoption of continuous brakes on freight cars. The accident was caused by several cars becoming uncoupled and crashing into the forward section of the train when it was brought to a stop. The damaged cars blocked the track of the express which arrived immediately after.

The Empire State Express, of the New York Central, has now been running 29 years; Tuesday, October 26, having been the anniversary of the first trip. A sketch of the history of the train is given in the *New York Central Magazine* for October. For many years the train ran through, westbound, New York to Buffalo, 439 miles, in eight hours, with four stops. As patronage increased, necessitating the lengthening of the train to the capacity of the locomotives, the speed was lowered, and the schedule time is now nine hours. In connection with this notice the Magazine denies the rumor, recently printed in various papers, that engine No. 999, which hauled this train on the Mohawk division for a number of years, had been sent to the scrap heap. This engine, William Buchanan's masterpiece, is now numbered 1086, and is still in service, hauling a local passenger train on the Pennsylvania division. It was built in 1893 and cost \$13,000. In the last 13 years it has made 13 visits to the shop for general repairs, which repairs cost \$14,253.

London's "Safety First" Council

LONDON.

England is making great efforts to stimulate interest in the "Safety First" movement, and has devised an essay competition for children of railway employees. The contest is open to boys and girls under 16 years of age either of whose parents is employed by a railway company and who resides within 20 miles of Charing Cross, London. The papers are to deal with the avoidance of accidents on railways. The prizes offered are: First £3 (approximately \$12), second £2 (approximately \$8), third £1 (approximately \$4), 14 prizes of ten shillings each (approximately \$2), and 28 prizes of 5 shillings each (approximately \$1).

St. Louis Railway Exposition

A unique and most successful exhibition of railway appliances was held at St. Louis, Mo., October 25-30. It was developed by a group of railroad officers, representatives of employees, railway supply men and influential citizens of St. Louis, to promote educational work along technical lines among railroad employees, and also to develop a spirit of fellowship and comradeship through the several programs.

Southern in Mississippi Changes Name

Official announcement was made last week that the name of the Southern Railway Company in Mississippi has been changed to the Columbus & Greenville Railroad Company. Hereafter the operations of the company will be carried on under the new name, but under the supervision of the same officers as heretofore.

Car Production—Nine Months' Figures

The production of freight and passenger cars for domestic service in September showed an increase over August. The passenger car deliveries were within one car of being as large as those for any two preceding months. The freight car deliveries were the largest for any month since February, although they were still on the low scale that has characterized this year's production to date. The figures, as reported to the Railway Car Manufacturers' Association by the 21 members of that organization and the two non-members co-operating with it in this matter, show deliveries in September of 3,529 freight and 38 passenger cars for domestic service; 1,088 freight cars for export, and freight car repairs amounting to 3,140.

American Railway Association Holds Annual Meeting

The Annual Session of the American Railway Association was held at the Blackstone, Chicago, on Wednesday, November 17, 1920, with R. H. Aishton, president of the association, in the chair. Announcement was made that the following were elected members of the board of directors by letter ballot: E. W. Beatty, president, Canadian Pacific; B. F. Bush, president, Missouri Pacific; W. R. Scott, president, Southern Pacific, Texas-Louisiana Lines; A. H. Smith, president, New York Central Lines; W. G. Besler, president and general manager, Central of New Jersey; W. H. Truesdale, president, D. L. & W.; E. J. Pearson, president, N. Y., N. H. & H.; J. H. Hustis, president, Boston & Maine; W. W. Atterbury, vice-president, Pennsylvania System; Daniel Willard,

president, Baltimore & Ohio; Hale Holden, president, Chicago, Burlington & Quincy; W. B. Storey, president, Atchison, Topeka & Santa Fe; H. E. Byram, president, Chicago, Milwaukee & St. Paul; C. H. Markham, president, Illinois Central; C. R. Gray, president, Union Pacific System; N. D. Maher, president, Norfolk & Western; W. L. Mapother, executive vice-president, Louisville & Nashville; H. G. Kelley, president, Grand Trunk.

The Power of Collective Bargaining

The national campaign committee of the sixteen railroad labor organizations addressed a letter to the members of the organizations, outlining instructions as to how to assist in the defeat for re-election of those members of Congress who voted for the transportation act, which contains the following characterization of the law:

"Adroitly phrased by railroad attorneys to achieve that purpose, the Cummins-Esch law destroys collective bargaining by railroad employees through their various crafts, and renders almost valueless protective agencies built up through years of struggle by employers' organizations. This is accomplished in part by the labor sections of the bill and in part by its guaranty provisions.

"The real power behind collective bargaining is the ability and right, when justice warrants, to cause the employer financial loss. Collective bargaining does not function against a guaranteed employer. No employer need fear financial loss occasioned by strikes or vacations of employees if the government or the people are required by law to make up the loss."

The "Best Friend of Charleston"

October marked the ninetieth anniversary of the landing of this historic locomotive in Charleston, S. C., the ship Niagara, bearing the engine from New York, having reached Charleston on October 23, 1830. The Southern Railway Company, in which system the pioneer railroad is now included, commemorates the event by a brief notice in its *News Bulletin* for September.

The "Best Friend" weighed about four or five tons; or, say, from one-fortieth to one-thirtieth the weight of a Southern Railway express locomotive of today.

The engine was built at the West Point foundry, New York, and the design is credited to Horatio Allen, who ran the Stourbridge Lion, the first locomotive that was ever moved on a track in America. Allen was chief engineer of the South Carolina Canal & Railroad Company. This railroad, extending from Charleston westward to Hamburg, S. C., opposite Augusta, Ga., was the first continuous 10 miles of railway in the world; the second railroad in the United States; the first to run a steam locomotive built in the United States for regular service, and the first in America built with the intention of using steam as motive power.

Metropolitan Section of American Welding Society

The newly formed Metropolitan section of the American Welding Society, at its first meeting on the afternoon of October 25 in the Engineering Societies building, elected the following officers: Chairman, H. A. Currie, assistant electrical engineer, New York Central Railroad; first vice-chairman, E. E. La Schaum, general superintendent motor equipment, American Railway Express Company; second vice-chairman, E. M. T. Rider, chief engineer, Third Avenue Railway Company; treasurer, W. E. Gray, Jr., New York sales manager, Elyria Enameled Products Company; secretary, Howard Odiorne, Submarine Boat Corporation.

Executive Committee

To serve for three years: H. G. Thompson, Transportation Engineering Corporation; William R. Hulbert, Metal & Thermit Corporation; E. J. Kingsbury, United Marine Contracting Corporation; J. C. O'Connell, Federal Shipbuilding Company.

To serve for two years: F. W. Smith, chief engineer, Oxweld Acetylene Company; A. E. Gaynor, J. A. Roebling's

Sons Company; Charles H. Haupt, Standard Oil Company; Charles P. Burr, G. M. Meurer Steel Barrel Company.

To serve for one year: R. W. Baker, Lincoln Electric Company; D. Ahldin, Commercial Acetylene Supply Company; M. W. Kellogg, M. W. Kellogg Company; Allen L. Price, Beckley Perforated Company.

Liquidation Staff of the U. S. R. A.

As indicating the extent of the work required to settle up the affairs of the Railroad Administration, which for 26 months had charge of the operation of the railroads, its staff of officers and employees on August 20 included 1,195 persons and its monthly payroll was \$250,576. Only a small reduction in force has been made during the period since the railroads were relinquished, although the staff is now only about half as large as it was immediately prior to the return of the roads. On March 1, according to a statement issued by Director General Hines, the force was reduced to 1,223 officers and employees, 1,420 having left the service of the central and regional administrations by March 1. In June, 1919, the total force was 2,725 and the monthly payroll was \$575,428. On February 20, 1920, it was 2,612 and the monthly payroll was \$570,078.

Shop Construction

CORNWALL.—This company has awarded a contract to the Austin Company, Cleveland, Ohio, for the construction of a machine and locomotive erecting shop at Lebanon, Pa. The new building will be of reinforced concrete, brick and steel construction. The dimensions will be 140 ft. by 180 ft. and 50 ft. high. The cost is estimated at approximately \$160,000.

GULF COAST LINES.—This company is constructing temporary buildings at Kingsville, Tex., to replace the machine shops which were destroyed by fire, pending the completion of plans for permanent shop facilities.

MISSOURI PACIFIC.—This company has awarded a contract to Joseph E. Nelson & Sons, Chicago, for the construction of a power plant at Dupou, Ill., to cost approximately \$15,000.

ST. LOUIS-SAN FRANCISCO.—This company has awarded a contract to the William McDonald Construction Company, St. Louis, Mo., for the construction of a roundhouse and machine shop at Dublin, Tex. The Frisco has also awarded contracts to the Hedges-Weeks Construction Company, Springfield, Mo., for the setting of a new turntable, and the construction of cinder conveyors and materials racks at Dublin. An addition to the car repair shop of this company at Fort Scott, Kan., is being built by the T. S. Leake Construction Company, Chicago, at a cost of about \$15,000.

SOUTHERN.—This company is building a brass foundry at its Lenoir Car Works, Lenoir City, Tenn., which will cost approximately \$30,000. The building will be one story, 62 ft. by 120 ft., of brick and concrete construction. This addition to the plant will involve the purchase of five revolving furnaces, a metal separator and a journal bearing boring machine.

SOUTHERN PACIFIC.—This company will construct the following buildings at Sacramento, Cal.: A reinforced concrete oil and paint house, 65 ft. by 100 ft.; a store building of mill construction with corrugated iron sides, and concrete foundation, 500 ft. long and 60 ft. wide, and a planing mill of mill construction, with corrugated iron sides and roof, to be 126 ft. wide and 360 ft. long.

Reduction of Forces

Reductions of railroad forces by the dismissal of considerable numbers of men on short notice, particularly in shops, has been reported recently from many places. The Pennsylvania Railroad, in dismissing 1,350 men at the Altoona shops, about 15 per cent of the total force, giving the men five days' notice, announced that this was to be deemed a permanent reduction in force, not a temporary lay-off. This move was made necessary by a reduction in the volume of repair work and affected all departments except the iron and brass foundries. About 1,500 employees were dismissed from shops on the Central Pennsylvania division of the road and 1,000 on the Philadelphia division. The New York Central dismissed 500 men at West Albany, four-fifths of these being shop men. The Boston & Albany has dismissed about ten

per cent of the forces in its principal shops. The New York, New Haven & Hartford has dismissed considerable numbers of men in various departments. Certain shops of the Baltimore & Ohio report dismissals of ten per cent of the employees.

Recent Locomotive Orders

NATIONAL RAILWAYS OF MEXICO.—Florian & Co., Ltd., importers and exporters, 52 Wall street, New York, confirm the report that they have closed a contract with the Mexican government for the delivery of \$20,000,000 of railroad equipment and material. The negotiations were completed in Mexico City and the contract is signed by the Minister of Railways and the National Railways of Mexico. The contract calls for the delivery of locomotives, cars and material for section houses. Certain credits have been extended to Mexico in this connection which are properly secured; all financial arrangements in connection with this contract have been completed. Florian & Co., Ltd., further confirm the report that the purchase of the equipment will be made through their New York office.

Freight Car Orders

THE NATIONAL RAILWAYS OF MEXICO has ordered 100 tank cars of 12,000 gallons capacity from the American Car & Foundry Company.

MEETINGS AND CONVENTIONS

The following list gives names of secretaries, dates of next or regular meetings and places of meeting of mechanical associations and railroad clubs:

- AIR-BRAKE ASSOCIATION.**—F. M. Nellis, Room 3014, 165 Broadway, New York City.
- AMERICAN RAILWAY ASSOCIATION, DIVISION V—MECHANICAL.**—V. R. Hawthorne, 431 South Dearborn St., Chicago.
- DIVISION V.—EQUIPMENT PAINTING DIVISION.**—V. R. Hawthorne, Chicago.
- AMERICAN RAILWAY ASSOCIATION, DIVISION VI.—PURCHASES AND STORES.**—J. P. Murphy, N. Y. C., Collinwood, Ohio.
- AMERICAN RAILROAD MASTER TINNERS', COPPERSMITHS' AND PIPEFITTERS' ASSOCIATION.**—C. Borchardt, 202 North Hamlin Ave., Chicago.
- AMERICAN RAILWAY TOOL FOREMEN'S ASSOCIATION.**—R. D. Fletcher, 1145 E. Marquette Road, Chicago.
- AMERICAN SOCIETY FOR TESTING MATERIALS.**—C. L. Warwick, University of Pennsylvania, Philadelphia, Pa.
- AMERICAN SOCIETY OF MECHANICAL ENGINEERS.**—Calvin W. Rice, 29 W. Thirty-ninth St., New York.
- AMERICAN SOCIETY FOR STEEL TREATING.**—W. H. Eisenman, 154 E. Erie St., Chicago.
- ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.**—Joseph A. Andreucetti, C. & N. W., Room 411 C. & N. W. Station, Chicago.
- CANADIAN RAILWAY CLUB.**—W. A. Booth, 131 Charron St., Montreal, Que. Next meeting December 14. Paper on The Every Day Duties of a Roadmaster will be presented by E. Keough, assistant engineer of maintenance of way, Canadian Pacific Railway, Montreal. Illustrated by stereopticon views.
- CAR FOREMEN'S ASSOCIATION OF CHICAGO.**—Aaron Kline, 626 N. Pine Ave., Chicago. Meeting second Monday in month, except June, July and August, New Morrison Hotel, Chicago.
- CAR FOREMEN'S ASSOCIATION OF ST. LOUIS.**—Thomas B. Koenek, 604 Federal Reserve Bank Building, St. Louis, Mo. Meetings first Tuesday in month at the American Hotel Annex, St. Louis.
- CENTRAL RAILWAY CLUB.**—H. D. Vought, 95 Liberty St., New York. Meetings second Thursday in January, March, May, September and November, Iroquois Hotel, Buffalo, N. Y.
- CHIEF INTERCHANGE CAR INSPECTORS' AND CAR FOREMEN'S ASSOCIATION.**—W. P. Elliott, T. R. R. A. of St. Louis, East St. Louis, Ill.
- CINCINNATI RAILWAY CLUB.**—W. C. Cooder, Union Central Building, Cincinnati, Ohio. Meetings second Tuesday in February, May, September and November, Hotel Sinton, Cincinnati, Ohio.
- DIXIE AIR BRAKE CLUB.**—E. F. O'Connor, 10 West Grace St., Richmond, Va.
- INTERNATIONAL RAILROAD MASTER BLACKSMITHS' ASSOCIATION.**—W. J. Mayer, Michigan Central, 715 Clarke Ave., Detroit, Mich.
- INTERNATIONAL RAILWAY FUEL ASSOCIATION.**—J. G. Crawford, 702 East 51st St., Chicago.
- INTERNATIONAL RAILWAY GENERAL FOREMEN'S ASSOCIATION.**—William Hall, 1061 W. Wabasha Ave., Winona, Minn.
- MASTER BOILERMAKERS' ASSOCIATION.**—Harry D. Vought, 95 Liberty St., New York. Convention May 23 to 26, 1921, inclusive, Planters' Hotel, St. Louis, Mo.
- NEW ENGLAND RAILROAD CLUB.**—W. E. Cade, Jr., 683 Atlantic Ave., Boston, Mass. Next meeting December 14. Paper on Some Phases of Railway Operations in Canada will be presented by Grant Hall, vice-president, Canadian Pacific Railway Company.
- NEW YORK RAILROAD CLUB.**—H. D. Vought, 95 Liberty St., New York. Second annual dinner, Hotel Commodore, New York, Thursday, December 16, at 6:30 p. m.
- NIAGARA FRONTIER CAR MEN'S ASSOCIATION.**—George A. J. Hochgrebe, 623 Brisbane Building, Buffalo, N. Y. Regular meetings January, March, May, September and October.
- PACIFIC RAILWAY CLUB.**—W. S. Wollner, 64 Pine St., San Francisco, Cal. Meetings second Thursday in month, alternately in San Francisco and Oakland, Cal.
- RAILWAY CLUB OF PITTSBURGH.**—J. D. Conway, 515 Grandview Ave., Pittsburgh, Pa. Meetings fourth Thursday in month except June, July and August, American Club House, Pittsburgh.
- ST. LOUIS RAILWAY CLUB.**—B. W. Frauenthal, Union Station, St. Louis, Mo.
- TRAVELLING ENGINEERS' ASSOCIATION.**—W. O. Thompson, N. Y. C. R. R., Meetings second Friday in month except June, July and August. Buffalo, N. Y.
- WESTERN RAILWAY CLUB.**—Bruce V. Crandall, Chicago. Meetings third Monday in month except June, July and August.

PERSONAL MENTION

GENERAL

C. E. BINGHAM has been appointed supervisor of mechanical examinations of the Michigan Central, with headquarters at Detroit, Mich.

J. HERRON has been appointed acting superintendent of motive power of the Duluth, South Shore & Atlantic, with headquarters at Marquette, Mich., succeeding J. J. Conolly, granted leave of absence.

CHARLES A. NELSON, formerly senior mechanical engineer, Bureau of Valuation, Interstate Commerce Commission, has returned to the mechanical engineer's office of the Delaware & Hudson at Watervliet, N. Y.

D. M. PEARSALL, superintendent of motive power of the Atlantic Coast Line, second and third divisions, with headquarters at Waycross, Ga., has been transferred as superintendent of motive power, first division, with headquarters at Rocky Mount, N. C. J. E. Brogdon, shop superintendent at Waycross, Ga., has been appointed superintendent of motive power, second and third divisions, with the same headquarters, succeeding Mr. Pearsall. F. P. Howell, master mechanic at Savannah, Ga., has succeeded Mr. Brogdon as shop superintendent at Waycross, and J. W. Reams has been appointed master mechanic at Savannah, succeeding Mr. Howell.

MASTER MECHANICS AND ROAD FOREMEN OF ENGINES

EDWARD FRANCE has been appointed road foreman of locomotives of the Mohawk division of the New York Central with headquarters in Rensselaer, N. Y.

S. J. KELLEY has been appointed master mechanic of the Erie, with headquarters at Hornell, N. Y. This appointment is the result of the division of the territory of C. H. Norton, who remains master mechanic of the Susquehanna and Tioga divisions, but relinquishes the Allegheny and Bradford divisions to Mr. Kelley.

C. J. QUANTIC, master mechanic of the Canadian National at Port Mann, B. C., has been transferred to Vancouver and given jurisdiction over all lines west of and not including Edmonton, Alta. A. H. Mahan, district master mechanic of the Grand Trunk Pacific at Edson, Alta, has been appointed assistant master mechanic of the Canadian National and the Grand Trunk Pacific, with the same headquarters. Mr. Mahan will have jurisdiction over the lines from Edmonton, Alta., to McBride, B. C., and from Edson, Alta., to Mountain Park, Alta. A. Walts, district master mechanic of the Grand Trunk Pacific, with headquarters at Smithers, B. C., has been appointed assistant master mechanic of the Canadian National and the Grand Trunk Pacific, with the same headquarters. His jurisdiction will include all lines from McBride, B. C., to Prince Rupert.

CAR DEPARTMENT

A. H. EAGER has been appointed general superintendent of rolling stock on the Canadian National and Grand Trunk Pacific, with headquarters at Winnipeg, Man. Mr. Eager was born on July 15, 1868, at Waterloo, Que., and entered railroad service in June, 1885, as a machinist apprentice in the shops of the South-eastern, at Farnham, Que. After a short time he left the service of this road to enter the shops of the Canadian Pacific, at Farnham, and was made a machinist in 1893. After serving as machinist for six years, he was made locomotive shop foreman and served in this capacity until 1901, when he was promoted to locomotive foreman, at Megantic, Que. In 1903, he was transferred to Cranbrook, B. C., where he was employed until May, 1906, when he was promoted to general foreman, with headquarters at Calgary, Alta. From 1907 to 1910, Mr. Eager served successively as district master mechanic, with headquarters at Kenora, Ont., and as locomotive foreman at Calgary, Alta. In 1910, he entered the service of the Canadian National, as superintendent of shops, with headquarters at Winnipeg, Man., a position which he held until August, 1916, when he was promoted to assistant superintendent

of rolling stock of the Western lines of the Canadian National. At the time of his recent appointment, Mr. Eager was mechanical superintendent of the Canadian National, with headquarters at Winnipeg, a position to which he had been promoted in December, 1918. The office of mechanical superintendent has been abolished.

SHOP AND ENGINEHOUSE

C. W. ADAMS, general foreman of locomotives on the Michigan Central, with headquarters at St. Thomas, Ont., has been promoted to superintendent of shops, with jurisdiction over the locomotive department, and with headquarters at Jackson, Mich., succeeding W. C. Bell, who has been transferred to Bay City, Mich.

P. J. FLYNN, general roundhouse foreman of the Erie at Hornell, N. Y., has accepted a position in the Lehigh Valley shops at Pittston, Pa., as general foreman.

I. W. HICOK, erecting shop foreman on the Chicago & Alton, with headquarters at Bloomington, Ill., has been promoted to superintendent of shops, with the same headquarters, succeeding J. J. Carey. William Monroe succeeds Mr. Hicok.

PURCHASING AND STOREKEEPING

B. B. BRAIN, fuel agent of the Kansas City Southern, with headquarters at Kansas City, Mo., has been appointed purchasing agent, succeeding G. W. Bichlmeir, resigned to accept service with another company.

F. S. HAMMOND, general storekeeper of the Pittsburgh, Shawmut & Northern, has been appointed purchasing agent in addition to his other duties.

G. H. WALDER, assistant purchasing agent of the Chicago, Milwaukee & St. Paul, with headquarters at Chicago, has been promoted to purchasing agent, succeeding W. A. Linn, who has been assigned to other duties.

OBITUARY

C. C. HIGGINS, superintendent of motive power of the St. Louis-San Francisco, was killed at Racine, Mo., the night of November 3, when a freight train crushed into his private car.

Mr. Higgins was born at Aurora, Ill. He graduated from the mechanical engineering department of the University of Minnesota in 1900, and immediately entered railroad work as a special apprentice in the service of the Chicago, Burlington & Quincy. After five years with that road, during which he served successively as assistant in the laboratory, roundhouse foreman and general roundhouse foreman at various points on the line, he left to become associated with the American Brake Shoe & Foundry Co., in its Chicago office. During

C. C. Higgins

the next four years he served as sales engineer and salesman with this company. In 1909, however, he returned to railroad service, accepting an appointment with the Atchison, Topeka & Santa Fe, with headquarters at Topeka, Kan., where he was assigned to special work in connection with the motor schedules of the mechanical department. In 1912 he was engaged by J. W. Kendrick, consulting railway engineer, Chicago, to make reports on various railroads in connection with the valuation and rehabilitation of their properties. When the position of assistant to the vice-president of the St. Louis-San Francisco was created on March 15, 1918, Mr. Higgins was appointed to that position. He was made superintendent of motive power on March 1, 1920, the position he held at the time of his death.

SUPPLY TRADE NOTES

F. M. Whyte, vice-president, with office at New York, of the Hutchins Car Roofing Company, Detroit, Mich., has resigned.

The Colburn Machine Tool Company has removed its entire business from Franklin, Pa., to its new plant at 1038 Ivanhoe road, Cleveland, Ohio.

W. A. Ruth, who recently resigned from the sales force of the National Car Coupler Company, has become affiliated with the Superior Steel Castings Company, Benton Harbor, Mich.

G. Schrimmer has resigned as sales engineer in the Detroit office of the Whiting Foundry Equipment Company, Whiting, Ill., and is now associated with W. C. Bennett, industrial engineer, Chicago.

Albert E. Newton, vice-president and general manager of the Reed-Prentice Company, has resigned. He will, however, remain with the Reed-Prentice Company in an advisory and consulting capacity until 1922.

D. J. Crowley has been appointed Michigan sales agent of the Tacony Steel Company, Philadelphia, Pa. Mr. Crowley's office is in the Dime Bank building, Detroit, Mich. D. B. Carson has been appointed Cleveland district sales manager.

G. E. Anderson, assistant eastern sales manager of the Duff Manufacturing Company, Pittsburgh, has been promoted to southwestern sales manager and placed in charge of the new branch office located in the Railway Exchange Building, St. Louis, Mo.

Joseph Markham, formerly railway sales representative of the E. I. Du Pont de Nemours & Co., Inc., has been appointed sales agent of the Pressed Steel Car Company and the Western Steel Car & Foundry Company, with an office in the Peoples Gas building, Chicago.

W. H. DeWolfe recently has been appointed district manager of the New Britain Machine Co., with headquarters at Room 638, Old South building, 294 Washington street, Boston. Mr. DeWolfe formerly was connected with the Philadelphia office of this company.

The Blaw-Knox Company, Pittsburgh, Pa., has established a new sales district in the South, with headquarters at Birmingham, Ala. Prescott V. Kelly, formerly connected with the executive sales department at Pittsburgh, is in charge of this office, which is located in the American Trust building.

C. F. Meyer, assistant secretary of the Landis Machine Company, Waynesboro, Pa., will leave shortly for an extended trip to the Orient in the interests of his company. Mr. Meyer will visit England, India, the Dutch East Indies, Australia, the Philippine Islands, China, Japan and the Hawaiian Islands.

Anton Becker, assistant to president of the Ralston Steel Car Company, Columbus, Ohio, has been elected vice-president to succeed F. E. Symons, who has been elected president. The other officers of the company are F. A. Livingston, secretary and treasurer, and L. C. Roy, assistant secretary and assistant treasurer.

Frederick T. Davis, formerly with the Davidson Tool & Manufacturing Corporation, is now connected with the New York branch office of the Reed-Prentice Company, the Becker Milling Machine Company and the Whitcomb-Blaisdell Machine Tool Company, located at Grand Central Palace, New York city.

The Chicago Pneumatic Tool Company announces the removal of its rock drill plant from 864 East Seventy-second street, Cleveland, Ohio, to its Boyer pneumatic hammer plant at 1301 Second boulevard, Detroit, Mich. The company's Little Giant air drill plant still remains at 1241 East Forty-ninth street, Cleveland.

R. G. Barrington, formerly connected with the Cleveland Twist Drill Company, Cleveland, Ohio, has been appointed Cleveland sales manager for the Reed-Prentice Company, the Becker Milling Company and the Whitcomb-Blaisdell Machine Tool Company, with headquarters at 408 Frankfort avenue, Cleveland, Ohio.

L. R. Fedler has been appointed district manager for the Keller Pneumatic Tool Company in the Milwaukee district, with offices at 915 Majestic building, Milwaukee. For the past twelve years, Mr. Fedler has been associated with the sales organization of the Chicago Pneumatic Tool Company in the Milwaukee territory.

The Howard N. Potts medal, which is awarded for distinguished work in science and mechanical arts by the Franklin Institute, was presented on October 20 to E. P. Bullard, Jr., president of the Bullard Machine Tool Co., Bridgeport, Conn., for his work in connection with the development of automatic machinery in the metal-cutting field.

A new policy of direct selling for all three companies has been established, under the charge and control of John P. Ilsley, formerly general manager of the Becker Milling Machine Company's plant. Branch sales offices have been established in the leading cities of the United States and a foreign sales manager has been employed for Europe.

Alfred J. Babcock, president of Manning, Maxwell & Moore, Inc., New York, who retired in May, 1920, on account of ill-health, died on October 30, in London, England, after a short illness. He was born at Brookfield, N. Y., in 1850, and served in the United States Army from 1867 to 1871. He took a law course at Ann Arbor, and practiced law in Denver, Colo., from 1882 to 1884. Mr. Babcock entered the machinery business in Chicago with the Fay & Egan Company and later entered the employ of Manning, Maxwell & Moore, Inc., at Chicago, as manager of that branch. About seven years ago he came to New York as assistant to president, and later was made president. He retired from active service in May, 1920, on account of continued ill health.

A. J. Babcock

The name of the selling organization which C. C. Bradford recently formed, has been changed from the Manufacturers' Sales Company, to the Bradford Sales Company. The offices of this company, which will represent not more than two manufacturers as a district sales office of each, are located at 340 Leader-News building, Cleveland, Ohio.

C. E. Hildreth has offered to resign as president of the Whitcomb-Blaisdell Machine Tool Company, in view of the consolidation in management. He has been requested, however, to allow the situation to remain in statu quo, which he has consented to do, pending the working out of the plan for centralizing the management of the different plants.

Steps have been taken to centralize the production and manufacturing departments, and F. O. Hoagland, until recently vice-president and general manager of the Bilton Machine Tool Company, Bridgeport, Conn., has taken the position of general manager of the Reed-Prentice Company, the Becker Milling Machine Company and the Whitcomb-Blaisdell Machine Tool Company.

A. H. Tuechter, president of the Cincinnati-Bickford Tool Company, Oakley, Cincinnati, Ohio, was elected president of the National Machine Tool Builders' Association, at its

annual meeting at the Hotel Astor, New York. Mr. Tuechter has served that organization as second vice-president, and at one time was a member of the joint general committee of the American Society of Mechanical Engineers.

Under the name of Midgley & Borrowdale, a partnership, with headquarters in the McCormick building, Chicago, has been formed by S. W. Midgley and J. M. Borrowdale, both of whom were formerly connected with the Liberty Steel Products Company, to deal in railway supplies. A contract has already been closed with the Superior Steel Castings Company, Benton Harbor, Mich., manufacturers of steel and malleable iron castings, for the exclusive railway sales of the company's products, and the partners are also western sales representatives of the Pneumatic Safety Valve Company, Woonsocket, R. I., manufacturers of safety air valves for pneumatic tools; the Henry Giessel Company, Chicago, manufacturers of sanitary filters and water coolers for passenger cars and locomotives, and the Trumbull Waste Company, Philadelphia, Pa.

S. W. Midgley

S. W. Midgley entered railroad service in 1898, in the office of the Car Mileage Bureau. In 1902, he entered the railway supply business as general sales representative of the National Car Coupler Company, remaining with this company until late in 1907. He then became connected with the Curtain Supply Company as western sales representative, later becoming western sales manager. In 1911 he left the Curtain Supply Company to enter the service of the Acme Supply Company as general sales manager, remaining in the service of this company until January 1, 1918. He then became district manager of the Chicago office of the Liberty Steel Products Company and remained with that company until the closing of its Chicago office, September 30, 1920.

J. M. Borrowdale began railroad service in 1890, with the Fitchburg Railroad, at Boston, Mass. In 1893 he came to Chicago to enter the employ of the Chicago, New York & Boston Refrigerator Company as a car builder. He remained with this company until 1896, when he left to enter the Burnside shops of the Illinois Central. Here he served successively as a car builder, foreman, and general foreman, until 1909, when he was appointed superintendent of the car department of that road. In 1917, he left railway service to join the sales force of the H. W. Johns-Manville Company, and two years later went with the Liberty Steel Products Company, with which company he remained until the Chicago office was closed, September 30, 1920.

J. M. Borrowdale

E. P. Williams, formerly with McJunkin Advertising Agency, and later director of field work, Bureau of Market Analysis, Inc., has joined the staff of the Independent Pneumatic Tool Company, manufacturers of Thor air and electric tools. Mr. Williams will be located in Chicago.

The Reed-Prentice Company, the Becker Milling Machine Company and the Whitcomb-Blaisdell Machine Tool Company, which are largely owned and controlled by the same interests, have decided, for the purpose of efficiency, to consolidate still further the operating management of all three plants, with the result that a centralized executive office has been established at 53 Franklin street, Boston, Mass., under the direction of Arthur H. Weed, president.

The Graver Corporation, East Chicago, Ind., manufacturers of steel tanks and general plate construction, oil refinery equipment, water softening and purifying equipment, announces the opening of branch offices in the following cities: New York, 280 Broadway; Pittsburgh, Pa., 62 Conestoga building; Kansas City, Mo., 1001 Gloyd building; Cincinnati, Ohio, 220 Gwynne building; Toledo, Ohio, 314 Nicholas building, and San Francisco, Cal., 312 Balboa building.

Donald S. Barrows, chief engineer and works manager of The T. H. Symington Company, New York, since 1917, with headquarters at Rochester, N. Y., has been elected vice-president in charge of operations. He was born at New Haven, Conn., in 1877, and graduated from the New York Law School in 1898 and was admitted to the bar in New York State in 1899. Following his entry into the engineering field and previous to his association with the Symington organization Mr. Barrows held the following positions: Chief engineer of the North Penn Iron Company, Philadelphia, Pa.; chief engineer of the Insley Iron Works, Indianapolis, Ind.; mechanical engineer of the Wigham-Magor Car & Manufacturing Company, and mechanical engineer with the American Car & Foundry Company, at New York. Mr. Barrows entered the service of The T. H. Symington Company in 1915, and as chief engineer had charge of all engineering matters in connection with the Symington railway products as well as the planning, enlargement and execution of extensive plant improvements. In 1917 he was promoted from the position of chief engineer to chief engineer and works manager, and now becomes vice-president in charge of operations. In the development of the Symington company's extensive railway business at Rochester to its present state of efficiency in quality and quantity production Mr. Barrows has been largely responsible.

D. S. Barrows

Fairbanks, Morse & Co., Chicago, have bought the entire business consisting of all stock on hand, good-will and liabilities of the Luster Machine Shop & Railway Equipment Company, 917 Arch street, Philadelphia, Pa. Fairbanks-Morse have opened a new branch at this address under the management of D. W. Dunn, and will sell its complete line of engines, motors, pumps, etc. The entire personnel of the Luster Machinery Co. has been retained. E. J. Luster, former president, will be manager of the machine tool division of the Fairbanks-Morse Philadelphia branch.

L. C. Wilson, for the past two years general sales manager of the Chain Belt Company, Milwaukee, Wis., has been elected secretary of the Federal Malleable Company, West Allis, Wis., manufacturers of malleable castings, malleable chain and the Rapid molding machine. Mr. Wilson, after graduating from Yale University, began his business career as a salesman with Harbison-Walker Refractories Company, Pittsburgh. In 1917 he became associated with the Chain Belt Company and served as assistant to the vice-president until his appointment as sales manager. Clifford F. Messenger, who is also a graduate of Yale University, and has been

with the Chain Belt Company since 1909 in various capacities, including that of advertising manager, manager of Rex concrete mixer sales and assistant to the vice-president, has been appointed sales manager of the Chain Belt Company, to succeed Mr. Wilson.

The Morse Chain Company, Ithaca, N. Y., has established a branch factory in Detroit which will be devoted exclusively to the manufacture of silent chain sprockets and the Morse adjustment for use in automobile power transmissions. The manufacture of chains and power transmission at the main plant at Ithaca will continue. The Detroit branch will be under the general management of F. C. Thompson, with F. M. Hawley as chief engineer, and C. B. Mitchell as factory manager. The sales and engineering offices are located at the Detroit plant, Eighth and Abbott streets.

Arthur E. Hauck, president of the Hauck Manufacturing Company, makers of oil burning appliances, kerosene torches, furnaces and forges, Brooklyn, N. Y., died at his home in that city on October 30, at the age of 41. He was born in Germany, where he learned the trade of coppersmith. At the age of 20 he came to America and in 1902 began business in Brooklyn. He was the inventor of a number of appliances for burning oil, one of which was the method of vaporizing kerosene in a torch with proportioned heat-resisting nozzle, the form of vaporization which is used to reduce carbonization to a minimum.

The J. B. Engineering Sales Company, 60 Prospect street, Hartford, Conn., has been appointed Connecticut sales agent of the Conveyors Corporation of America, formerly the American Steam Conveyor Corporation. The J. B. Engineering Sales Company is owned by John Breslau, who is a graduate of the Sheffield Scientific School, Yale University, and was formerly sales engineer, manager of publicity and production manager of the Terry Steam Turbine Company. The J. B. Engineering Sales Company is sales agent also for the Griscom Russell Company and the Terry Steam Turbine Company, in Connecticut.

J. B. Webb has been appointed western representative of the Diamond Specialty & Supply Company, Philadelphia, Pa. Mr. Webb has, for many years, been manager of the railway supply department of the Simmons Hardware Company, and in that capacity handled the products of the Diamond Specialty & Supply Company, including water gage glasses, lubricator glasses, Watertown automatic cylinder cocks, Steinbrunn boring bars and other devices. Through this new arrangement he will sell these goods to the railroads operating out of Chicago and west of the Mississippi river. Mr. Webb's headquarters are at 713 Chestnut street, St. Louis, Mo.

John A. Talty, assistant superintendent of equipment and equipment inspector for the New York Public Service Commission, Second district, has taken a position as special engineer with the Franklin Railway Supply Company, New York. Mr. Talty began railway work in 1883 as freight brakeman on the Erie Railroad. He consecutively served as foreman and locomotive engineman on that road and then as air brake instructor on the Westinghouse air brake instruction car on the Erie. Later he took a similar position with the Scranton Correspondence School. From 1900 to 1910 he served as road foreman of engines on the Delaware, Lackawanna & Western. In the latter year he joined the force of the public service commission as assistant supervisor of equipment and equipment inspector, inspecting locomotives and cars and investigating accidents, and he now leaves that position to go to the Franklin Railway Supply Company.

The Landis Machine Company, Waynesboro, Pa., has just completed a new addition to its shop, which will be the main machine shop. This new building is 308 ft. long by 146 ft. wide. Nearly 365 tons of steel were used in the construction, which was under the direction of A. R. Warner. The building is modern in every respect, being provided with the best of heating and lighting arrangements. A five-ton crane with a span of 66 ft. operates the entire length of the building and will provide means for moving heavy castings. On October 30 the company gave a house warming party in the new shop to Landis employees and their families. Approximately 1,400 guests attended and enjoyed the

good things arranged for them. Addresses were made by J. C. Benedict, general manager, and S. F. Newman, assistant general manager of the Landis Machine Company. The party was concluded in the evening by a special entertainment, after which the employees presented to the management a set of resolutions expressing thanks and appreciation for the good time afforded and opportunity for closer fellowship.

F. Hopper has resigned as division master mechanic of the Chicago, Milwaukee & St. Paul to accept a position with the Standard Stoker Company, Inc., as works superintendent at Erie, Pa. Mr. Hopper has been in constant railway service since 1893. He served his apprenticeship as machinist at the old W. T. Garratt Machine Company, San Francisco, Cal., and from 1889 to 1890 was in the marine service of the Pacific Mail Steamship Company. He then went to China as a mechanic. Later he became a mechanic and locomotive foreman on the Guatemala Central. He then entered the service of the Edison Light Company, Napa City, Cal., as an electrician and chief engineer. From 1893 to 1897, he served as a fireman on the Southern Pacific, when he was promoted to locomotive engineer. Resigning this position, he entered the employ of the Chicago, Rock Island & Pacific as road foreman of equipment. In 1911 he was promoted to master mechanic; in 1913 resigned to accept a position as master mechanic on the D. W. & P. Railway, which is controlled and owned by the Canadian Northern, and in 1919 entered the employ of the Chicago, Milwaukee & St. Paul.

S. T. Callaway, of the firm of Callaway, Fish & Co., New York, and his associates have acquired a substantial interest in and are financing the Elvin Mechanical Stoker Company, and Mr. Callaway has been elected president of the company. A. G. Elvin, the inventor of the Elvin mechanical stoker, who is largely interested in the company, has been elected vice-president and treasurer. Mr. Elvin is also the inventor of the Elvin driving box lubricator, the Franklin grate shaker and the Franklin fire door, and other successful economy producing devices in the steam locomotive specialty field. S. T. Whitaker, of the law firm of Hardy, Stancliffe & Whitaker, attorneys for the company, has been elected secretary. The directorate of the company includes the officers as mentioned above, and E. M. Richardson, of the Sherwin-Williams Company. A long term contract has been entered into with the American Locomotive Company, under which the stoker will be manufactured for this company by the American Locomotive Company, at its Schenectady works, thereby enabling the company to accept immediately contracts in quantity for stokers.

Hugh Pattison has joined the staff of the heavy traction railway department of the Westinghouse Electric & Manufacturing Company to make special engineering studies under the direction of F. H. Shepard, director of heavy traction. Mr. Pattison was graduated from the Johns Hopkins University, electrical engineering course, in 1892. His first position was that of foreman electrician of the Norfolk, Va., Navy Yards, wiring and installing electric apparatus on naval vessels. In 1893 he became assistant engineer with Sprague, Duncan & Hutchinson, consulting engineers at Baltimore. From 1894 to 1903 he was associated as engineering assistant to Frank J. Sprague, vice-president and technical director of the Sprague Electric Company in New York and assisted in equipping and operating multiple unit control on the Boston Elevated and in Brooklyn. In 1905 Mr. Pattison joined Westinghouse, Church, Kerr & Company as an engineer. From 1905 to 1911, during the electrification of the Pennsylvania tunnel into New York, Mr. Pattison was assistant engineer of electric traction for George Gibbs, consulting engineer. Later Mr. Pattison had charge of the electrification of the West Jersey & Seashore Railroad from Camden to Atlantic City. He also built an experimental single-phase electric railway on the Long Island Railroad and had charge of the conduct of locomotive tests on the West Jersey & Seashore Railroad to determine the effect on track. In 1911 he was appointed engineer in charge of the Chicago Association of Commerce Committee in the study of smoke abatement and the electrification of terminal railways in Chicago. During the war Mr. Pattison was appointed assistant to general manager of the Remington Arms Company.

The Precision & Thread Grinder Manufacturing Company, manufacturers of the multi-graduated precision grinder, have moved their offices to 1 South Twenty-first street, Philadelphia, Pa. At this new location they will maintain a machinery display department, showing in addition to their grinders, the Craley master tool maker, Miller radius and angle wheel dressers for tool room and production work, the Herrmann snap thread gages, and other tools and accessories.

TRADE PUBLICATIONS

LOCOMOTIVES.—The general dimensions and illustrations of various types of eight-coupled locomotives for freight service and locomotives for heavy passenger service are given in two illustrated books, Records No. 98 and 99, issued by the Baldwin Locomotive Works, Philadelphia, Pa.

AJAX METAL PRODUCTS.—A new 38-page, illustrated export catalogue has been issued in two editions—one English, and one Spanish—by the Ajax Metal Company, Philadelphia. This book is mainly devoted to a complete listing of Ajax products, with a detailed account of their uses in the various industries.

FOUNDRY EQUIPMENT.—In Bulletin No. 154, issued by the Whiting Foundry Equipment Company, Harvey, Ill., are described and illustrated complete layouts and equipment for gray iron, steel, brass, car wheel and malleable iron foundries. The bulletin contains a large number of illustrations taken in Whiting equipped plants.

WOOD PRESERVATION.—Two folders recently issued by the Barrett Company give information regarding the preservation of timber by the use of refined creosote. One entitled "Preserving Wood Roof Decks with Carbosota" describes the surface treatments recommended for lumber used in roof construction. The second, entitled "Longer Life for Mine Timbers," discusses the selection and treatment of timber, not only for mine bracing but also for cars and buildings subject to decay.

MALLEABLE CASTINGS.—The American Malleable Castings Association has published a chart which is designed to show the present status of the malleable iron industry. The chart gives a graphical representation of the castings shipped by the member firms as compared with the capacity of the foundries. The association points out that it is expected that the tonnage of unfilled orders will be reduced in the near future and better deliveries will be made than have been possible since 1915.

PORTABLE ELECTRIC DRILLS.—The complete line of electric air compressors, portable electric drills and electric valve grinders made by the Black & Decker Manufacturing Company, Baltimore, Md., is described in Catalogue No. 2, recently issued by this company. The booklet includes descriptions of compressors of various capacities, electric drills for drilling holes up to $\frac{3}{8}$ in. and reaming up to $\frac{7}{16}$ in. in steel. The mechanical and electrical features of the equipment are quite fully described and the construction is shown by sectional views.

FIRE BRICK BOND.—"Hytempite in the Gas Plant" is the title of a bulletin issued recently by the Quigley Furnace Specialties Company, New York. According to the bulletin, Hytempite is a highly refractory plastic material, scientifically compounded, for bonding fire bricks and for kindred uses. The importance of this bond in the construction and maintenance of gas producers is particularly emphasized in the bulletin, but it can be used in railway shop or other industrial furnaces and boiler settings. Illustrations of this fire brick bond in emergency repairs are shown.

PIPE VALVES, FITTINGS AND TOOLS.—An attractive and unusual catalogue is the book recently published by the Walworth Manufacturing Company, Boston, Mass., for its export business. The extensive line of fittings, valves, boiler and engine accessories, and tools which this company produces is illustrated, descriptions being given in English, French, Spanish and Portuguese. Valuable engineering information is included such as the amount of expansion cared for by bends in wrought iron or steel pipe and conversion tables for English, metric and Latin units, etc. A comprehensive index in each of the four languages facilitates locating the equipment listed.

Development of a Transportation Element

Westinghouse blazed a broad trail into the wilderness of railroad transportation when, 51 years ago, he invented the Straight Air Brake. At a single stroke he gave to railroads shorter train stops, higher train speeds and safe control of moving trains. Railroads seized these benefits, advanced and expanded.

He and his staff of experts, representing

a collective judgment of many years and varied practical experience, developed in a high degree the sagacity and foresight necessary to unflinchingly interpret the needs of a growing transportation, and provided at each step of a continuous development the braking requirements of a railroad transportation system now acknowledged to be the best in the world.

30 of these Light Mountain type, 4-8-2 engines have been bought by the New Haven road, and all are equipped with Duplex Stokers.

Duplex Stoker, complete, showing conveyor trough, screw, crusher, driving engine, transfer hopper and elevators.

Duplex Stoker an Integral Part of the Modern Locomotive

Thirty of the above type of engine, all Stoker-fired, are pulling Quick Dispatch freight between Boston and New Haven, performing eminently satisfactory service.

So general has been the application of the Duplex Stoker to modern locomotives, and so satisfactory has been their performance

in all classes of service, that they have established themselves as a standard and integral part of the modern locomotive.

Good steamers, quicker over the road, more tonnage hauled per train, and less time on the fire-cleaning pits are reasons why there now are—

NEW POWER

BUILT FOR THE NEW YORK, NEW HAVEN & HARTFORD RAILROAD

Total Weight of Engine, 328,000 pounds; Weight on Drivers, 229,000 pounds; Diameter of Driving Wheels, 60 inches; Boiler Pressure, 200 pounds; Cylinders, 27 x 30 inches; Maximum Tractive Power, 53,000 pounds

IF the theory were true that "*Stabilized prosperity depends on supply and demand alone,*" economic conditions existing in this country today could not prevail. The enormous supply and insatiable demand which we possess have failed to stabilize our commercial activities.

It is perfectly obvious that there is another, even more vital, requirement needed before we can get and hold the benefits of today's vast opportunities. **Distribution—prompt, efficient and constant, is the missing factor, and until this is restored, we cannot hope to realize our ambition..**

A complex problem must be solved. Our railroad systems must resume the extensions necessary. *Roadways should be strengthened—new and heavier power must be secured—for in larger units and greater tonnage lies the only solution of permanence. In no other way can the situation, which may rapidly grow more acute, be met.*

*More than half a century's experience
qualifies us to make your problem ours.*

AMERICAN LOCOMOTIVE COMPANY

We Work With You

We grew right up with the Railroads and always made it our business to try to give them just what they wanted in steel plates.

All reasonable specifications have been met, we have specialized in Boiler and Firebox plates, and we can give the great widths necessary for plates used in the construction of modern engines, so that troublesome seams may be avoided as much as possible.

BALDWIN

**Maximum Efficiency
at Minimum Cost for Maintenance**

ADEQUATE power is vital to the success of any railroad company.

But adequate power, if it involved excessive maintenance costs, would be prohibitive.

The basic design of a locomotive may be correct. It may have ample steam generating capacity and tractive force for the work to be done, but its detail parts may be so designed, constructed and located as to make its operation a constant annoyance and its maintenance a prohibitive expense.

Your new locomotives must be designed to develop maximum efficiency with a minimum charge for maintenance. Every detail part used in their construction should be carefully designed and proportioned for the work it has to perform.

BALDWIN SERVICE, which covers everything in locomotive engineering—from a study of your operating conditions to the design of the smallest details used in your new engines—will guarantee the fullest satisfaction to your master mechanic, your round house foreman, engineers and others responsible for securing the best results from your motive power.

30 Church Street, N. Y. City

This agitator, as its name suggests, agitates the water as it passes through the tube, making every particle of water as hot as every other drop.

THE HEAT SAVER

Our Type "E" Feed Water Heater has one major function to increase locomotive capacity by reclaiming heat.

Heating the cold feed water by passing it through brass tubes surrounded by exhaust steam gives the boiler more steam making capacity.

Spiral corrugated brass agitators, the full length of each tube, bring each particle of water into intimate contact with the hot tubing.

This means rapid heat transfer.

Each particle of feed water reclaims heat from the exhaust steam.

It is this system of agitators that give the Type "E" heater its capacity increasing power.

Locomotive Feed Water Heater Co.

Figure the blow on the driving boxes with every revolution of the drivers. Its enormity will surprise you.

Franklin Automatic Driving Box Wedge

TWO PART WEDGE— AND WHY!

Franklin Automatic Driving Box Wedges are made in two parts. Primarily because a solid wedge—spring held—would stick and bind the driving box.

The floating member is the reason why the Franklin Automatic Wedge maintains driving box-adjustment and does not stick.

It has vertical movement, a fraction of an inch, in which it goes with the driving-box up or down.

Between the two wedge sections the taper is less than between the wedge and the frame. Yet it is tapered.

This floating member relieves the spring held member and prevents jamming solid between the frame and box.

The combination maintains adjustment with every revolution of the drivers.

This veteran has stood punishment. It has protected the flues and staybolts from cold air. It has mixed the gases and prevented the escape of many steam-making heat units.

HELP

Arch tubes increase the boiler circulation and maintain more uniform temperature of firebox sheets.

Security Arches maintain more uniform firebox temperature in the firebox and prevent cold air striking the firebox sheets.

This constantly uniform temperature prevents the unequal expansion of firebox sheets and reduces flue and staybolt leaks.

It's less work to apply and maintain an Arch than it is to do the flue and staybolt work the Arch avoids.

Any Locomotive Worth Operating is Worth Superheating

All new locomotives and the majority of the locomotives in service are equipped with superheaters.

There are, however, numerous saturated locomotives in operation that are well worth superheating.

Equipping these old locomotives with our superheaters effects a saving of millions of dollars a year in locomotive fuel.

Regardless of the service in which they are used, if these old locomotives are worth operating they are worth superheating.

Repaired in five hours

MAINLY through the portability of Prest-O-Lite it was possible to weld the base of this heavy railroad crane in a few moments less than five hours.

That's the usual quick way in which it is possible to weld with Prest-O-Lite and the oxy-acetylene process.

Through the use of Prest-O-Lite it is possible to weld, build up and cut metals without bringing the work to be done to a workshop.

Thus Prest-O-Lite, the Universal Gas with the Universal Service, provides the means for moving an oxy-acetylene welding outfit *anywhere* and *everywhere*.

You will be interested in the Nation-wide Service of our forty plants and warehouses.

TORONTO

You're burning up money

if your average rivet spoilage by burning and scaling is the usual 15%

You can stop this waste and effect other economies—

at the same time improve working conditions—by installing Berwick Electric Rivet Heaters.

We've used 50 of these heaters in our own shops for six years. One hundred and fifteen other manufacturers are using them—495 heaters altogether.

They have proven economical in operation, consuming not more than 20 kilowatt-hours per hundred pounds of rivets heated. They eliminate smoke, fumes, dirt, and excessive heat radiation. They produce hot rivets in 20 to 30 seconds after starting. They are conveniently portable, simple to operate and safe.

Nine standard types and sizes for all rivets up to 1½" x 10" or larger; capacities up to 600 hot rivets per hour.

Investigate Electric Heating of Rivets!

Send for catalogue. Please state rivet requirements and alternating current conditions.
